In the Brook Hirst solenoid type starter, which it is claimed combines the advantages of both types without their disadvantages, the fixed contacts are of carbon mounted in stamped holders. Behind each carbon is a spring which ensures the requisite pressure between the fixed and moving contacts. The moving contacts consist of a bar actuated by a single solenoid, but in such a way that it approaches each carbon with a direct butt movement, so that contact is established instantaneously over the whole area of the

Fig. 2.—The Contacts and Movements in the New Brook Hirst Starter.

carbon (see Fig. 2). In the course of its further movement the bar presses the carbon home into the holder, and subsequently there is a slight sliding movement which tends to clean the contact surfaces. This action is repeated on each step and, there being one solenoid only, it is possible to provide economically an ample number of steps.

The advantages claimed for this movement are several. With designs employing a sliding contact, there is a noticeable tendency when starting up for the starter arm to stick owing to the contacts becoming pitted. Such a tendency is said to be impossible with the design under consideration, and the necessity for constant supervision and adjustments is thus avoided. The number of starting steps being always adequate to the output, the acceleration of the motor is gradual and it benefits by the elimination of excessive current peaks. The absence of arcing on the contacts means that they require renewing at rare intervals only.

The Timing of the Movement.

The timing of the starter movement is effected by an eddy current retarder. The solenoid plunger acting through a rack and train of gears causes an aluminium disc to revolve between the poles of an electro magnet which is excited by the main armature current. The eddy currents generated in the disc exercise a braking effect upon it and upon the plunger. As this effect varies in direct proportion to the starting current, the retarder provides the vital characteristic of quick starting with light loads, and slow starting with heavy loads. Unlike the oil dashpot the retarder is unaffected by dirt or temperature changes, nor does it continue to exercise a braking effect when the starter arm is returning to "off." Since the contact springs also tend to force the arm to the "off" position, there is, the makers claim, a positive return and no possibility of the arm sticking on the backward movement. Apart from the automatic variation of the braking effect with the load, it can also be adjusted for normal starting conditions by regulating the distance between the poles of the electro magnet.

Reliable Governing Obtainable.

The possibility of governing the movement of the starter electromagnetically in this way, instead of by a dashpot, means a great increase in reliability. A heavy overload during starting may result in a complete interruption, temporarily, of the starting operation, thus avoiding an excessive rush of current such as might damage the motor. And finally the lack of necessity for constant attention and adjustment effects a by no means negligible saving of time on the part of maintenance staff.

The starter is not normally arranged for "inching," though this may be carried out by the use of the "starter" and "stop" buttons in sequence. Where, however, the operation is to be an important function of the starter, a special "inching" device can be employed. This enables "inching" to be effected without the starter arm

coming into action. The "inching current" can be varied within prescribed limits by means of the links and terminals provided.

Operation on Overload.

It will be seen, then, that the starter is designed to prevent damage to the motor during starting, since it slows down or interrupts the starting operation on an overload. Under any given conditions of load the time in which it will start up the motor can be predicted, the element of unreliability being thus eliminated. Finally its movement permits an adequate number of starting steps to be employed while retaining a butt contact, and the consequent absence of sparking and incidental difficulties. As has been previously indicated, this starter constitutes the central feature of an ironclad panel which comprises in addition a double-pole circuit breaker and a double pole isolating switch. The former, consisting of two magnetic blowout contactors and two solenoid type overload trips, provides, it is claimed, complete protection for the motor both during starting and running. The overload trips may be adjusted to trip at any given overload, and they may also, if desired, be arranged with an adjustable timelag, so as to avoid the circuit being opened by reason of a momentary excess of current. The isolating switch, which is fitted in a sealed compartment with external operating handle, is interlocked with the doors in such a way that the latter cannot be opened or left open unless the isolator is "off" and the panel "dead"

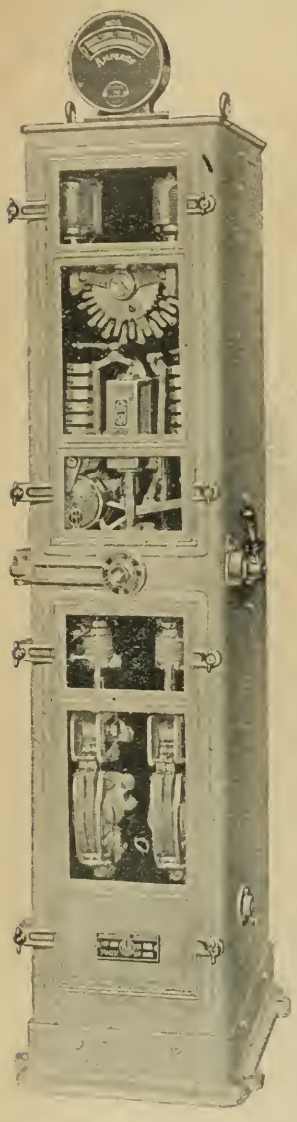

Fig 3. — Solenoid Type Variable Speed Panel (Automatic Regulation), with Ammeter, in Pillar Type Case.

Application to Printing Presses.

For certain applications (*e.g.* to printing presses) it is not, as a rule, necessary to effect speed changes at the work itself, but the speed having once been set it must be possible to start, stop, and "inch" the motor frequently, the speed at each restart always reaching and finally remaining at the set speed. In such a case a regulator of the automatic acceleration type provides the desired facilities. In this case the regulator is adjusted by hand to the required speed, if necessary while the work is in progress. On restarting, after normal speed has been reached, the motor automatically accelerates to the speed which has been set. The accelerator bar and contacts which achieve this object also cut out the whole of the shunt resistance on stopping, so that on restarting or "inching" it is not necessary previously to bring the regulator handle to the "all resistance out" position.

Complete Control of Speed.

While for a wide variety of services the speed regulating facilities outlined above are ideal, there are some conditions where it is desirable to have complete control of the speed by push buttons at the working position. For these applications a panel such as that illustrated in Fig. 3 is employed. The regulator in this case, is of the automatic type, operated by two solenoids, and it is possible from a convenient push button station to start, stop, "inch," accelerate or retard the motor.

It is also possible to employ a third system of speed regulation, using a constant speed panel as shown in Fig. 1 The regulator can then be arranged either with a pedestal, as shown, or for wall mounting, and can thus be placed in close proximity to the work.

This arrangement is intended for applications where it is necessary to effect speed adjustments at the work itself, but not to start and stop frequently. Each time the motor is started or "inched," the regulator must be brought to the "all resistance out" position, and when normal speed is again attained the regulator must be readjusted to give the required speed.

Rotary Converters.

We give below an account of the discussion which took place at Birmingham on Mr. F. P. Whitaker's Paper on "Rotary Converters, with Special Reference to Railway Electrification." An abstract of the Paper appeared on p. 258 of our issue of March 3.

Mr. R. A. Chattock said that Mr. Whitaker apparently put efficiency before reliability. To supply station engineers, however, reliability was of the first importance and railway engineers would probably think the same. With reliability was wrapped up simplicity and he was convinced that it would be better to sacrifice 1 or 1½ per cent. efficiency if greater reliability and simplicity of operation could thereby be obtained. Mr. Whitaker had pointed out how the maximum direct current voltage obtainable increased with the reduction of the frequency. This was an important point in favour of 25 periods, as the number of substations required would be reduced. To run two rotary converters in series meant complication, especially for automatic operation. He considered that high speed circuit breakers would cause surges and insulation breakdowns, unless special steps were taken to prevent voltage rises. Mr. Whitaker had rather hinted that something was to be gained by using 50 periods, and he would like to know what that was, as although the initial cost of low frequency plant might be heavier, it would not really affect the working results and in other ways it had distinct advantages. He considered that automatic operation would be a necessity for railway work, and the initial cost of the automatic rotary equipment was about double the cost of the ordinary equipment. This might seriously militate against its adoption when compared with the mercury arc rectifier.

Short Circuit Phenomena Explained.

Dr. M. Kahn said that short circuits were the principal point to consider in the design of traction rotary converters. When a short circuit occurred on the direct current side of a rotary protected by ordinary circuit breakers, the current increased from five to twenty times normal full load current in about 1/2 000ths of a second. This overload caused a deceleration of the armature, so that a considerable part of the energy given out was supplied by the moving mass, and not from the alternating current side. This meant that the alternating current did not increase so rapidly as the direct current, and thus caused a large increase in the armature reaction, and the putting out of action of the commutating poles, unless special precautions were taken. Thus violent sparking occurred. When the direct current circuit breaker opened the heavy current on the direct current side was interrupted. The voltage between the brush arms rose and a flash over was caused, partly owing to the unbalancing of alternating current and direct current in the armature in the opposite direction from that just described. At the same time there was a rush of alternating current, and this caused a considerable increase in the armature reaction and violent sparking. The phenomena was akin to hunting, and flash overs might occur in rapid succession until the machine was cleared on the alternating current side.

Ill-Fitted for A.-C. Traction.

Prof. W. Cramp said that the Paper demonstrated that compared with the motor converter, the rotary converter was ill fitted for traction work. The author had omitted all mention of transformers and connections, and he was not sure whether they were included in the efficiency and power factor curves in the Paper. The author gave too few technical data to make it possible to criticise his oscillation limits, but it was difficult to see how distinctions could be drawn between flux pulsation and flux swinging, and what was meant by saying that reactance tended to keep the tooth oscillation up so that the tooth ripple need not exceed ½ per cent. of the voltage ripple.

The 12-Phase Rotary.

Mr. F. W. Carter asked whether Mr. Whitaker had considered the 12-phase rotary, which gave an armature loss of 21 per cent. of that due to direct current alone, while the 6-phase rotary gave 27 per cent. The loss in the coils next to the taps was 18 per cent. greater than the mean in the 12-phase rotary, against 57 per cent. in the 6-phase machine. Reactance voltage was more uniform, so that the conditions for commutation would be better, though against this must be set the disadvantage of having twelve slip rings instead of six.

A Word for the Rectifier.

Mr. F. Forrest considered that the mercury vapour rectifier was a much more desirable unit for high voltage traction than the rotary converter. It was more efficient, cheaper in first cost, and perfectly reliable for a period of years. The modern rotary converter was the product of twenty years' experience, while the mercury vapour rectifier had only been on the market for a comparatively few years. The maintenance of the proper vacuum was undoubtedly a problem, but that was certain to be overcome. The cost of a fully automatic rotary converter substation was twice as great as the manual controlling, and it was difficult to see how this cost could be justified.

Correspondence.

TRANSMUTATION OF ELEMENTS AND ATOMIC ENERGY.

To the Editor of THE ELECTRICIAN.

Sir,—Notices have recently appeared in both the lay and technical press referring to the recent experiment of Dr. G. Wendt and Mr. C. E. Irons of the University of Chicago, in which a temperature of 50 000°F. is stated to have been obtained and a transmutation of the tungsten atom into helium to have been effected.

It would appear that some of the great heat and very intense light generated should be due, theoretically, not only to the original energy of the large highly-charged condenser used, but also to the atomic energy set free in the transformation from tungsten to helium.

One wishes to suggest that the method which is described as being employed by these experimenters may also be used to hasten the disruption of the radium atom.

By using a small tube of tungsten having a very fine bore as the conductor to be disrupted by a sudden large condenser discharge, and by enclosing in this bore a small quantity of radium salt, this material should be caused, one believes, to evolve all its stored energy in a short time, possibly leaving helium alone or together with lead as its sole survivor.

The experiment may be one of very great danger and some form of remote control gear operated from a distance might be used to cause the discharge of the condenser, the whole apparatus being located in a somewhat remote spot to ensure safety to the surrounding district. Also the possibility of the spreading of an atomic disruption, when once started to other masses of matter in the vicinity should be kept in mind.—Yours, &c.,

Brixton, April 18th. W. J. RICKETS.

Metropolitan-Vickers' New Zealand Contract.

We are able to give further particulars of the announcement in our last issue of the contract secured by the Metropolitan-Vickers Company from the New Zealand Government for generators and switchgear for the new MANGAHAO POWER STATION. This station forms the first of a series dotted throughout the whole of the North Island, which will finally be linked up by transmission lines at 110 000 V and roughly form a ring round the southern portion of the island. The order includes the supply of three 6 000 kVA and two 3 000 kVA water-wheel generators working at 11 000 V, three-phase, 50 cycles, 0·8 power factor, and driven by overhung water-wheels with horizontal shaft running at 375 revs. per min. Each generator will have its own direct-driven exciter, and in addition provision is being made for a stand-by motor-driven exciter, set so that when necessary the excitation of one or more generators can be transferred to an auxiliary exciter bus. Cooling air for the generators will be drawn through a separate ventilation tunnel, circulation being maintained partly by a separate blower and partly by the usual fans on the rotor, the blower being designed to keep 2 in. pressure. The generators are designed for an overspeed of 80 per cent. and will have a regulation of 27 per cent. at 0·8 power factor. Provision will be made for sliding the stators so as to facilitate access to the rotor when necessary for inspection and cleaning work.

Switch Details.

The current from the generators will be taken through automatic oil switches of the Metropolitan-Vickers "H.F. 2" type, through selector switches to duplicate 11 000 V bus-bars. Both bus-bars will be sectionalised in the middle, and this sectionalising is carried out correspondingly on the 110 000 V bus, so that the whole system can, if necessary, be split into two entirely independent portions. From the generating voltage bus-bars supply will be taken through two 12 000 kVA transformer banks to the 110 000 V bus-bars, and thence to the four outgoing 110 kV feeders. There will be four local feeders at 11 000 V. The 11 000 V equipment will be located in a conventional moulded stone cubicle structure. The e.h.t. switches for controlling the transformer sides will be indoors, while the isolating switches, oil circuit breakers, and lightning arresters for the feeder circuits will be accommodated on the roof of the power station In this way the total ground space occupied is kept down to the minimum. Each generator and transformer unit will be protected by the usual circulating current system, while on the 110 000 V feeders there will be fitted the new Metropolitan-Vickers' compensated overload relay, which is designed to give an inverse operating time characteristic with a definite adjustable minimum. In addition the pairs of feeders will be protected by balanced biased relays, which will operate in the event of the failure or short-circuiting of either feeder.

This order marks a definite period in the history of switchgear development in this country, in that it is, it is claimed, the first placed for British-built material for so high a voltage. We have already referred in our columns to the developments which the Metropolitan-Vickers Company are making in this direction, and at a later date hope to publish more complete details of the scheme now referred to.

Mr. Robert McDougall has intimated his desire to defray the cost, £5 000, of equipping a RADIOLOGICAL DEPARTMENT at Manchester Royal Infirmary as a memorial to his father, the late Mr. Arthur McDougall

Lancashire Electricity District.

The Electricity Commissioners notify that, having considered the evidence given at the inquiry held in January last into the scheme for the establishment of a SOUTH-EAST LANCASHIRE ELECTRICITY BOARD and the representations made by various bodies for the inclusion in, or exclusion from, the district of their respective areas, they have come to the following conclusions :

The Commissioners entertain some doubt as to whether the provisions by which the Advisory Board will make representations to constituent authorities, with a right of appeal to the Commissioners, whose decision (within strictly defined limits) will be binding on the constituent authorities, will enable sufficiently comprehensive works to be undertaken. They apprehend that there may be a tendency to proceed by piecemeal extensions of stations and interconnecting lines at an ultimate increased cost to the constituent authorities and the consumers concerned. An Advisory Board may also experience difficulty in securing supplies in unoccupied areas, more especially in those contained in the enlarged district south of the Manchester Ship Canal, for which a Joint Electricity Authority would be empowered to make provision. In view, however, of the unanimous support given to the scheme by the authorised undertakers, and of their strongly expressed opinion that this voluntary arrangement is the best in the particular circumstances of the district, the Commissioners are prepared to make an Order embodying the arrangements which the constituent authorities have agreed to carry out.

Area and Administrative Scheme.

The Commissioners confirm the area provisionally determined, subject to the exclusion of the urban districts of Lymm (Cheshire) and Haydock (Lancs), both of which are now included in the Mersey and W. Lancashire district, and the inclusion of the urban district of Adlington (inadvertently omitted) and of the municipal boroughs of Buxton and Macclesfield, the urban districts of Bollington, New Mills and Yeardsley-cum-Whaley, the rural districts of Macclesfield, Hayfield and Disley, and the parishes of Chapel-en-le-Frith, Chinley, Bugsworth and Brownside, Fernilee, Green-Fairfield, Hartington-upper-Quarter, Kingsterdale, Peakforest and Wormhill.

The title "South-East Lancashire Electricity Board" is inappropriate and is liable to be misinterpreted, having regard to Sec. 8 of the Electric Lighting Act, 1909, and the more appropriate title would be "South-East Lancashire Electricity Advisory Board." The number of representatives on the Board is unnecessarily large. If the authorities in the district are unwilling to reduce the size of the Board, the Commissioners will be prepared to include in their Order the proposal submitted in the second schedule to the amended scheme, subject to certain modifications consequent upon the agreed representation of the Stalybridge, Hyde, Mossley and Dukinfield Tramways and Electricity Board, and upon the increased area of the district. Having regard to the representation to be given to local authorities who are not authorised undertakers, as provided in the scheme, the Commissioners consider it unnecessary that county councils should be represented on the Advisory Board. The engineer of the Stalybridge, &c., Electricity Board should be a member of the Engineering Advisory Committee, but, having regard to the non-standard frequency of the Stalybridge system, he should be entitled only to attend the meetings of the Committee when electrical developments and proposals are to be considered which may affect the area of the Stalybridge Board and the areas contiguous thereto. The Yorkshire Electric Power Company will not be required to furnish plans of new works to the Board, but only to furnish such statistics as may refer to supplies given by the company within the urban districts of Saddlesworth and Springhead.

Technical Scheme.

The Commissioners approve generally the technical scheme submitted to them, subject to a provision that modifications thereof may hereafter be made with the approval of the Commissioners. The scheme includes provision for the giving of advice and assistance to the Board by the Engineering Advisory Committee on (*inter alia*) the adjustment of running hours of the generating stations in the district in such manner as to secure maximum economy of production, and on the principles which should govern the charges to be made by, or between, constituent authorities for reciprocal, stand-by and bulk supplies. In the event of disagreement between the Board and any constituent authority there is a right of appeal to the Commissioners, whose decision, subject to specified reservations, is to be binding on the parties.

Notwithstanding these provisions, the Commissioners are of opinion that the actual direction of the times and method of working of inter-connected stations so as to produce the most economical results will be best effected by an officer of the Board appointed for that purpose, who would carry out the programme of working laid down by the Engineering Advisory Committee and approved by the Board; a scheme of control of generating stations following the above-mentioned lines should be submitted for the approval of the Commissioners. The Commissioners will include in the Order a provision requiring the Board, within two years from the date of its establishment, to submit proposals for securing a supply in areas within the district which are not at that date within the areas of supply of authorised distributors and in which there is a reasonable prospect of such supply being remunerative.

Political Finance.

Its Devastating Effects on Trade.

The interest for the business man in THE GENOA CONFERENCE is not in the way in which the various delegates are manœuvring for position or in the extraordinary rapidity with which the political kaleidoscope revolves and changes, but rather in the emergence of the long-delayed hope that an economic sense, a return to financial sanity, seems at last to be in prospect.

It will indeed be a strange, if a fitting, conclusion to the mixture of drama and comedy which goes to make up the history of Europe in the last few years if the Bolsheviks should for a time occupy the centre of the stage and complete their mission, giving to the world one brief, great, and awful demonstration of the utter futility of what may be described as "political finance." These madmen, at the frightful cost of millions of their own people, have already given to humanity an object lesson of the result of infringements of economic law, from which the world of the future must derive untold benefit, and if now they add to their ruthless exposure of the idiocy of communism a practical demonstration of the impossibility of the economic war, they may be recognised in centuries to come as important constructive factors in the development of civilisation.

The Object of the Genoa Conference.

The Genoa Conference is assembled to discuss economic questions and to debate once again how much money certain countries shall pay and how much other shall receive, a discussion, the absurdity and impracticability of which I have never ceased to argue. Trade, industry and commerce cannot again resume the full measure of their service to mankind until the politicians cease meddling with the medium of exchange. So long as political conferences continue to discuss the allocation of large sums of money between different nations and different parties, so long will money fail to exercise its proper functions, and so long will trade and commerce remain almost an impossibility.

The difficulty is that politicians, like, indeed, most human beings, have the flimsiest conception of the character of this thing called money, about which they talk so glibly and decide so lightly. If the Prime Ministers of Europe were to collect all the violins in existence and distribute them among professors of mathematics, they would be acting with about as much sense as when they attempt to settle political problems through the medium of exchange. Money is a medium of exchange which was created and perfected by commercial men for the purposes of commerce; it has no real use except in connection with the exchange of commodities; it ceases to be money when it fails to represent realities. The trouble is that the machinery of exchange has been brought to such a pitch of scientific perfection that it is possible for people for whose use it was never intended, like gamblers or politicians, to get hold of it and use it for purposes for which it is utterly unsuitable; and the worst of it is that in so using it the politicians or gamblers cannot avoid the exercise of a very damaging influence upon all those who are concerned in the use of money for its proper and legitimate purposes. We are gradually learning our lesson; the next generation will accept as an article of faith the unalterable truth which this generation is not yet quite able to see—that the divorce of money from exchange is a crime, and the worst form of crime, inasmuch as it damages not only those immediately concerned in its perpetration, but every human being in existence at the time that it is done. There is no difference between some of the decisions of the Allied Conference and the realm of finance and Kruger's historic demand for moral and intellectual damage.

The true import of Kruger's innovation was not realised at the time because he was dealing in very small figures; but when the Bolsheviks put forward a claim for £1 500 000 000, the essential fallacy of the whole business becomes apparent. The error is at bottom exactly the same as that contained in such proposals as the capital levy, or work, or maintenance, and is seen in a slightly different form in the iniquity of the printing press.

An Impossible Situation.

The business man, who as a business man is not in the least concerned with the political manœuvres at Genoa, can see these things a little more clearly than the general public. For instance, if it is right and proper that Czecho-Slovakia, which may, without offence, be described as the Ireland of Austria, should receive financial consideration in respect of the part which it played in the war, there can surely be no objection to interpreting in terms of money the service rendered in the same cause by the Russian steamroller. The truth is, of course, that neither case can be settled on a cash basis. The absurd results which have already accrued from this attempt to assess war claims in the medium of exchange are demonstrated for the benefit of all who care to study the matter of the present price of money in Central Europe.

I journeyed through six countries a few weeks ago, and changed sovereigns for 48 francs in France, 55 francs in Belgium, and 350 marks in Germany, but the gross stupidity of it all is illustrated still better by the position of the old Austrian crown. The same crown which a few years ago was worth, roughly, 1s., stood in Austria proper at 32 000, in Hungary at 3 500, and in Czecho-Slovakia at 320. The difference between 32 000 and 320 was not even a difference of form, the same piece of paper serves for both crowns, the mere addition of a red ink stamping impressed to the order of the politicians makes one paper chit worth 320 and the other worth 32 000.

If the traveller will board the Ostend-Constantinople express, which now runs daily, he can drink a cup of coffee out of the same pot, or eat a slice of meat off the same joint, without even changing his seat, and pay nine or ten different prices for the same article, the price being regulated by the country into which the train happens to have wandered. I know of no illustration which more graphically exposes the impossibility of the situation.

The Germans and the Bolsheviks may have been guilty of treachery, they may be devoid of all sense of honour in negotiation, they may be unworthy to sit at the same conference table with more orthodox diplomats. These are questions of which I am no judge; but in deciding, as they appear to have done, to wipe out between themselves all indemnities, all reparations, and all sums of money which do not represent exchange for value given, they have set an example which, sooner or later, the rest of us, although we may not yet have reached a state of mind in which we are prepared to realise it, will be bound to follow.

We are now nearer than ever to the happy day when money and finance will be understood as the special province of the business man; when the world will understand that war has nothing to do with business, and that the machinery of business cannot be made to clear up the messes of war; the two things are as wide apart as the poles. When we have learnt that lesson, and it seems as if we are now beginning to do so, trade, commerce, industry, and all that makes for civilisation, will once more resume their beneficent service to mankind.

E. J. P. B.

Grampians Electricity Supply Scheme.

Some progress has been made by the GRAMPIANS ELECTRICITY BILL, which has now passed its second reading in the House of Commons, and it will probably come before a Select Committee in the first week in May. The promoters (The Hydro-Electric Development Company) have made arrangements with some of the petitioners against the Bill, and negotiations are being conducted with other opponents.

For some time informal discussions have been proceeding between the promoters and representatives of Dundee Corporation in regard to the proposals submitted by the Company. These included an offer by the Company to pay the Corporation £25 000 per annum to cover annual charges for sinking fund and interest on the capital expended on the power station, and to supply electricity at £3 7s. 6d per annum per kW of maximum demand up to a maximum of 25 000 kW, plus 0·2d. per unit delivered, all demands above the maximum to be supplied at £3 5s. per annum per kW, plus 0·2d. per unit. The agreement would be for a period of twenty years, each party to have a right to call for the revision of charges at the end of five years. The Corporation should grant a lease to the Company of Carolina Port Station at a rent of £25 000 per annum, and the Company would supply the whole of the electrical requirements of the Corporation in bulk from the station, or partly from the station and partly from certain sub-stations, the Corporation guaranteeing a maximum demand of at least 12 000 kW.

The suggested agreement contained other conditions, but at a special meeting of Dundee Town Council last week it was decided, on the motion of Mr. R. F. Sturrock, convener of the Electricity Committee, to reject the Company's offer as the inducements offered were not sufficiently favourable to the Corporation.

Oswestry's Electricity Charges.

The application of the OSWESTRY ELECTRIC LIGHT & POWER CO. for power to increase their maximum charges for electricity from 8d. to 1s. 3d. per unit was the subject of an inquiry last week by Colonel T. C. Ekin, a commissioner appointed by the Electricity Commissioners. Opposition was offered by the Corporation and Oswestry Traders' Association. For the Corporation, the TOWN CLERK protested that the company had already increased its charges to the maximum amount now asked for without sanction having been given, and that for the past three years consumers had had to pay more than the statutory price authorised by the company's Provisional Order. The maximum price now asked for was in excess of the charge for electricity in other towns in the district. It was important that the period for any increase, if granted, should not exceed three years. Firstly, because it was reasonable to suppose that the cable from Dolgarog, North Wales, would be laid in Oswestry before the end of next year, when the price for current in the town would be 2d. per unit or less. Secondly, because the Corporation had the power to acquire the undertaking in 1929, at the then fair market value, subject to a payment in addition to the value of the works of a sum equal to the net profits of the undertaking for the then preceding three years. If this increased maximum charge was sanctioned, enabling the company to charge this maximum during the last three years, it might cause the price to be paid by the Corporation to be a sum considerably in excess of the actual value of the work and plant.

Mr. W. K. MINSHALL, for the company, said there had been no profiteering, and the increase already made in the charges was not in any way in proportion to the increased cost. The charges (net) in 1914-15 for light was 6¾d. per unit, raised in 1921 to a net charge of 1s. 2¼d., an increase of 111 per cent. On the other hand, the costs had increased 244 per cent. He hoped the Commissioners would grant the application, and make it retrospective to 1918.

The Commissioner: That is quite impossible. No order can be made retrospective.

Alderman E. BREMER SMITH, engineer to the company, said he was sorry to hear that. If they had to reimburse what they had overcharged the last three years it would come to over £8 000. Their capital was only £8 000, and it would mean that the company must go into liquidation.

The Société des Ingenieurs-Civils de France.

In his presidential address to the British Section of the Société des Ingenieurs-Civils de France last week, at the Institution of Mechanical Engineers, London, Mr. W. Noble Twelvetrees said that the essential objects of the British Section were to provide for the establishment of closer relations between members resident in different parts of Great Britain and the British Empire, and to encourage professional and friendly intercourse between French and British engineers generally. The first President of the British Section was Mr. C. H. Wordingham (Past-President of the Institution of Electrical Engineers). The Section was formed soon after the war, and at its first meeting it was pointed out that it might help towards the attainment of intercourse between French and British engineers by drawing into the ranks of the French Society as many members as possible of the engineering institutions in this country, and, at the same time, by working for the recruiting of French engineers as members of British engineering institutions. The first of these suggestions had met with a most promising response, for the membership of the Section was now approximately three times that existing at the date when the Section was formed. Further, the membership was thoroughly representative of all classes of engineers, and included, in addition to Mr. Wordingham, Mr. Roger T. Smith and others on the electrical side. The suggestion that French engineers should be invited to offer themselves for membership of British institutions was one that the Section would gladly attempt if the idea were approved by the institutions concerned. One difficulty which had in the past prevented many young French engineers from joining British institutions was that the qualifications for associate membership usually included the passing of examinations or the possession of an approved diploma or certificate exempting candidates from examination. It was desirable, therefore, that the equivalence of French and British engineering diplomas and certificates should be determined, with the object of preparing a list of French qualifications which would be accepted by British engineering institutions, in every case with due regard to special requirements, as exempting candidates wholly or in part from the examinations prescribed.

The Work of the Section.

Dealing with the work of the Section, Mr. Twelvetrees said the President of the Section had represented the parent Society at various meetings and functions of engineering institutions and societies in London and the provinces, and arrangements had been made with engineering firms in Lorraine to accept a few British engineering students for periods of three months during the summer, so that some experience might be gained of French engineering practice.

After dealing with the interchanges between French and British engineers, and suggesting that they might be more frequent, the President said it appeared to him that if the engineering institutions on both sides of the Channel were once effectively organised, the next step should be the formation of a Franco-British committee, whose special business it would be to consider all possible means of bringing into closer touch the engineers of the two nations. Such a scheme could well be spread to other countries, and he mentioned that an American Section of the Société des Ingenieurs-Civils de France had been formed.

In response to an invitation from the President to express their views on this question of co-operation and federation, a number of engineers took the opportunity to do so.

Difficulties of Co-operation.

Mr. C. H. Wordingham said there were serious difficulties in the way of producing a workable scheme for the federation of engineering institutions in this country, mainly due to the jealousies and opposition of the smaller societies, who felt they should not be left out. Whilst he agreed that they should not be left out, it was not practicable that all of them could be represented on a central body directly. Therefore he suggested the grouping together of these smaller societies so far as they dealt with a particular branch of engineering, and then federating the groups representing that branch under a main institution. The main institutions could then be federated together in the Grand Council of the whole engineering body of this country. During the war a Committee of the Conjoint Board of Scientific Societies was formed, under the chairmanship of Sir Robert Hadfield, which made great efforts to acquire the site of the old Stationery Office for the purpose of erecting a central building for the engineering institutions of the country. He (Mr. Wordingham) was a member of that committee. The site in question was the only one that would have enabled a joint building to be erected in conjunction with the existing buildings of the Institutions of Civil and Mechanical Engineers, which it was felt were too recently erected to think of abandoning, and also it was felt that such a joint building should be in Westminster, the office home of engineers. The Government, however, would not part with the site.

A Central Library.

Not the least of the many advantages of such a scheme would be a central library, to which could easily be attached a bureau of technical information, because at the present time there was a lamentable waste of effort in connection with the abstracting of articles of an engineering and technical nature. As to co-operation with other countries, he advocated a start with the Allied nations. Also, it was important that British firms should take French pupils, and that the qualifying examinations of British and French institutions should be rearranged, so that a British engineer, having passed the qualifying examination for an institution in this country would be accepted at once as a member of a similar French institution and *vice versa*.

Captain H. Riall Sankey (Past-President, Institution of Mechanical Engineers) said that progress had been made at the conference between the Institutions of Civil, Mechanical, and Electrical Engineers and Naval Architects, and that details of a scheme of co-operation would be published before long.

Mr. W. H. Patchell referred to the intention of the Institution of Mechanical Engineers to hold its summer meeting in Paris this year, and said that the latest information made him rather doubt whether the Institution would be able to carry out its intention, because the prices charged by hotel-keepers in Paris were rising so enormously. Whilst he upheld the principle of federation, he did not think that we in this country could get anything approaching the federation that existed in America, which would be altogether too unwieldy for us, and he believed it would soon be too unwieldy for America. He believed the tendency in all countries in future would be for the engineering institutions to pay more attention to men than materials. He agreed with Mr. Wordingham as to the amount of money misspent in abstracting, notwithstanding which it was impossible to get decent abstracts.

The next meeting of the British Section will be held in June, when the projected lateral canal to the Rhine will be discussed.

On Mr. Matthews' Farm?

"Oh, Sir, something has gone wrong with the electric milker, and one of the cows has got charged with electricity."

(By kind permission of the proprietors of "Punch.")

The Stylolectric Pen.

The Stylolectric Pen, which has recently been on view at Selfridges, is a most attractive and useful device. It is no larger than a fountain pen, and is so insulated that neither the user nor the material can be harmed. Only the point of the pen is heated, the holder never even gets warm. For use, it simply has to be attached to any ordinary electric light socket. It operates equally well on any voltage—a.c. or d.c. circuit—and its heat can be regulated to any degree. For marking wooden packing cases, leather goods, tennis balls, &c., it is invaluable, and is becoming recognised in the jewellery and electrical trades as the smallest, efficient, self-heating soldering iron. As a cauterising instrument it is also finding favour with doctors. With the aid of coloured transfer papers, which are supplied by the makers, the Post Electric Company, New York, artistic patterns in colour can be burnt into materials of every kind, including hard rubber, bakelite, paper, celluloid, &c.

An electrophone has been installed in Sefton Park Presbyterian Church, Liverpool, to assist deaf members of the congregation to hear the sermons. A receiver has been placed in the pulpit, and from this wires are laid along the aisles and into certain pews.

Mr. Gillott and Domestic Electricity.

We understand that, owing to reorganisation, Mr. W. A. Gillott is relinquishing his position as sales manager and engineer with the Jackson Electric Stove Company.

Mr. Gillott is well known throughout the electrical industry as a champion of the cause of electric cooking and heating, but it is only those who have his intimate acquaintance who are aware of the enormous amount of work he has put in in enlightening engineers and consumers alike as to the advantages of using electricity for these purposes. A few more engineers of his experience and energy on the domestic side of our industry are necessary, and we hope that Mr. Gillott at least will not be lost to that field.

Mr. Gillott, after serving his apprenticeship with the Electrical Company, in 1906 joined the staff of the Newcastle-on-Tyne Electric Supply Company as assistant engineer for the design, erection, and maintenance of high-tension transmission lines, low-tension net works, and sub-station equipment. In 1910 he entered the consumers' and development department of the company and concentrated his attention on propaganda work for the extended use of electricity. So successful were his activities that it was necessary in three months to erect a new sub-station in what had been an unprofitable residential area in order to handle the increasing demand. In 1912 he was given a free hand to establish and work a department, with showrooms, to test the possibilities of developing the heating and cooking load over the whole area of the company, some 1 500 sq. miles.

Nothing more need be said on this point except that at the time of his leaving the company in 1920 its heating and cooking load was 15 000 kW, and was an entire financial success. It will be remembered that Mr. Gillott was invited by the late Lord Rhondda to take control of the electrical work for the National Kitchens and Restaurants of the Ministry of Food, and held the position until the Department closed shortly after the Armistice. Since his connection with the Jackson Electric Stove Company in 1920 Mr. Gillott has given close attention to the design of electrical and heating apparatus of all descriptions, a particularly interesting piece of work for which he was responsible being the equipment which is installed in the Great Northern Railway dining cars. Mr. Gillott has been closely connected with the Electrical Development Association since its formation, and is at present a member of the Council and of the Executive, Domestic, and Publicity Committees.

Mr. Gillott's present address is "Dunsinane," Hadley-road, New Barnet, Herts.

Guarantees Under the Trade Facilities Act.

A White Paper was issued last week containing a statement of the guarantees which the Treasury stated its willingness to give up to March 31 last. The total is £14 958 145, and includes :—

South-Eastern and Chatham Railway Company, £6 500 000 (25 years). Electrification of suburban lines.

Underground Railway, £5 000 000 (50 years). Enlargement of tunnel of the City and South London Railway, improvement of stations and provision of new rolling stock, and extension of London Electric Railway from Golder's Green to Edgware.

Calcutta Electric Supply Corporation, £500 000 (25 years; redeemable after 15 years). Purchase and installation of additional generating plant and buildings, additional high-tension cables and transformers, and additional direct-current mains.

Kent Electric Power Company, £15 600 (20 years). Provision of mains, transforming apparatus, and station plant.

Minehead Electric Supply Company, £4 500 (25 years). Provision of generator and overhead mains.

Wireless on Fishing Vessels.

The Fishery Board for Scotland draw attention to an article on the use of wireless on board French fishing vessels which appeared in the Bulletin of the Oceanographical Society of France dated Jan. 15 last. Despite the interruption due to the war, considerable progress appears to have been made in the extension of this means of communication to the French fishing fleet, as in the space of ten years wireless apparatus has been installed on some 200 vessels. In order to have the messages from the fishing vessels transmitted as rapidly as possible, the French postal authorities have them telephoned direct from the coast wireless station to the owners. La Rochelle is the only fishing port of importance which is not yet provided with a wireless station, although almost forty trawlers of that port are equipped with wireless. At St. Pierre and Miquelon there is not yet a sufficiently powerful coast station, but an up-to-date apparatus with a radius of 600 miles is expected to be put in commission during next season.

British Electrical Orders from Calcutta.

Orders for electrical plant, amounting in value to £500 000, are being placed with British engineers by the Calcutta Electricity Corporation under a Trade Facilities Act guarantee. Contracts in connection with this scheme, totalling about £250 000, have already been placed. Among firms to secure orders are, states the "Industrial Daily News," the English Electric Company, for a 15 000-kW turbo-generator; Stirling Boiler Company, Glasgow, for 60 000 lb. boilers; the British Thomson-Houston Company, for transformers; Hicks, Hargreaves & Company, of Bolton, for condensing plant; and Henley's Telegraph Works, for cables.

"Caeg" Miners' Electric Lamps.

Owing to pressure on our space we were unable last week to give more than a few particulars regarding the visit, on the 8th inst., of members of the Midland Institute of Mining, Civil and Mechanical Engineers to the works of the Caeg Miners' Lamps and Supply Company at Barnsley. The party were shown all over the works, which occupy about three acres and employ some 300 workpeople, and saw the lamps in their various stages of manufacture.

The lamp consists of three main component parts, the accumulator, accumulator holder or body, and lamp-holder. The holder and body of the lamp are, in the main, made of a high-grade steel, the cylindrical portion being made from solid drawn tubes cut into correct lengths and slotted at the top. The base of the body and shoulder and top of the lamp-holder are stamped from sheets and pressed to shape in 60-ton presses, as are the brass contacts and brass locking arrangement. The base of the case is then spot-welded to the cylindrical portion of the body; at the same time the shoulder and top of the lamp-holder are assembled, using the four guards protecting the glass globe as rivets. The assembled body and lamp-holders are then pickled and tinned. To the body the brass guide ring is riveted, all brass parts being machine made to gauge.

The accumulator portion of the lamp is assembled at Barnsley, but the plates are made by the company at their Lancashire works. The plates are of cylindrical form for the hand lamps and flat for the cap lamps, in which case the accumulator is carried strapped to the miner's back.

The positive plates are die cast in cylindrical form and are then pasted. The negative plates are produced by rolling, being bent to shape and burnt to form a cylindrical plate. After placing the plate in the celluloid containers and fitting the top, the whole is placed in a small lathe and the top chamfered to ensure as flat a joint as possible when the cementing strip of celluloid is placed in position. This also facilitates dismantling the cell. On completion of the cell it is filled with standard battery acid and given three forming charges, the acid removed and Jellac substituted, and two further forming charges given. It is claimed that Jellac only reduces charging effect by 1 per cent.

All bulbs are tested for c.p. before assembly, 5 per cent. by grease spot photometer and standard, the remainder by comparison with a sub-standard, visually. One per cent. of all bulbs purchased are run continuously until burnt out under artificial working conditions (*i.e.*, in periods of 8 hours, with intervals of 8 mins.), hence the life of a lamp is approximately found. This is claimed to be 500-600 hours. The glass of all lamp bulbs is tested for stresses by a polariscope. Any showing stress of any kind are rejected. The life of cells is also tested by repeated charge and discharge through a lamp. Contacts in the lamp are tested for wearing by clamping the lamp to a bench and the lamp-holder to an oscillating arm, the oscillations per hour of which is known.

Charging stands are made by the company, also charging contacts, racks, and resistances for charging boards. All drilling of component parts is done by jig, thus ensuring interchangeability. In addition to the standard type of lamp made of tinned steel, this type is also made up in brass, copper, and, for presentation purposes, in silver. Smaller types of lamps are made for official use, having cells running for 7 hours. These are, however, of a special pattern. All lamps are fitted with either magnetic locks or the old type of lead rivet, whichever is preferred.

Ban on Non-union Labour.

We regret to notice that the question of connecting consumers' premises which have been wired by non-union labour has been raised once more. On this occasion Chelmsford has been selected by the Electrical Trades Union as the place for putting a ban on work not executed by union men, for they claim to bar any of its members from connecting up to the mains of the local supply company (the Electric Supply Corporation) premises which have been wired by non-union workers.

The dispute raises points of great importance to the industry, and it has now been referred to the National Joint Industrial Council for the Electricity Supply Industry. When the E.T.U. delegates placed a ban on the connection of the premises the matter was referred to the District Industrial Council, but as the trade union representatives were unable to remove the veto, the employers' representatives on the Council withdrew in a body, and the matter is now one for the National Council.

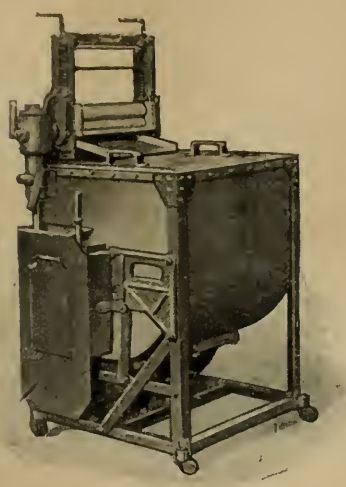
American Steam Turbine Tests.

According to the "Electrical World," recent tests made on the 60 000 kW cross-compound, triple-cylinder steam turbine installed in 1918 at the Seventy-fourth-street station of the Interborough Rapid Transit Company, show that a steam consumption of 11 lb. per kWh can be obtained under normal conditions. With the high-pressure turbine and one low-pressure turbine in service the lowest consumption was 11·25 lb. per kWh. When operating in this way the consumption is better than that for the complete set at loads below 25 000 kW. The 60 000 kW turbine is of the Westinghouse type, and consists of one high-pressure and two low-pressure elements, each element driving a separate generator. The normal steam pressure at the throttle is 220 lb. absolute, with a superheat of 150 deg. Fah., and the machine exhausts into a vacuum of 29 in. referred to a 30 in. barometer at 58·1 deg. Fah. The speed of all three elements is 1 500 revs. per min.

The "Briarton" Washer.

Arton & Walton, the manufacturers of the "Briarton" washing machine, claim that it washes, boils, rinses and wrings the clothes at a running cost of under 2d. per hour with electricity at 8d. per unit, and that a day's wash can be completed in an hour and a half. The firm have had fourteen years' experience in the design and manufacture of such machines, and the designer of the "Briarton" was closely associated with the design and manufacture of the greater part of the machinery installed by the British War Office in the huge laundry at Etaples, near Boulogne, which washed the clothes of the British Army during the War.

The "Briarton" is fitted with a special gas burner and air blast apparatus which reduces the time required for boiling the clothes to a minimum when compared with the older and less efficient form of burner with which some foreign machines are fitted.



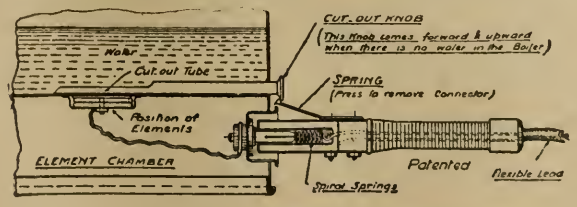
The "Briarton" Washer.

Special attention is called to the capacity of the power-driven reversible and swivelling wringer. Its 15 in. long by 2 in. diameter best quality rubber rollers are claimed to be of 50 per cent. greater capacity than many machines now on the market, and the largest household articles in the wash can be comfortably wrung.

The washing cylinder is 20 in. diameter by 20 in. long, and is built up of heavy gauge perforated zinc sheet with tinned brass ends. It has five hardwood rubbers and lifters, and is rust and verdigris proof, and runs in anti-friction bearings. The motor is totally enclosed and of ample capacity (¼ h.p.). It runs on ball bearings and drives the machine direct through the special design of friction clutch which prevents overloading. It can be arranged for any voltage, either d.c. or a.c. circuit. There are no belts to stretch and slip. The speed-reduction box contains all gears except bevel gears driving the wringer. All fast running gears are machine cut, with helical teeth, and run continuously in an oil bath. The bearings are arranged for automatic and continuous lubrication. The control is by one switch and two levers only. The washing compartment and wringer may be driven together or separately, as desired. The floor space occupied is only 2ft. 10in. by 2ft. 3in.

The "Creda" Kettle Protector.

A patent safety device to prevent the possibility of a kettle boiling dry has recently been put on the market by the Credenda Conduits Company. The device, which can be fitted to all "Creda" kettles and water boilers, automatically cuts off the current when the water



The "Creda" Kettle Protector.

is exhausted. The arrangement of the spring connector makes it a simple matter to disconnect the article from the supply, it only being necessary to press a flat spring, which releases the connector, thus preventing any damage to the flexible cord.

The device, which we illustrate, functions as follows:—A tube containing a special metal is fixed between the heating elements and the bottom of the utensil. From the end of the tube projects a small knob, which is allowed to come forward and upward as soon as the article reaches a certain temperature. The sockets of the connector are fitted with spiral springs which are compressed by the terminals on the article, and the connector is prevented from flying off by means of a flat spring, the end of which engages with the protector knob. When the kettle is boiled dry the protector knob releases the connector, and cuts off the current. Immediately the device has functioned it automatically re-sets itself and the article is again ready for use.

The war memorial tablet to the memory of employees of the Westminster Electric Supply Corporation was unveiled on Wednesday, the 12th inst., by the chairman, Capt. E. I. Bax.

A New Line of Motors.

Fig. 1 represents a new line of motors which the London Electric Firm are now manufacturing in sizes from ¼ to 10 h.p., the smaller ones being bi-polar, and the larger machines having 4 poles. The frames are of cast iron with steel poles, and the bearings are ring oiled (except where ball bearings are used). The design and construction are on the most modern lines throughout. One of these machines was coupled to a dynamo of the firm's make, to generate the current supplied to the Pilot House Searchlight, which was such a feature at the recent Shipping, Engineering and Machinery Exhibition at Olympia.

Fig. 1.

In numerous cases where the speed must be reduced for efficien y driving, the firm make worm reduction gears, as shown in Fig. 2. This is a totally enclosed gear, provided with cast-iron oil bath casing. The worm is of special high grade steel, and runs in ball journal bearings, and is also fitted with ball thrusts. The wheel is of phosphor bronze, accurately hobbed. Automatic lubrication is provided, and any reasonable ratio of gear can be given. Many sizes are made.

Fig. 2.

Fig. 3 shows the special flexible coupling made by the Company for coupling dynamos and motors together. Laminated metal links are used to connect the flanges, no perishable materia being employed. It is claimed to be specially suitable for coupling

Fig. 3.

motors, to reduction gear, pumps, blowers, hoists, etc., and is made in a comprehensive range of sizes.

Chinese Notes.

The Civil Governor of Chihli has reported to the Ministry of Agriculture and Commerce that the establishment of the Peitaiho Coastal Hydro Electric Company by Chu Chih-chien will do no harm to the place.

The original Chinese Merchants' Electric Light Company, at Chungking, has been advised by the authorities to purchase new machinery and to take immediate steps to reorganise the company on a more profitable and efficient basis. Preparations are proceeding.

Parliamentary Intelligence.

Electricity (Supply) Bill.

This Bill has now been through the House of Lords and has been read a first time in the House of Commons.

On the Report stage in the Lords, the Earl of Bessborough moved an amendment to Clause 1, providing that when the amount to be borrowed by a joint electricity authority exceeds £100 000 an order by the Electricity Commissioners should be provisional only, and should not have effect until it had been confirmed by Parliament.

Viscount Peel said that the effect of the amendment would be that joint electricity authorities could not borrow at all. They would be bound hand and foot, and so would the Electricity Commissioners, because nothing could be done without going through a course of procedure which would involve tremendous delay. Local authorities at present could borrow millions from the Electricity Commissioners, but if they joined together and wanted to borrow they could not borrow more than £100 000 without going through a most extraordinary elaborate procedure. However, he proposed the following amendment :—" A scheme constituting a joint electricity authority shall fix, with reference to the estimated capital expenditure of the authority, the maximum sum which may be borrowed by the authority, and the authority shall not have power to borrow under this section sums in excess of the amount so specified unless authorised to do so by subsequent special order."

To Clause 15 (Limitation on prices charged) an amendment was made, on the motion of Viscount Peel, providing that if there was a deficiency in revenue in any year, such deficiency should be divided among the members of the joint electricity authority who took supply, and who would pay in accordance with the number of units supplied. Those who did not take a supply of electricity would not be called upon to make good any of the deficiency.

Lord Bessborough withdrew his amendment, and Lord Peel's amendment was agreed to.

Telephone Service.

Sir H. Brittain asked the Postmaster-General (House of Commons, April 11) whether, with a view to popularising the trunk system, he was prepared to give instructions for time to begin to run when communication had been established with the individual required, and not, as at present, when the number asked for had been obtained?

Mr. Kellaway : I regret that I am unable to entertain this proposal, which would involve a considerable increase in the number of trunk lines and operators, and would virtually convert all trunk calls into what are known in the United States as " particular person " calls, where an extra charge of 25 per cent. or 50 per cent. is made for this service.

Sir H. Brittain asked whether the Postmaster-General was aware that in many instances it was impossible for a tenant to obtain a lease for a full period of twelve months; that a telephone contract must be undertaken for the minimum period of one year; and whether he could see his way to modify such a contract in the case of those desiring a telephone service, but whose tenancy did not hold good for that length of time?

Mr. Kellaway : Where service is required for a short period, it can be provided on payment of a proportionate rental plus the cost of providing and recovering the necessary wires and apparatus or at a year's rental, whichever is the less.

Replying to Lieut.-Colonel Willey, in the House of Commons on April 12, Mr. Kellaway said that he understood the system of reversal of trunk telephone charges in the United States was only in connection with " person to person " calls. It had not been practicable as yet to introduce a service of " person to person " calls in this country, but when the numerous trunk lines now in course of construction were completed further consideration would be given to the matter.

Yorkshire Electric Power Bill.

The Yorkshire Electric Power Bill, which provides for alteration in and addition to the capital of the company, passed its third reading in the House of Lords last week.

Institution of Civil Engineers Awards.

The Council of the Institution of Civil Engineers have made the following awards for papers read and discussed during the session 1921-22 :—

Telford Medals to Sir Henry Fowler (Derby), Mr. H. N. Gresley (Doncaster), and Mr. H. F. Parshall (London); a Watt Medal to Mr. William Willox (London); an Indian Premium to Mr. F. G. Royal-Dawson (London); Telford Premiums to Mr. A. W. Rendell (Bournemouth), Mr. W. F. Stanton (Chile), and Mr. A. C. Walsh (Chile).

The awards for papers printed, without discussion, in the " Proceedings " for this session will be announced in the autumn.

The Council have also made the following awards for papers printed, without discussion, in the " Proceedings " for the session 1920-21 :—

A George Stephenson Medal to Mr. J. H. Taylor (Buenos Aires); Telford Premiums to Mr. F. H. Hummel (Belfast), Mr. E. J. Finnan (Belfast), and Mr. Herbert Chatley (China); and a Trevithick Premium to Mr. G. E. Lillie (Reigate).

Legal Intelligence.

Municipal Election Sequel.

An unpaid electricity account for £2 5s. 2d. was responsible for an unusual application by Blackpool Corporation at the local County Court last week.

The Deputy Town Clerk asked that an amount of £2 5s. 2d., for electricity supplied to Mr. James Kay, be allowed to be sent in and paid by the respondent, as provided by the Municipal Elections (Corrupt and Illegal Practices) Act of 1884. Mr. Kay was a candidate at the November municipal election, and his committee room was supplied by the Corporation with electricity, in respect of which the debt was incurred. The Act provided that all expenses incurred by him had to be paid within twenty-one days, but the County Court might, on the application either of the candidate or of a creditor, allow any claim to be sent in or any expenses to be paid after the time limited by the Act. Mr. Kay had paid all his other bills and had made a return to the Town Clerk, but he had omitted to pay or obtain the account for the electricity due to the Corporation. It had, apparently, been done without any intention to evade payment, and he presumed it was forgetfulness.

The application was allowed.

A Telegraphist's War Bonus.

Last week the Court of Appeal (Lords Justices Bankes and Scrutton, Lord Justice Atkin dissenting) reversed the decision of Mr. Justice Darling in favour of a telegraphist (Mr. Sutton), who brought a test action against the Crown by way of petition of right. The suppliant, relying on a document issued by the Postmaster-General in 1914, left the Post Office for military service. The document stated that postal servants who entered the Army would be allowed " full civil pay in addition to military pay." During the absence of the suppliant bonuses were given to those of the Post Office staff who remained at home, and he claimed the amount of these bonuses. In the court below the suppliant succeeded, but the Court of Appeal reversed the decision by a majority.

American Wireless Patent Litigation.

The United States Circuit Court of Appeals for the Second Circuit has given judgment in the appeal of the De Forest Radio Telephone & Telegraph Company against the decision of Judge Mayer, of the United States District Court for the Southern District of New York, in the action brought by Major E. H. Armstrong against the De Forest Company for the alleged infringement of his patent, No. 1 113 149, for a wireless receiving system. The facts were given in our issue of August 19, 1921, and the present judgment, which affirms the earlier decision, awards to Major Armstrong the credit of having invented the Feed-back or Regenerative-valve Circuit as early as January, 1913.

Funeral of Sir John Benn.

The funeral of Sir John Benn, Bart., head of the firm of Benn Brothers, took place at Limpsfield, Surrey, last Thursday. The first portion of the service was held in Oxted Congregational Chapel, and was conducted by the Rev. Bernard J. Snell, of Brixton Independent Church, and the Rev. Wilton Rix, the pastor at Oxted. In addition to the chief mourners, who included Lady Benn, among those present were Sir Ernest Clarke, Sir Arthur and Lady Spurgeon, the Rector of Oxted, and several representatives of the editorial, publishing, and commercial departments of Benn Brothers, six of whom acted as pall-bearers. Mr. Gillespie, who was at the organ, played " O Rest in the Lord " and Schumann's " Dream " as voluntaries, and as the cortège entered the church " I know that my Redeemer Liveth," from Handel's " Messiah," while at the close he rendered " The Hallelujah Chorus."

At the memorial service at Christ Church, Westminster Bridge-road, London, a large congregation was present including :—The Marquess of Lincolnshire, Lord Riddell, Sir Godfrey Baring, Sir Stephen Collins, Sir Lulham Pound, Sir W. Lancaster, Sir Willoughby and Lady Dickinson, Sir Arthur Roberts, Sir W. Collins, Sir Clement Kinloch-Cooke, Lady Beachcroft (Sir Melvill Beachcroft was unable to be present through indisposition), Mr. and Mrs. Pickstone, Mr. C. W. Bowerman, Mr. John Burns, Mr. G. H. Hume, Mr. St. John Morrow, Mr. W. C. Copperthwaite, Mr. G. W. Humphreys, Mr. J. Rolls Hoare, Mr. and Mrs. J. Benson, Mr. Edward Rice (representing the Kennington Conservative Association), Mr. John Ames, Dr. Scott Lidgett, Captain Albert Larking (secretary of the Early Closing Association), the Rev. Stewart Headlam, Mr. Seth Howard, Mr. Frank Atkins, Mr. J. C. Knight, Mr. A. P. Comyns, Mr. H. J. Greenwood, Dr. and Mrs. Chapple, Captain Swinton, Mr. H. D. Smith, Mr. John Osborne, Mr. G. Mitchell, Mr. H. B. Knight Chorley, the Rev. R. H. Hutchinson, Mr. Arthur Warne Browne, Mr. F. R. Anderton (chairman of the London County Council), and many members of the Council.

The service, at which the Rev. J. D. Jones, the Rev. F. B. Meyer, and the Rev. W. C. Poole officiated, was choral, and included the hymns " O God, our help in ages past," " Praise, my soul, the King of Heaven," and " For all the Saints." Handel's " Hallelujah Chorus " was also rendered, and an address was given by the Rev. J. D. Jones.

The King and Queen sent the following message to Lady Benn from Windsor Castle : " The King and Queen are grieved to hear of the irreparable loss which you have sustained, and desire me to offer you their heartfelt sympathy in your sorrow.—Private Secretary."

Electricity Supply.

The cost of the administration of the Electricity Commissioners' Department for the year ending March 31 was approximately £44 000.

The National Electric Supply Company has been formally taken over by Preston Corporation, who now own every public service except the gas undertaking.

Salford Town Council have sanctioned the renewal of an agreement with the Manchester Corporation to supply a certain amount of electricity in bulk during the next two years.

The electricity supply works built by the Portrush Urban Council were opened on the 13th inst. by Mrs. Kelly, wife of Mr. Andrew Kelly, chairman of the Urban Council. About £17 000 has been expended on the scheme, and the majority of the business and private houses have their connections.

Considerable discussion took place at the last meeting of Reading Town Council on the proposed repairs to the electric lighting system at the Berks Mental Hospital, for which the Council is called upon to contribute over £1 000. The Finance Committee recommended payment of the sum, but the Council referred the matter back for further consideration and report.

Glasgow Electricity and Tramways Departments are in favour of a project to generate electricity at the proposed new refuse destructor works for the south side of the city, and recommend that, if the plan is carried out, their departments take the supply at not less than the then existing cost of production of electricity to these departments.

A. & R. Appleton, flour millers and corn merchants, Hull, have intimated to the Electricity Committee that owing to the high charges for electricity they are placed at a great disadvantage in competing with millers of York, Leeds, Sheffield, Middlesbrough, &c., and that unless this unsatisfactory state of affairs can be remedied they will be compelled to change over to steam or gas, or to transfer their provender plant to Leeds.

The Irish Society have refused to continue negotiations in regard to proposals put forward by the Coleraine Urban Council to rent the water power at the Cutts, on the River Bann, for the purpose of generating electricity for the lighting of the town, and also proposals to give a reasonable indemnity against damage to the fisheries. The society state that, having consulted the lessees of the fisheries, the loss so caused to the salmon fishing would be considerable.

Burnley Electricity Committee have decided to support Newport Corporation in their effort to secure an alteration in the basis upon which salaries are calculated in the E.P.E.A. schedule from that of "plant capacity" to "output," and to effect a re-grading of the basic rates with the object of obtaining a material reduction therein. The electrical engineer (Mr. J. E. Starkie) reported that a second reduction of salaries took effect from April 1, whilst workmen suffered a reduction of 1d. per hour.

At a meeting of Sheffield Electric Supply Committee the general manager of the Electricity Department (Mr. S. E. Fedden) reported that the accumulated profits realised in the installation and motor department, working under "The Sheffield Corporaion Act, 1912," after paying all charges, including interest and sinking fund and income tax, amounted to £32 010, and that year by year these trading profits had been carried to the general appropriation account of the electric supply department. It was resolved "That a sum of £30 000 of this amount be transferred to the relief of the rates."

Glasgow Electricity Committee recommend that, failing to obtain more satisfactory terms, the Corporation should take steps to oppose the resolutions in the House of Commons and the House of Lords approving the Renfrew and District Electricity Special Order, 1922, with a view to the modification of the proposed area of supply. Under one of the proposals the Corporation would be permitted to supply electricity for domestic and shop lighting and heating (but for no other purposes) in Cardonald and Hillington, including the Corporation's housing scheme at Cardonald so far as south of the Glasgow and Paisley Joint Railway, on condition that no cables or wires of a working pressure exceeding 550 V are laid in, through, or over the area described in the Order.

New Schemes and Mains Extensions.

Shrewsbury Town Council have decided to increase the plant at the electricity works by the introduction of oil engines at a cost of £15 000.

Dundalk Urban Council has asked the Irish Minister of Economics to sanction a loan of £18 000 to extend the municipal electrical works.

Application is being made by Thos. Hy. Thompson to the Electricity Commissioners for a Special Order authorising him to generate and supply electricity in Budleigh Salterton (Devon).

In reply to an inquiry from Hazel Grove and Bramhall Urban Council, Stockton Corporation have intimated their willingness to furnish a supply of electricity in bulk for distribution by the Council.

Hemel Hempstead Urban Council has accepted the terms submitted by Watford Urban Council for a supply of electricity. Watford is to apply for a Special Order, under which the Corporation will have the option of purchasing after twenty-one, twenty-eight and thirty-five years, and afterwards at the end of each ten years. The maximum charge to be inserted in the Order is 9d. per unit, but as to actual charges, consumers in the borough are to pay during the first ten years 12½ per cent. above the prices at Watford, and during the next eleven years 5 per cent. above.

Portsmouth Town Council has decided to apply for a Special Order to extend the area of supply to the Havant Urban and Rural Councils and the Warblington Rural District. The estimated cost is £15 800, and it is proposed that the charge to consumers in the new area shall be 2d. per unit above that at Portsmouth for lighting and ½d. above for power.

Alteration of Charges.

A reduction from 7d. to 6d. per unit for lighting and from 2·1d. to 1¾d. for power has been made by Battersea Council in the charges for electricity, the reduction to take effect from the March meter readings.

As from the June meter readings electricity charges at Dewsbury are to be reduced from 7¾d. to 7¼d. per unit to lighting consumers, and from 120 to 100 per cent. over pre-war rates to power consumers on the maximum demand system.

St. Helens (Lancs) Electricity Committee have reduced, as from the 1st inst., the charges for electricity to ordinary consumers for lighting, power and heating from 80 to 60 per cent. above the pre-war rates.

Worcester Electricity Department have decided to allow a discount of 10 per cent. from all electricity accounts (including the rateable charge under the Norwich system) which are paid before the last day of the month on which the accounts are rendered, except the accounts for supplies in bulk rate terms, which include coal and labour clauses, and accounts for public lighting.

Southampton Electricity Department announces considerable reductions in charges for electricity as from the 1st inst. The lighting rate has been reduced from 8d. to 6d. per unit; heating and cooking from 2d. to 1½d. per unit; power, the old sliding scale of 6½d. to 1¾d., reduced to 2½d. sliding scale to 1¾d. Premises supplied with current at the heating and cooking rate of 1½d. per unit must have a lighting installation of not less than six independent points. No rental is charged for the extra meter required for the heating and cooking supply. With regard to power supplies, it is proposed that when the total amount, as calculated on the basis of the sliding scale, is more than would have been due had the consumption been greater per H.P. installed, the amount shall be calculated at the next lower rate.

Electric Traction.

The Minister of Transport has made the Doncaster Corporation Light Railways (Extensions) Order, 1922.

It is stated that the Birmingham Corporation Tramways Committee is losing £800 per week on the 1d. short-stage fares.

St. Helens Tramways Committee proposes to make application for a loan of £40 000 for tramway purposes. In percentage of working costs to revenue, St. Helens works out, with one exception, the lowest in the country.

Wolverhampton Town Council have adopted the recommendation of the Tramways Committee to reduce the minimum ordinary tram fare from 2d. to 1½d. It is estimated that this reduction will result in a deficit of £3 562, but it is hoped that reductions in costs may balance the account.

The Minister of Transport has extended the period allowed by the Western Valleys (Mon.) Railless Electric Traction Act, Oct., 1913, for the completion of trolley vehicle equipment for one year from Feb. 15, 1922; and the period allowed by the Western Valleys (Mon.) Railless Electric Traction (Extension) Order, 1914, for similar work, for one year from July 8, 1922.

Manchester Tramways Committee have received thirty-eight applications for the position of general manager to the tramways, which has become vacant through the resignation of Mr. J. M. McElroy. The applicants have now been reduced to three: Mr. E. S. Rayner, general manager of the Hull Tramways; Mr. J. S. D. Moffet, general manager of Belfast Tramways; and Mr. H. Mattinson, the chief civil engineer to the Manchester Corporation Tramways. These three are to attend the committee meeting on April 25, when the final selection will be made.

In a recent letter to the "Scotsman," "D. R. P." gives some particulars of the official trial trip last month by an electric express train of ten carriages, or 300 tons, from Genoa to Turin and Modane (Mount Cenis route). Over the section from Genoa to Turin, 104 miles, electric trains have been regularly run for more than a year, but it is only recently that the electrification and the supply of hydro-electric power have been extended to the Turin and Modane section (64 miles). Owing to the heavy gradients, up to 1 in 70, on some of the sections of both lines, steam-propelled trains have often necessitated the use of two engines, but the electric trip was accomplished by a single locomotive at the high mean speed of 60 miles an hour over the whole distance of 170 miles. This is, so far, the longest electric main line in Europe. With the regular running of electric trains, the Mount Cenis route will, at least on the Italian side, beat its Simplon rival by something like an hour, and the saving of time will be further extended to the line from Genoa to Spezia and Pisa (for Florence and Rome) when, six months hence, the electrification of that section will also be completed.

Personal and Appointments.

Dr. F. Johnson has been elected chairman of the Birmingham section of the Institute of Metals for the ensuing year.

The Earl of Crawford has been appointed Minister of Transport, without salary, as well as First Commissioner of Works.

Mr. Charles Collinge, permanent way superintendent of Coventry Corporation Tramways, who is leaving for Rochdale, has been presented by the staff with a suit case.

Swindon Town Council has referred back to the Finance Committee for reconsideration a recommendation to reduce the salary of the electrical engineer, Mr. A. Nicklin, from £500 to £475 per year, and that of Mr. T. Medcalf, manager and secretary of the tramways, from £520 to £494.

Business Items, &c.

Gillespie & Beales announce a considerable reduction in the price of the models A, B, C, and D of the "Nilfisk" electric suction cleaner.

The Solidite Manufacturing Company has been formed to take over the business of the Improved Solidite Company, Ltd., of Wandsworth. Large, up-to-date premises have been acquired at Mitcham, which will enable the company to cope more easily with the orders. All correspondence should be sent to the head office of the company, 28, John-street, Bedford-row, London, W.C. 1.

Mr. H. E. Barringer has been appointed manager of the Cardiff office of Simplex Conduits, Ltd., in succession to Mr. J. Entwistle, who was recently appointed manager of the Newcastle and District branch of the company. Mr. Barranger has been connected with the company's Bristol depot for a considerable time, after twenty-one years' previous experience at the head office and works.

Institution Notes.

The annual general meeting of the Electrical Trades Benevolent Institution will be held at the offices of the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London, on Monday, April 24, at 2.30 p.m.

The Paper to be given before the East Midland Sub-Centre of the Institution of Electrical Engineers by Mr. R. J. Mitchell, on "Electric Vehicles," has been postponed from the 18th to the 25th inst., when it will take place at Loughborough College at 6.45 p.m.

The Institute of Physics, of which Sir J. J. Thomson is president, is arranging a course of public lectures with a view to indicating the growing importance and place which physics now hold in industry and manufacture. The first of the lectures, "Physics and Engineering Science," will be delivered by Prof. A. Barr, of Glasgow, on Wednesday, April 26, at 8 p.m., in the Hall of the Institution of Civil Engineers, Westminster, London.

The eighth meeting of the 1921-2 session of the South Midland Centre of the Institution of Electrical Engineers was held at the University, Edmund-street, Birmingham, on the 5th inst., when Dr. C. C. Garrard gave a lecture and showed cinematograph films of the effect of very large currents and heavy short circuits on oil switches, current transformers, potential transformer fuses, &c. Mr. F. Gill showed three reels on "Telephone Inventors" and two on "The Audion." The meeting was very successful, some 250 members and friends being present.

Trade Inquiries.

A loan of Gld.2 400 000 (divided into 2 400 7 per cent. bonds of Gld.1 000 each) is being raised by the Oost-Java Stoomtram Maatschappij (Dutch East Indies) for the purpose of completing the electrification of their lines at Sourabaya. A double track will be laid down with a total length of about 21 kilometres. (Reference, Department of Overseas Trade 771/15/F.G./P.N.)

A firm of manufacturers' agents in Winnipeg desire to obtain the representation of United Kingdom manufacturers of electrical household appliances, automobile accessories, &c., on a commission basis, for Western Canada (Fort William, Ontario, to Victoria, British Columbia). Particulars may be obtained from the Department of Overseas Trade. (Ref. No. 100.)

A consulting mechanical and electrical engineer in Vancouver, British Columbia, who for some years acted as chief engineer to a large colliery company, and has a fairly extensive connection with the coal mining industry in British Columbia, desires to obtain catalogues and prices, particulars and literature on the latest practice in the utilisation of the latest type of coal mining machinery and equipment, coal cutters, electrical switchgear, pumps and small motors, with a view to representing suitable United Kingdom manufacturers, on a commission basis. Particulars from the Department of Overseas Trade. (Ref. No. 405.)

Palmers' Shipbuilding and Iron Company recently accepted the tender of Sir John Jackson, Ltd., for the construction of a dry dock at Swansea in connection with the large ship repairing and engineering works they are establishing. This is the first of two parallel docks which the company intend to construct on the south side of the King's Dock at Swansea, and powerful electrically-driven centrifugal pumps are to be installed for emptying the dock.

Telegraph and Telephone Notes.

A new telephone exchange was opened in the Liverpool district last week. This exchange will be known as Willaston (Birkenhead), and will serve a portion of the existing Bromborough, Hooton, and Neston exchange areas.

In view of the complaints of delays in the transmission of Conference news from Genoa, the Italian Telegraph Administration states that the Genoa telegraph offices despatched on April 10 telegrams containing 210 000 words. On the same day the outgoing telephone calls from Genoa to other Italian towns showed a total of 108 hours, and to towns abroad a total of 22 hours, equivalent to 2 600 conversations of three minutes each.

The London Telephone Advisory Committee passed a resolution last week commending the report of the Select Committee, and urging that prompt effect be given to the report as a whole, and especially to the portions relating to the reduction in charges, the separation of the administration of telephones and telegraphs from mails, the division of the country into separately administered districts, and the securing of better co-ordination throughout the department.

Wireless Notes.

The International Wireless Conference, which opened at Cannes last month, has been transferred to Paris.

A new high-speed commercial wireless service between Berne (Switzerland) and England was inaugurated last week.

It is reported that the German Wireless Transatlantic Company is increasing its capital by 30 000 000 marks, which are to be used for the extension of the stations at Nauen and Eilvese.

The Vancouver correspondent of the "Times Trade Supplement" states that the three daily newspapers of that city have each installed a high-power wireless sending apparatus, by means of which every isolated camp and farm is being brought into touch with the happenings of the outside world. Statistics recently published in the United States show that, whereas five months ago there were less than 50 000 receiving outfits in the whole of that country, and 40 000 of these within 100 miles of New York, to-day there are at least 700 000 of them, and the demand continues to be so great that the factories cannot cope with it. There are thirty-five broadcasting stations in eighteen different States in the Union.

At a conference last week of airway managers and pilots to draw up rules to prevent a recurrence of such an air collision as that which took place over Northern France on April 7, the following, among other, resolutions were passed :—That every commercial aeroplane must be equipped with wireless telephones; that additional ground wireless and weather reporting stations should be established at Poix and Noailles on the French section of the London-Paris airway; that the terminal air stations of Croydon and Le Bourget should now be in constant communication with each other by wireless telephone as well as by ordinary wireless; that the question of "interfering" with wireless telephony by the powerful Eiffel Tower wireless station should now be investigated; that the ground wireless station at St. Inglevert, on the French coast, which was destroyed by fire recently, should now be replaced.

Exhibition Notes.

A sample fair will be opened in Padua next June. At last year's fair 2 000 Italian firms exhibited and 500 foreign, the greater number of the foreign firms being German. This year the fair will occupy an area of 1 700 000 sq. ft., and there will be a special exhibition of scientific instruments, particularly of electrical instruments, electro-magnets, electro-meters, electric ovens, and wireless telegraphic and wireless telephonic equipment.

Under the auspices of the British World Trade Expedition, the 9 000-ton steamship "British Trade" will sail in June from the Port of London on a cruise round the world with an exhibition of representative British manufactures and industries. It was originally intended that this ship should leave London on May 1; but the engineering dispute caused a postponement of the date of sailing, and it has not yet been definitely fixed. The cruise will occupy 267 days, of which 119 will be exhibition days at various ports, including Rio de Janeiro, Montevideo, Buenos Aires, and the chief ports in South Africa, Australia, Tasmania, the South Sea Islands, Japan, the Straits Settlements, India, Egypt, and the Mediterranean. It is hoped that upwards of 150 British firms will be represented in the ship, which will contain every convenience for carrying on business. Cinematograph films depicting exhibitors' works and specialities will be shown at every port of call.

The accounts of King's Lynn Electricity Department for the year ending March 31, 1921, show a gross profit of £3 700. After allowing for interest on loans (£1 227), repayment of capital (£2 017), income tax (£555), and bad debts (£7), a deficit of £106 remains. Capital expended during the year amounted to £23 703, bringing the total capital expenditure to £84 202. The units sold numbered 882 314, against 786 201 in 1920; maximum demand, 736 kW (586 kW); load factor, 13·68 per cent. (15·32 per cent.); private connections, 1 144 (1 087). The total inclusive cost per B.T. unit was 4·55d. (3·84d.), and the average price obtained 4·06d. (3·89d.).

Foreign Notes.

Calcutta Corporation have approved of the proposed expenditure of R300 000 (£200 000) for eight electric lorries.

The Niagara Falls Power Company has been allowed by the Federal Power Commission to amend its plans so as to enable it to erect three hydro-electric units of 70 000 h.p. each and one forebay, instead of five units of 37 500 h.p. each and two forebays as originally proposed.

The volume of German trade with China continues to increase, and the value of machinery imports into Shanghai alone in 1921 compares favourably with imports into the whole of China in 1913 and 1914, while aniline dyes represented a higher value than the whole of Germany's trade in pre-war days.

For the purpose of scientific research and medical uses, the Czecho-Slovakian Government proposes to reserve to itself the sole right of exploiting the radio-active resources of the Republic. Since 1919 the mines at Jachymov have produced 6·5 grammes of radium, which is said to be the purest in the world.

According to a correspondent there is a growing demand for machinery and electrical supplies in Manchuria. The horse tramways in Mukden are to be converted to electric traction, Messrs. Okura & Company furnishing the capital. Orders have been placed in Germany for electrical machinery for the Patahao Mines, near Hulutao Harbour, and a telephone service between Mukden and Tientsin is being contemplated.

President Harding is stated to be one of the most enthusiastic of the American wireless enthusiasts. The Navy Department has recently installed a receiving set for him which can use a wavelength of 25 000 metres. Under ordinary conditions the President can hear not only all the stations in the United States, but also those in Hawaii and Panama, although these overseas stations do not send in voice, but in the Morse code.

The Hidroeléctrica Española, the second most important company in Spain, has, the "Engineer" states, nearly completed the construction of its station at Dos Aguas, the junction of the Rivers Jucar and Gabriel, to the south-west of Valencia. This station will give some 100 000 h.p. when completed, and will help to improve the inadequate power and light service of Madrid, where the existing stations are quite insufficient to meet the increased requirements.

The second Annual Electric Vehicle Show, organised by the New York Edison Company, was held from April 3 to 15 inclusive, and is reported to have been highly successful. A number of new cars as well as the oldest "electric" in existence were exhibited. The first week was devoted to road trucks and pleasure vehicles, and during the second industrial trucks and trailers were on view. The storage battery and accessory sections were strongly represented.

A resolution has been introduced into the American House of Representatives calling for an investigation into the charge that the General Electric, the Westinghouse, the American Telephone and Telegraph, and the United Fruit Companies have combined with the Radio Corporation of America for controlling the manufacture and sale of radio equipment. The cross-licensing of patent rights and the combination of the various interests are considered to be a conspiracy in restraint of trade.

Under the Customs Union, which has recently been instituted between the Free City of Danzig and Poland, the former has the right to allow the import of certain quantities of specified goods at rates lower than those prescribed in the Polish Customs Tariff, on condition that goods imported under this provision are imported before Sept. 30. The list includes installation material for electric plant, telegraph, telephone, &c., apparatus, on which the duty is reduced 25 per cent., the maximum quantity to be imported at reduced rates being 40 tons (metric).

The estimated cost of the new steam station, the trunk lines, and feeders required for the National Electric Supply Scheme of Czecho-Slovakia is put at 1 500 000 000 crowns. As already announced, it is proposed to erect capital stations near the coalfields, and later to construct hydro-electric works. The first part of the scheme will take twenty years to carry out, but it is not expected that the water-power development proposals will be completed for fifty years. All the supply undertakings will be linked up, and the trunk lines will transmit three-phase energy at 100 000 V, 50 cycles.

Tramway Rails and Fishplates.

A revised edition of British Standard Specification and Sections for Tramway Rails and Fishplates has been published by the British Engineering Standards Association. The following are some of the more important modifications which have been made:—(1) Separate analyses are given for the manufacture of rails by the Bessemer and open-hearth processes, both acid and basic, a higher minimum carbon content being specified, and in the case of basic rails added silicon has been provided for; (2) the position in the head of the rail from which the drillings and test pieces for the chemical analyses and tensile tests are to be taken is now defined; (3) the minimum tensile strength of the rails has been increased to 45 tons per sq. in.; (4) the falling weight test is required to be made from each cast, the use of crop ends of rails being permitted, and is to be carried out on the British Standard falling weight testing machine, the specification for which is inserted as an appendix; (5) the testing procedure before rejection, both for rails and fishplates, has been set out in detail; and (6) a standard series of short lengths is given. The brand or mark of the Association now indicates only that the rail is of British Standard section.

Miscellaneous.

The death has occurred of Mr. P. A. E. Dowling, Registrar of the College of Science, Dublin.

The late Mr. J. T. Allingham, of the British Mannesman Tube Company, has left estate valued at £6 170.

The late Mr. Hugh Bramwell, chairman of the Treforest Electrical Consumers' Company, has left estate valued at £21 465.

The late Sir Francis Barker, a director of Vickers, Ltd., Canadian Vickers, Ltd., Metropolitan-Vickers Electrical Company, Electric Holdings, Ltd., British Lighting and Ignition Company, Compagnie Electro Mécanique, &c., has left estate valued at £118 801.

At Burnley Quarter Sessions last week, Edwin Growden Langsford, an electrician, was remanded until the next sessions on charges of obtaining money by false pretences. The Recorder said this would give him an opportunity of repaying the money as he had promised and to test his sincerity.

An interesting feature of the special Lauder Performance at the Princes Theatre on April 26 will be the presence of prominent leaders of both organised capital and organised labour. The performance is to be under the personal patronage of H.R.H. the Duke of York, and the proceeds will go to the Industrial Welfare Society, of which he is president.

Thirteen men were injured, seven seriously, by an explosion which occurred in one of the mines of the Viewpark Colliery, Uddingston, near Glasgow, last week. At first the cause was thought to be due to firedamp, but later the belief was current that one of the electric cables of the coal-cutting plant fused and ignited an accumulation of gas.

The Metropolitan Asylums Board, states the "City Press," provides a remarkable instance of the vagaries of tendering. For so straightforward and simple a job as the installation of the electric light at a certain hospital, the prices submitted by contractors ranged, it states, between £943 and £5 600. The latter figure was £3 600 above the one next to it!

The librarian of the R. Istituto Lombardo di Scienze e Lettere of Milan is anxious to find the letters of Alessandro Volta to De Luc, and of any other letters and MSS. of Volta, for the national edition of Volta's works, which is being prepared under the auspices of the Italian Government by a commission attached to the Istituto Lombardo. Information on the subject should be sent to Mr. Paget Toynbee, Fiveways, Burnham, Bucks.

It has been decided to reduce the grade of the Commercial Diplomatic posts at Rome from Commercial Counsellor and Commercial Secretary (Grade II.) to Commercial Secretary (Grade I.) and Commercial Secretary (Grade III.) respectively. The senior post, which was vacant owing to the resignation, which we announced last week, of Sir E. Capel Cure, has been filled by the promotion of Mr. J. H. Henderson, the present Commercial Secretary (Grade II.) at Rome; and the junior post by the transfer of Mr. H. C. A. Carpenter, Commerical Secretary (Grade III.) at Washington.

A case at the Dudley Police Court last week is a good illustration of the damage that can be caused by small boys when tools are left lying about. Two boys, named Aston and Hicks (thirteen years of age), were charged with causing damage at Messrs. Goodyear & Sons' works. The works are connected with the G.W. Railway by a private electric tramway, and a tramcar, which was left on the line, was set in motion by one of the two boys using a loose spanner for switching on the electric current from a switch-box. The tramcar, having been started down an incline, dashed into an embankment and was smashed. The damage was estimated at £1 000. One of the boys was ordered to receive six strokes with a birch-rod and the other was discharged.

The 1922 Year Book and Export Register of the Federation of British Industries has been divided, for easy reference, into four sections. Section I. gives a general survey of the scope and activities of the Federation, the qualification and specific services gained by membership, &c. In Section II. the manufactures and products of F.B.I. firms and Associations are arranged in alphabetical order. Under each heading is given a list of the firms manufacturing the article indicated in the heading. In Section III. all members, whether firms or Associations, are listed together in alphabetical order. After each name is given, in the case of firms (*a*) a brief description of their business, (*b*) head office, works, and cable addresses, and (*c*) names and addresses of agents overseas. In the case of an Association the name and address of the secretary is given, a brief statement of its objects, and, in many cases, a list of members. Section IV. contains 340 pages of members' advertisements. In addition to the advertisements the book contains 454 pages, and is on sale at 25*s.* net.

Owing to the high cost of the Queenstown-Chippawa hydro-electric development and of the consequent higher charges for power by the Ontario Hydro-Electric Commission, the Ontario Legislature have decided to appoint a Royal Commission to conduct a full and impartial investigation into the expenditure and estimates of the Commission, of which Sir Adam Beck has been chairman for many years. About a month ago Colonel Carmichael, Minister without portfolio in the Ontario Cabinet, resigned from the Commission because last year's estimates had been exceeded by over £3 000 000.

Tenders Invited and Accepted.

UNITED KINGDOM.

FALKIRK PARISH COUNCIL. May 1.—Six months' supply of electric lamps, ironmongery, &c., to Blinkbonny Home. Schedules, &c., from the Governor.

GLASGOW ELECTRICITY DEPARTMENT. May 1.—Supply of (1) cables (including small IR cables and flexibles); (2) meters; (3) carbons, for a period of twelve months. Particulars from R. B. Mitchell, Engineer, 75, Waterloo-street, Glasgow.

DOUGLAS (ISLE OF MAN) CORPORATION. May 8.—Ten-ton travelling crane, two oil engines, with oil storage tank, cooler and piping, two 210 kW d.c. generators and balancer-booster set, main switchboard and storage battery. Specifications from Messrs. Handcock & Dykes, 11, Victoria-street, London, S.W. 1.

H.M. COMMISSIONERS OF WORKS.—Erection of a telephone repeater station at Taplow, Bucks

ASIA.

DEPARTMENT OF POSTS AND TELEGRAPHS, BANGKOK. June 5.—Telegraph and telephone materials to the value of £10 000. Tender forms can be obtained from the Chief Electrical Engineer, Telephone Exchange, Bangkok.

MANCHESTER Corporation have accepted the tender of Walter Scott, Ltd., for steel girder tramway rails.

KETTERING Corporation have accepted the tender of the Union Cable Company for two feeder cables.

HALIFAX Corporation have accepted the tender of Crompton & Company for a d.c. switchboard, £1 665.

LEEDS Corporation have accepted the tender of W. T. Henley's Telegraph Works Company for cable, £1 187.

CANNOCK Urban Council has accepted the tender of Raybould & Ancott, Darlaston, for wiring the Council offices at £98.

MANCHESTER Corporation have accepted the tender of Ferguson, Pailin, Ltd., for a 200 A 6 000 V oil switch for Stuart-street station.

PORTSMOUTH Town Council has accepted the tender of Babcock & Wilcox for a Green's economiser for the electricity works, at £3 726.

BIRKENHEAD Corporation have accepted the tender of Holden & Brooke for electrically-driven turbo pumps at Flaybrick Hill and Tranmere reservoirs, £1 896.

DUBLIN Corporation have accepted the tender of the British Electric Transformer Company for twelve months' supply of transformers, estimated at £7 000.

GLASGOW Coporation have accepted the tenders of the British Thomson-Houston Company for converting plant, £11 012, and switchgear, £1 414; and Johnston, Park & Company for electrical work in the municipal buildings extension.

MARYLEBONE (London) Council have accepted the following tenders: British Electric Transformer Company, transformers, £3 537: Ferguson, Pailin, Ltd., switchgear, £2 688.

BRADFORD Corporation have accepted the tenders of Thompson & Company for 500 5-A s.p. meters, and Jessop & Baydell for wiring and fitting the Electricity Department's new offices and showrooms.

EDINBURGH Corporation have accepted the tender of Dorman, Long & Company for tramway rails and fishplates, £1 527 10s., and Craven's Railway Carriage & Wagon Company for tramcar top covers, £4 300.

BARROW Corporation have accepted the tenders of the Metropolitan-Vickers Electrical Company for insulating tape, &c.; British Insulated & Helsby Cables, Ltd., insulating compound; A. P. Lundberg & Sons, pin-plugs; General Electric Company, lampholders, switches, &c.; Edison Swan Electric Company, fuse wire and half-watt and carbon filament lamps; Chamberlain & Harkham, meters; Downes & Davies, casing and capping.

SUNDERLAND Electricity Department have accepted the following tenders:—British Insulated and Helsby Cables Company, 600 yards 0·154 cables; Callender's Cable and Construction Company, 12 service boxes and 5 link boxes; Armstrong, Addison & Company, creosoted redwood capping; Ferguson, Pailin, Ltd., two l.t. switch panels; Cambridge Scientific Instrument Company, temperature and flue-gas recorders; Consolidated Pneumatic Tool Company, electric drilling machine.

The WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, East Pittsburg, Pa., have received contracts, amounting to approximately $250 000, from the Commonwealth Edison Company, of Chicago, and from the Consolidated Gas, Electric Light and Power Company, of Baltimore, for five large booster converters, with transformer and equipment. This company have also been awarded the contract for electrical equipment for a new power-house, to be constructed by the Southern California Edison Company, and to be known as Big Creek, No. 3. The contract gives to the company all switching equipment, both h.t. and l.t., for this station and all h.t. switching equipment at three sub-stations—Magunden, Eagle Rock and Vestal.

EDINBURGH Town Council recently decided, by 30 votes to 19, to accept the tender of Dorman, Long & Company for steel tramway railways and fishplates at £1 527 10s., in preference to the offer of the Equipment & Engineering Company, Ltd., London, at £1 425, the rails to be of German manufacture. A recommendation by the Tramway Committee to accept the tender of Mannesmanrohen Works, Dusseldorf, amounting to £5 436, for one-piece tramway poles was defeated, an amendment by Mr. Gorman to accept the lowest tender for three-piece poles—*viz.*, that of Stewart & Lloyds (Ltd.), Glasgow, being adopted by a majority.

Islington (London) Council have accepted the following tenders:—Chamberlain & Hookham and British Insulated & Helsby Cables, Ltd., meters; British Electric Transformer Company, transformers; Johnson & Phillips, steel transformer tanks; Hackbidge Construction Company, c.i. tanks; General Electric Company, carbons; the British Central Electrical Company, arc lamp globes; British Insulated & Helsby Cables, Ltd., h.t. insulated cables; Enfield Ediswan Cable Works, Ltd., l.t. paper-insulated cables and h.t. and l.t. rubber-insulated cables; Callenders Cable & Construction Company, joint and cable boxes, h.t. fuse and l.t. service boxes and dividing boxes; British Insulated & Helsby Cables, dividing boxes; Lucy & Company and Johnson & Phillips, fuse boxes; W. Lucy & Company and H. Hughes & Son, l.t. service boxes; Dussek Bitumen Company; W. T. Henley's Telegraph Works Company and India Rubber Gutta Percha & Telegraph Works Company, compounds, tapes, &c.; British Insulated & Helsby Cables, carbon and m.f. lamps; Edison Swan Electric Company and L. Andrews & Company, wiring accessories.

MANCHESTER Corporation have accepted the following tenders: Dyer & Young, commutator segments, &c.; Metropolitan-Vickers Electrical Company, commutator segments, coils, spindles, brushes, brake shoes, motor and controller parts, &c.; Manchester Armature Repair Company, coils; P. R. Jackson & Company, coils; British Thomson-Houston Company, pressure-arms and tension-springs, motor and controller parts, &c.; L. Andrew & Company, fuller board mica bushings, tapes, &c.; Fairless Engineering & Supplies Company, controller fingers, &c.; S. Gratrix, Jun., & Brother, connectors, cells, shades, muranese glass, &c.; General Electric Company, lamps, switches, &c.; Drake & Gorham (Wholesale), lamps and filaments; Commercial Electric Company, lamps; Edison Swan Electric Company, cells; A. Wiseman, Ltd., overhead equipment and insulating material; Tramway Supplies, Ltd., trolley-wheel bushes; R. W. Reeves, Ltd., electro-mechanical brake parts; W. T. Glover & Company, power and lighting cables; F. Smith & Company, Inc., copper cable, string and wire; F. Smith & Company, Ltd., steel tinned wire; Edgar Allen & Company, points and tongues, &c.; Quasi Arc Company & Alloy Welding Processes, electrodes; Chamberlain & Haskham, car meters; English Electric Company, controller parts.

Openings for Trade in the Netherlands.

The following extracts from the Dutch Press of recent dates may lead to openings for British trade:—

Plans have been drawn up by J. Vrijman, Parkstraat 16, The Hague, for the building of a new laboratory for scientific instruments at Groningen. Work will begin next year.

The Town Council of Deventer have decided to lay an electric cable along the left bank of the Ijssel.

The managing board of the starch factory, "De Beijenkorf," formerly M. K. Honig, of Koog aan de Zaan, intend adding to their works a new water pump station with electric motors. Work will commence in a few months' time.

The municipal electric power station at Haarlem (address, Harmen Jansweg 131) is to be extended. Estimate Gld.248 000. Work will be begun as soon as possible.

A proposal has been laid before the Town Council of Nijmegen to take the transport of house, street, and factory refuse under their own management, starting with 1923. For this purpose several motor vehicles would have to be purchased.

A loan of Gld.2 400 000 (divided into 2 400 7 per cent. bonds of Gld. 1 000 each) is being raised by the Oost-Java Stoomtram Maatschappij for the purpose of completing the electrification of their lines at Soerabaja. A double track will be laid down, with a total length of about 21 kilometres.

Forty Years Ago.

ELECTRIC LIGHT IN BELFAST.—The Town Council have accepted the offer of Mr. J. H. Greenhill, of Belfast, to light a portion of Castle and Mill Streets with the electric light, free of charge.

ELECTRIC LIGHT IN SHEFFIELD.—We believe that Messrs. Tasker, Sons & Company, of Sheffield, and well known in connection with telephonic work, are about to form a local company for the introduction of the electric light into that town.

CITY AND GUILDS INSTITUTE.—We are glad to find that Mr. J. Perry, M.E., has been elected to the Chair of Mechanical Engineering at the City and Guilds of London Technical College Finsbury, this week. We know of no one more fitted for the position.

ACTION OF ELECTRIC-MAGNETS ON MINERALS.—Experimenting with electro-magnets on various minerals, Professor Doelter has made the interesting observation that the absolute amount of iron present does not determine the degree to which the minerals are attracted, for sulphides and sulphates, containing much iron, are very little attracted, while the attraction of oxides, carbonates, and silicates is strong. This varying amount of attraction, it is pointed out, may be of service in mechanical separation of natural mixtures of ores, purifying ores, &c.—"Nature."

Companies' Meetings, Reports, &c.

The Direct United States Cable Company has declared a final dividend of 4s. per share, less tax, making 4 per cent. for the year ended March 31, 1922.

The Indo-European Telegraph announce a final dividend for the year ended December of £1 2s. 6d. per share (making with interim dividend already paid 7 per cent. for year), free of tax.

Letters of allotment and regret have been posted in respect of the Metropolitan Railway Company issue of £600 000 5 per cent. preference stock, which was enormously over-subscribed, applications having been received for more than £8 000 000.

An extra-ordinary meeting of the Hydro-Electric Power & Metallurgical Company is to be held in Melbourne after the ordinary meeting on April 21, to consider a resolution that the name of the company be changed to Carbide & Electro Products, Ltd.

The report for 1921 of Brolt, Ltd., states that the year's trading has resulted in a loss of £23 808, after providing for depreciation of buildings, plant, and machinery, and making due provision for all bad and doubtful debts. Deducting the surplus of £1 758 brought forward from last year, there is a net deficiency of £22 049 to be carried forward.

The report of the City of Santos Improvements Company for 1921 shows net revenue of £86 958, plus £13 431 brought forward, making £100 389, compared with £120 301 in 1920. The directors have transferred £5 000 to reserve, and, having set aside £6 000 to tramways renewal account, they recommend a final dividend of 3 per cent. on the ordinary shares, making 5 per cent., less tax, for the year, carrying forward £11 519.

The following companies will be struck off the Register of Joint Stock Companies unless cause to the contrary is shown before July 11 next :—Denton Electrical Construction Company, Denton's Foreign Patents, Derby Lamp Works, Electric Timekeepers, Electro Galvanisers, Holmquist Electric Company (1911), Londonderry-Moville Electric Railway Syndicate, Sandbanks Railless Electric Car Company, Swanage Electricity Supply Company, United States Railless Electric Traction Company.

The report of the Shawinigan Water and Power Company for 1921 shows gross earnings of $4 224 046, against $3 943 359 for the previous year, and net revenue of $1 590 813, against $1 609 043. After making usual appropriations and paying a dividend on the common shares of 7 per cent., there is carried forward $155 406. Owing to the depressed industrial conditions of last year the new power development at Shawinigan Falls will not be completed until September.

The Stock Exchange Committee have granted or ordered the following securities to be quoted in the Official List : £823 300 7 per cent. 50-year prior lien A bonds of the Barcelona Traction, Light & Power Company ; 755 780 £1, fully paid, ordinary shares and 650 000 £1, fully paid, 6 per cent. cumulative preference shares of the County of London Electric Supply Company ; and £350 000 6 per cent. guaranteed debentures of the Thames Valley (N.Z.) Electric Power Board.

The report of the Western Union Telegraph Company for 1921 shows gross operating revenues $104 155 112. After deducting operating expenses, including repairs, reserve for depreciation, rent for lease of plants, taxes, &c., $93 959 083, the sum of $10 196 029 remains, plus income from dividends and interest $1 072 962. Interest on bonds absorbs $1 635 183, leaving balance transferred to the surplus account of $9 633 808, which, with $40 685 211 brought in, makes $50 319 019. Dividends paid and declared took $6 982 622, and adjustments of surplus (net) $272 703, leaving surplus at Dec. 31, 1921, $43 063 692.

In accordance with the terms of the trust deed of the Submarine Cables Trust, tenders are invited from the certificate-holders of certificates to be redeemed out of surplus income, accrued to the 15th inst., at a price not to exceed £120 per certificate, the certificate-holder retaining the coupon of reversion attached to any certificate which may thus be redeemed. Certificate-holders desirous of surrendering their certificates on the above-mentioned terms should communicate with the secretary, Mr. Sidney Collett, Electra House, Moorgate, London, E.C. 2, stating the lowest price they are willing to accept.

The Rangoon Electric Tramway and Supply Company recommend a dividend of Rs. 1 per share, tax free, to shareholders in India or Burma on the ordinary shares, making Rs. 1½ for the year. The sum of £30 000 has been placed to reserve for renewals ; £2 927 for depreciation on sundry assets in Rangoon : £7 333 for Indian Income-tax ; £3 359 for Corporation Tax ; £3 641 for employees' provident fund and bonus ; £2 927 for depreciation of sundry assets : £3 224 for loss on exchange and expenses of new issue ; £26 305 for repairs, renewals, and maintenance, leaving £12 969 to be carried forward. It is proposed to increase capital to £800 000.

The total receipts of Rothesay Tramways Company for 1921 amounted to £22 335. After providing for all expenses chargeable to revenue, including £1 920 for debenture and other interest, payment to local authorities amounting to £270, and providing £2 310 for the renewals fund, there is, with £1 609 brought forward, a balance of £7 301, which the directors propose to dispose of as follows : reserve, £2 000 ; dividend of 5 per cent. on the preference shares, £500 ; dividend of 4 per cent. on the ordinary shares for the year, £3 270 ; leaving £1 530 to be carried forward. The dividend on the ordinary shares for the preceding year was 3 per cent.

The accounts of the City Electric Light Company, Ltd., of Brisbane, for the year ended Jan. 31 last show, after making addition to the sinking fund and renewal and contingencies account, and an amount to the employees' provident fund, a credit balance £77 359, which, with the balance brought forward, makes £77 541. Out of this year's profits the directors paid an interim dividend with dividend duty in September last amounting to £34 506, and a further dividend on March 15 of 3 per cent. on the 6 per cent. preference shares, 3½ per cent. on the 7 per cent. preference shares, and 5 per cent. on the ordinary shares, in proportion to the amount paid thereon, free of tax, leaving a balance of £109 10s. to be carried forward, against £181 last year.

The accounts of Wycombe (Borough) Electric Light and Power Company for the year ended Dec. 31 last show, including balance from contracting business, a gross profit of £17 004, compared with £16 993 in 1920, and after paying interest on debentures, loan, and outstanding accounts, and adding the amount brought forward from last year, there remains a balance of £14 276 to be dealt with. The directors recommend that a dividend of 10 per cent. be paid for the year, which will absorb £5 000, that £5 000 be placed to the renewal reserve fund and £4 000 to general reserve fund, leaving a balance of £276 to be carried forward. To meet the increasing demand for electricity, additional generating plant is now being installed at a cost of about £15 000. To provide the necessary capital for this extension it is proposed to issue 3 000 £5 cumulative 10 per cent. preference shares. The connections during the year show an increase of 142 kW.

New Companies.

J. B. Bower & Company.

J. B. Bower & Company, Ltd. (180 937). Private company. Registered April 5. Capital, £10 000 in £1 shares. Manufacturers of and dealers in electrical apparatus, machines, accessories, &c., at Wimbledon or elsewhere, and to acquire the business carried on by the Wimbledon Electrical Company, Ltd. First directors : J. P. Wallis Trevone, J. B. Bower (both directors of Wimbledon Electrical Company, Ltd.), and O. O. Dale. Registered office : 15, Kingston-road, Wimbledon, S.W. 19.

Electric House Cafes.

Electric House Cafés, Ltd. (181 072). Private company. Reg. April 11. Capital, £3 000 in £1 shares. To carry on in the United Kingdom shops, cafés, &c. Subscribers : H. Wintle, A. C. MacWhirter, W. A. Chamen, J. H. P. Herthow, T. E. Alger, C. T. Allen, and H. T. Ellis. Solicitor : R. W. Nicholas, 31, Queen-street, Cardiff.

Electricity Concessions (Ireland).

Electricity Concessions (Ireland), Ltd. Private company. Registered in Dublin, April 8. Capital, £1 919 in 380 shares of £5 each and 380 shares of 1s. To acquire the business of electrical engineers and contractors carried on by A. D. Brown, at Municipal Buildings, Blackrock, as the "Irish Overseas Direct Trading & Engineers Association." First directors : A. Brown and D. J. Byrne. Secretary : G. J. Crowe. Registered office : Municipal Buildings, Blackrock, co. Dublin.

Haywards Heath & District Electrie Supply.

Haywards Heath & District Electric Supply Company, Ltd. (181 143). Registered April 13. Capital, £30 000 in £1 shares. To acquire from E. A. Bridge, H. Dearden, H. Finch, T. White and E. Prior, with the consent of and on such terms and conditions as may be approved by the Electricity Commissioners, the undertaking authorised by the Haywards Heath & District Electricity Special Order, 1922, and to carry on the business of suppliers of electricity in all its branches. First directors : E. A. Bridge, H. Dearden, H. Finch, T. White and E. Prior. Registered office : Hornbeam, Perrymount-road, Haywards Heath, Sussex.

Lighting & Power Finance Corporation.

Lighting & Power Finance Corporation, Ltd. (181 031). Private company. Registered April 8. Capital, £2 000 in 1 800 preference shares of £1 each and 4 000 ordinary shares of 1s. each. To carry on any trade connected with electric lighting, electrical distribution for light, heat and power electrical and general engineering, building and contracting, for the supply and construction of electrical and engineering works, &c. Subscribers : R. E. Lenon and W. C. Green. Registered office : 20, Abchurch-lane, E.C.

Plant and Supplies.

Plant and Supplies, Ltd. (181 109). Private company. Reg. April 12. Capital, £4 000 in £1 shares. Electrical and mechanical engineers, dealers in electrical and mechanical plant and engineering supplies, &c. Subscribers : A. P. Pope and J. P. Southwell. Registered office : 12 and 13, Henrietta-street, W.C. 2.

Tele-Photography.

According to "The Times," M. Edouard Belin has communicated to the French Academy of Sciences a description of the modifications he has recently made in his process of transmitting photographs by electrical means. The account states that the photograph to be transmitted is printed on gelatine impregnated with bichromate, the film being mounted on a revolving metal cylinder. A stylus, which is connected to a special microphone, records the variations in the thickness of the gelatine print and causes corresponding variations in the resistance of the electrical circuit. At the receiving end a minute spot of light from the special arc lamp is focussed on to the mirror of a Blondel oscillograph. Variations in intensity are produced by using a glass screen with a scale ranging from complete opacity to complete transparency, and the variations are focussed on to a sensitive film, which moves in complete harmony with the gelatine print in the transmitter.

COMMERCIAL INTELLIGENCE.

County Court Judgments.

[NOTE.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

ELLARD-STYLES & COMPANY, LTD., 287, Upper-street, Islington, electrical engineers. £21 15s. 5d. and £10 12s. 6d. Feb. 16.

GILL & WHITE, 26, Hardwick-street, Buxton, electricians. £11 9s. 4d. Feb. 21.

KIRBY, Mr. R. J., 62, Oxford-street, W., electrical engineer. £23 11s. 10d. Feb. 17.

SOUTH WALES ELECTRIC WELDING COMPANY, King's Dock, Swansea, electric welders. £30 0s. 6d. Feb. 4.

WENMAN, Harry Orlando, Electrical Works, Ludlow, electrical engineer. £31 17s. 9d. Feb. 7.

Deeds of Arrangement.

TUCKER, Spencer John (trading as TUCKER & BATESON), 55, Berners-street, Oxford-street, electrical engineer. Filed, April 13. Trustee, T. L. Summers, 64, Victoria-street, A.A. Secured creditors, £135; liabilities unsecured, £1 157; assets, less secured claims, £253.

WEBSTER, Ernest Walter, and WEBSTER, Walter George Frederick, trading at 48-50, Rendezvous-street, and the Harbour, Folkestone, as WEBSTER & SON, automobile and electrical engineers. Filed, April 7. Trustee, W. J. Bennett, 173, Fleet-street, E.C. Liabilities unsecured, £4 610; assets, less secured claims, £3 971.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Company Winding-up.

BISHOPS CASTLE ELECTRIC LIGHT & POWER COMPANY, LTD. A petition for winding-up has been presented by the Premier Accumulator Company (1921), Ltd., of Cattle Market-road, Northampton, and is to be heard at the County Court, Leominster, Hereford, on May 8 at 10 a.m.

Companies Winding-up Voluntarily.

B E. COMPANY (OF LONDON AND BIRMINGHAM), LTD. F. Rowland, 70, Queen Victoria-street, London, appointed liquidator. Meeting of creditors at the Cannon-street Hotel, Thursday, April 20, at 3 p.m. Particulars of claims to the liquidator by April 20.

EVANS, DEWHURST & COLLEY, LTD. A. Shankland, 82, Queen-street, Cardiff, appointed liquidator. Meeting of creditors at 82, Queen-street, Cardiff, Tuesday, April 25, at 3 p.m.

HUBERT D. CARTER (BANGOR), LTD. W. Rowley-Redwood, Strand Buildings, Abergele-road, Colwyn Bay, appointed liquidator. Meeting of creditors at the offices of A. McIntyre & Company, Strand Buildings, Colywn Bay, at 12 noon, Friday, April 21. Particulars of claims to the liquidator by May 8.

NATIONAL ELECTRIC SUPPLY COMPANY, LTD. W. H. Ainsworth, 11, Winckley-street, Preston, appointed liquidator. Meeting of creditors at liquidator's office, Tuesday, April 25, at 3 p.m. Note.—This notice is given to comply with the Companies Acts. All creditors have been or will be paid in full.

PORTARLINGTON ELECTRIC LIGHT AND POWER COMPANY (THE), LTD. Michael Crowley, 16, College-green, Dublin, appointed liquidator. Meeting of creditors at liquidator's office, Saturday, April 22, at 11 a.m.

Bankruptcy Information.

COOKSON, Eugene (trading as W. TURNBULL & COMPANY), the Express Magneto Repair Works, Elizabeth-street and Charles-street, Blackpool, electrical, &c., engineer. First meeting, April 20, 10.30 a.m., 13, Winckley-street, Preston. Public examination, April 21, at 3 p.m., Court House, South King-street, Blackpool.

HOLMES, Samuel, Palatine Chambers, Halifax, under the style of HOLMES & COMPANY, electrical contractor. Receiving order, April 11. Debtor's petition. First meeting, April 28, 10.15 a.m., and public examination, May 19, 10.30 a.m., County Court House, Prescott-street, Halifax.

ORMONDE, Frank Sinclair (in co-partnership with another), under the style of the SOHO ELECTRICAL WORKS, at 125, Islington, Liverpool, electrician. Receiving order, April 8. Debtor's petition.

VIVIAN, Albert, 180, Gray's Inn-road, London, W.C., electrical engineer. Receiving order, April 10. Creditor's petition. First meeting, April 26, 12 noon, and public examination, June 20, 11 a.m., Bankruptcy Buildings, Carey-street, London, W.C. 2.

Partnerships Dissolved.

DUNSTER, Cecil George, and BACON, Vincent Edward, under the style of DUNSTER & BACON, 19, North Holmes-road, Canterbury, Kent, electricians, by mutual consent as from April 8, 1922.

FAVELL, John Edward, and MARTIN, Thomas Dawson, electrical merchants, 2, North-street, Newcastle-upon-Tyne, under the style of JOHN E. FAVELL & COMPANY, by mutual consent as from March 29, 1922. Debts received and paid by J. E. Favell, who will continue the business.

MALLIN, Matthew, MALLIN, James, and MALLIN, Luke, electro-platers and polishers, 29 and 30, Raglan-street, Wolverhampton, under the style of THE CROWN PLATING COMPANY, by mutual consent as from April 11, 1922.

WOOD, Lionel, and MEARNS, Henry, under the style of SLEIGH & WOOD, electrical and mechanical engineers, of Consett Chambers, Newcastle-upon-Tyne, as from March 27, 1922.

Edinburgh Gazette.

J. L. BROWN & COMPANY, electrical engineers, 920, Pollokshaws-road, Glasgow (J. L. BROWN, trading as). A petition for sequestration of the estates of this firm and sole partner has been presented at the instance of Johnstone & Gilmour, 606, Eglinton-street, Glasgow.

LIVINGSTONE & MALCOLM, electricians, 7, Canal-street, Coatbridge (JAMES LIVINGSTONE & FRANK MALCOLM, trading as). A petition for sequestration of the estates of this firm and partners has been presented at the instance of the Edison Swan Electric Company, Ltd., 123-125, Queen Victoria-street, London.

Bankruptcy Proceedings.

BENNETT, Charles Godolphin, engineer, 66, Mark-lane, E.C. The affairs of this debtor, who had been interested in an electric switch-holder, and against whom a receiving order was made on Dec. 13 last, came before Mr. Registrar Hope at the London Bankruptcy Court on Wednesday, April 12, on the hearing of his application to approve a composition of 7s. 6d. in the £, which had been accepted by his creditors. The Official Receiver estimated the total liabilities at £1 422, but said that since the date of the receiving order two claims for £104 and £69 had apparently been paid. The assets were estimated by the debtor at £103, and in his (the Official Receiver's) opinion, apart from court fees, a sum of £551 would be required to pay the composition and attendant expenses. In 1906 the debtor began business in partnership at the above address, but later on he carried on business by himself. Since March, 1916, he had been associated with another in experimenting and putting on the market an electric switch-holder, which he had financed to the extent of £2 000. The debtor attributed his insolvency to loss in connection with that project and to lack of capital. He admitted that he was not a professional engineer, but he claimed to have been interested in electrical subjects all his life. He estimated his loss in connection with the switch-holder at £2 847, and admitted that probably if he had not entered into that venture he would not have been insolvent. The Official Receiver reported that the debtor's assets were not of a value equal to 10s. in the £, that he had omitted to keep proper books of account, and that he had contributed to his failure by rash and hazardous speculation. With regard to the proposal, the Official Receiver considered that it was reasonable and calculated to benefit the creditors. The Official Receiver added that the application had stood over from the date it was originally before the Court to enable the debtor to lodge the rest of the money. It was largely a question of a proof of debt for £267, in which the creditor had not included the security that he held. His Honour now made an order approving the composition.

RAWCLIFFE, Frank, trading as FRANK RAWCLIFFE & COMPANY, 8, Nun-street, Newcastle-on-Tyne, electrical engineer. The statement of affairs shows liabilities of £3 866 against assets of £11. At the first meeting of creditors the Official Receiver stated that a limited company had been formed in August, 1921, to take over the liabilities. This company was now in voluntary liquidation, and there had been a suggestion of a payment of 10s. in the £ by means of debentures liquidated every three months. Debtor stated that the whole of the creditors could claim against the limited company and get 10s. in the £. The meeting was adjourned.

The INTERNATIONAL WESTERN ELECTRIC COMPANY reports that 1921 was the best year in its history, and the total sales of the company and its associates amounted to $41 000 000. The associated companies in England and Belgium were operated at full capacity, and the export business compared favourably with that of 1920. The demand for telephone equipment all over the world continues to increase.

Catalogues, Price Lists, &c.

Two illustrated loose-leaf pamphlets are to hand from MELDRUMS, LTD., describing in detail their forced draught furnaces and mechanical stokers.

In No. 7 of the series of TRANSFORMER ABSTRACTS, published by Johnson & Phillips, the question of "Switching-in Current Rushes" is dealt with in detail.

The latest stock list of motors and dynamos of the A.C.E.C. (ATELIERS DE CONSTRUCTIONS ELECTRIQUES DE CHARLEROI), received from the firm's London offices in Victoria-street, shows that the company hold a stock of between 1 100 and 1 200 a.c. and d.c. motors from which immediate delivery can be given. The pamphlet is well illustrated, but it would doubtless add to its value if it were printed in English as well as in French.

The ELECTRIC & ORDNANCE ACCESSORIES COMPANY, of which the proprietors are Vickers, Ltd., are circulating a new abridged catalogue of their porcelain insulators. Numerous designs of h.t. bushings, bus-bar insulators, telegraph and telephone insulators, cleats, threaded tubes, leading-in tubes, h.v. ceiling roses, &c., are illustrated, the firm's patent "fireite" heat-resisting and insulating material being employed in their manufacture.

No better way of showing the wide range of trucks manufacured by the firm of H. C. SLINGSBY could have been chosen than the sheet recently issued, which measures 2 ft. 8½ in. by 3 ft. 6 in., and every square inch of which, on both sides, shows trucks of various types for every conceivable purpose. Several types of electric trucks are illustrated, such as electric crane trucks, electric tractors, electric lifting-tiering trucks, electric lifting platform trucks.

We have received from ARCHIBALD BAIRD & SON, manufacturers of high-grade steel castings, a loose-leaf booklet of illustrations, measuring 9 in. by 11 in. After excellent photographs of the works at Hamilton, near Glasgow, including a general view of the outside, the interior of the moulding, dressing, and engineering shops, and the power house, illustrations are given of the firm's manufactures—ship castings, gear wheels and blanks, mill spindles and coupling boxes, machine-moulded spur wheels, colliery castings, &c.

The RUNBAKEN MAGNETO COMPANY have issued a leaflet describing their new Ford ignition system, which gives two distinct forms of ignition (battery and magneto), and uses the magneto system installed on the cars The system, they claim, can be installed by anyone, without special tools, in forty minutes. Instead of four coils, with their troublesome tremblers, complicated connections, &c., a small transformer coil takes their place. There is one contact breaker and one h.t. distributor, both of which are quite accessible and simple in construction.

In an illustrated booklet entitled "Steam Generation," BABCOCK & WILCOX, LTD., deal with some of the developments which have taken place in their manufactures since the outbreak of the war in 1914. Among the more important of these are those in connection with their C.T.M. and W.I.F. boilers, chain grate, and forced and balanced draught stokers, traversing coal chutes, portable boilers, special furnaces, &c. In addition to the natural and forced draught chain grate stokers mentioned above, the company have acquired the right during the last twelve months to manufacture the Riley Underfeed stoker.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd, and the rubber prices by W. T. Henley's Telegraph Works Company.

Arrangements for the Week.

FRIDAY, April 21st (to-day).

ELECTRICAL POWER ENGINEERS' ASSOCIATION.
7 p.m. At Essex Hall, Strand, London, W.C. General Meeting.

JUNIOR INSTITUTION OF ENGINEERS.
8 p.m. At Caxton Hall, London, S.W. Paper entitled "Condenser and Choke Coil Protective Apparatus," by Mr. S. A. Stignant.

MONDAY, April 24th.

INSTITUTION OF ELECTRICAL ENGINEERS.
(LIVERPOOL SUB-CENTRE.)
7 p.m. At the Laboratories of Applied Electricity, the University, Brownlow-street, Liverpool. Paper entitled "Engineering Advertising and the Work of the E.D.A.," by Mr. J. W. Beauchamp.

INSTITUTION OF MECHANICAL ENGINEERS.
7 p.m. At the Institution, Storey's Gate, London, S.W. Paper entitled "Jigs and Tools," by Mr. B. A. C. Hills.

TUESDAY, April 25th.

INSTITUTION OF CIVIL ENGINEERS.
6 p.m. At Great George-street, Westminster, London, S.W. Annual General Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS.
(EAST MIDLAND SUB-CENTRE.)
6.45 p.m. At Loughborough College, Loughborough. Paper on "Electric Vehicles," by Mr. R. J. Mitchell.

INSTITUTION OF ELECTRICAL ENGINEERS.
(NORTH-WESTERN CENTRE.)
7 p.m. At the Engineers' Club, 17, Albert-square, Manchester. Annual General Meeting. Lecture on "Advertising and the Work of the British E.D.A.," by Mr. J. W. Beauchamp.

INSTITUTION OF ELECTRICAL ENGINEERS.
(SOUTH MIDLAND CENTRE.)
7.30 p.m. At the University, Edmund-street, Birmingham. Annual General Meeting.

WEDNESDAY, April 26th.

ROYAL INSTITUTION OF GREAT BRITAIN.
3 p.m. At Albemarle-street, Piccadilly, London, W. 1. A Lecture on "Industrial Relationships," by Prof. D. H. Macgregor.

ROYAL SOCIETY OF ARTS.
8 p.m. At John-street, Adelphi, London, W.C. 2. Lecture on "The Use and Advantages of Electric Power in the Factory, as Illustrated by its Application to the Jute Industry," by Mr. John Francis Crowley.

LIVERPOOL ENGINEERING SOCIETY.
8 p.m. At the Royal Institution, Colquitt-street, Liverpool. Annual General Meeting.

THURSDAY, April 27th.

ROYAL INSTITUTION OF GREAT BRITAIN.
3 p.m. At 21, Albemarle-street, London, W. 1. Lecture on "Audition and Colour Vision," by Prof. E. H. Barton.

THE NEWCOMEN SOCIETY.
5 p.m. At Caxton Hall, London, S.W. Papers on "A Note on Brunton's Walking Engine, 1813." by Mr. L. St. L. Pendred; "A Note on Heaton's Steam Carriage, 1828," by Mr. A. Titley; "Gurney's Railway Locomotives," by Mr. E. A. Forward.

INSTITUTION OF ELECTRICAL ENGINEERS.
6 p.m. At the Lecture Theatre of the Institution, Savoy-place, Victoria Embankment, W.C. 2. Lecture on "Protective Apparatus for Turbo-Alternators," by Mr. J. A. Kuyser.

LIVERPOOL ENGINEERING SOCIETY.
7.30 p.m. At the Royal Institution, Colquitt-street, Liverpool. Students' Meeting. Paper entitled "The Uniflow Steam Engine," by Mr. E. Cockshutt.

THE ILLUMINATING ENGINEERING SOCIETY.
8 p.m. At Royal Society of Arts, John-street, Adelphi, London. Discussion on "The Use of Light in Hospitals."

FRIDAY, April 28th.

ROYAL SOCIETY OF ARTS.
4.30 p.m. At Royal Society of Arts, John-street, Adelphi, London. Indian Section Meeting.

ELECTRICAL POWER ENGINEERS' ASSOCIATION.
7 p.m. At the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London. Lecture entitled "Some Notes on the Design of Generating Plant," by Mr. C. F. Hewitt.

INSTITUTION OF ELECTRICAL ENGINEERS.
(NORTH-WESTERN CENTRE.)
7.30 p.m. At the College of Technology, Manchester. Public Lecture on "Recent Developments in Atomic Research," by Prof. W. L. Bragg.

INSTITUTION OF ELECTRICAL ENGINEERS.
(SCOTTISH CENTRE.)
7.30 p.m. At Technical Institute, Dundee. Paper entitled "Single and Three-Phase Alternating Current Commutator Motors with Series and Shunt Characteristics," by Prof. S. Parker Smith.

JUNIOR INSTITUTION OF ENGINEERS.
8 p.m. At Caxton Hall, London, S.W. Lecturette. "Some Notes on the Utilisation of Water Power," by Capt. H. Whittaker.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by Messrs. Mewburn, Ellis & Co., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

Complete Specifications.

142 870 Nienhold, J. Apparatus for rectifying high and low-frequency alternating currents. (15/5/17.)
144 318 Hubers, G. X-ray plant. (27/3/16.)
144 738 Moses, W. B. Electricity generating and ignition apparatus for internal combustion engines. (29/6/17.)
145 018 Junger, E. W. Primary galvanic batteries and electrodes for such batteries and methods of manufacturing such electrodes. (17/6/19.)
145 042 Metallurgique Electrique. Suspension of electric traction wires. (19/2/14.)
145 422 Siemens-Schuckertwerke Ges. Arc lamps, more especially for searchlights. (20/8/17.)
146 354 Siemens & Halske Akt.-Ges. System for controlling relays by means of wave trains especially for wireless high-speed telegraphy. (27/5/19.)
146 530 Radio Corporation of America. Wireless signalling apparatus. (5/4/15.)
146 531 Radio Corporation of America. Thermionic valves for use in wireless signalling apparatus. (5/4/15.)
146 536 Radio Corporation of America. Apparatus for radio signalling. (1/2/16.)
146 538 Radio Corporation of America. Thermionic vacuum valve devices. (10/3/17.)
146 946 British Thomson-Houston Co., Ltd. Generation of electrical oscillations. (8/7/19.)
147 148 British Thomson-Houston Co. Ltd. Electron discharge devices. (29/10/13.)
147 153 Seibt, G. Telephones. (1/3/16.)
147 225 Vaile-Kimes Co. Automatic cut-out for electric motors. (16/6/15).
147 430 Ges. für Drahtlose Telegraphie. Wireless telegraph transmission. (24/12/15.)
147 439 Ges. für Drahtlose Telegraphie. Coarse and fine adjustment suitable for tuning and coupling devices for wireless telegraph apparatus. (10/11/17.)
147 445 Ges. für Drahtlose Telegraphie. Means for signalling to railway trains in motion. (4/2/19.)
147 446 Ges. für Drahtlose Telegraphie. Wireless receivers. (21/5/19.)
147 457 Ampere Ges. Process for producing ferrotungsten. (6/5/18.)
147 616 British Thomson-Houston Co. Ltd. Electron discharge apparatus. (16/10/13.)
147 627 Frankfurter Maschinen-ebau-Akt.-Ges. vorm Pokorny & Wittekind. Electro-motors. (18/3/16.
147 663 Kohler Co. Electric generating systems. (20/8/17.)
147 702 Ges. für Drahtlose Telegraphie. Production and control of high frequency currents in static transformers with auxiliary magnetisation, especially for use in wireless signalling. (26/2/14.)
147 718 Jacoviello, F. Combined resistance with hollow conductors. (21/12/17.)
147 756 Latour, M. Telephone and like systems. (23/5/19.)
147 772 Apple, V. G. Terminal bending tools for armatures. (11/12/16.)
147 773 Apple, V. G. Method of constructing armatures and stators for dynamo-electric machines. (30/12/16.)
147 775 Apple, V. G. Method of building commutators for dynamo-electric machines. (22/1/17.
147 776 Apple, V. G. Method of uniting armature terminals adapted for building commutators for dynamo-electric machines. (22/1/17.)
147 779 Apple, V. G. Starting and lighting apparatus for self-propelled vehicles. (23/4/17.)
147 780 Apple, V. G. Method of joining separated armature conductors and of making commutators from said conductors. (14/2/18.)
147 787 Apple, V. G. Dynamo-electric machines. (21/3/18.)
147 789 Apple, V. G. Methods of making armatures, and armatures produced thereby. (7/5/18.)
147 790 Apple, V. G. Method of connecting conductor bars of dynamo-machines. (20/5/18.)
147 792 Apple, V. G. Tool for bending the terminals of armature conductors. (23/12/18.)
147 802 Soc. Francaise Radio-Electrique. Electro-magnetic wave-receiving systems. (1/6/15.)
147 806 British Thomson-Houston Co. Ltd. Means for controlling electric currents and potentials by the use of electron discharge apparatus. (5/2/14.)
147 807 British Thomson-Houston Co. Ltd. Dynamo-electric machines. (16/1/17.)
147 808 British Thomson-Houston Co. Ltd. Electric motors. (14/2/18.)
147 811 British Thomson-Houston Co. Ltd. Wireless receiving systems. (15/6/18.)
147 812 British Thomson-Houston Co., Ltd. Electric starting systems for internal-combustion engines. (16/1/17.)
147 813 British Thomson-Houston Co. Ltd. High-frequency alternators. (23/9/16.)
147 814 British Thomson-Houston Co. Ltd. Means for transforming direct current. (29/12/13.)
147 816 British Thomson-Houston Co. Ltd. Wireless receiving systems. (11/10/17.)
147 819 British Thomson-Houston Co., Ltd. Electron discharge devices. (31/10/17.)
147 823 British Thomson-Houston Co. Ltd. Wireless signalling systems. (29/12/13.)
147 836 Soc. Francaise Radio Electrique. Wireless telephony systems. (24/2/17.)
147 851 Ges. für Drahtlose Telegraphie. Thermionic valve generators. (9/1/18.)
148 127 Kruh, O. Airtight metal cap connection for conducting electric current into hollow glass bodies. (6/7/17.)
148 130 British Thomson-Houston Co. Ltd. Production of metal films, particularly for use as electrodes in vacuum electric discharge apparatus. (6/6/14.)
148 131 British Thomson-Houston Co., Ltd. Generation of high frequency oscillations. (3/6/18.)
148 180 Ges. für Drahtlose Telegraphie. Transmitters of high-frequency oscillations. (6/11/18.)
148 321 Huth Ges., Dr. E. F. & Loewe, S. Wireless receiving apparatus. (20/12/15.)
148 324 Huth Ges., Dr. E. F. Electric coils for high-frequency purposes. (29/11/16.)
148 334 Schlotter, M. Process for the electrolytic production of dense and firmly adhering tin deposits. (15/3/17.)
148 522 Kruh, O. Airtight metal cap connection for conducting electric current into hollow glass bodies. (15/1/19.)
148 524 Ges. für Drahtlose Telegraphie. Electric conducting coils. (4/3/18.) (Patent of Addition not granted.)
148 786 Goldschmidt, R. Ground connections for wireless stations. (21/3/17.)
148 805 Allgemeine Electricitäts Ges. Coin-freed meter for electricity, gas, water or the like, provided with a device for making a minimum charge. (13/7/17.)
148 872 Schmidthammer, G. L. Production of electric carbons. (20/3/18.)
148 913 Gutmann, K. Holders and brackets for electric lamps. (14/2/19.)
148 978 Signal-Ges. Electro-magnetic submarine sound-signalling apparatus. (1/11/18.)
148 979 Signal-Ges. Electro-magnetic sound-transmitting and receiving apparatus with two exciting windings. (18/11/18.)
149 236 Allegemeine Electricitäts Ges. Three-arm choking-coil or transformer with inductance variable by continuous or alternating current of low frequency. (17/9/14.)
149 268 Coninck, M. R. de. Electric propulsion of ships. (15/7/19.)
149 345 Philipps Akt.-Ges. Magneto-electric lamps. (24/7/19.)
149 973 Bardeloni, C. Receiving methods of radio-telegraphic and radio-telephonic signals. (10/1/18.)
151 243 Apple, V. G. Method of constructing armatures for dynamo-electric machines. (15/9/19.)

APPLICATIONS FOR PATENTS

April 3, 1922.

9 489 R. Bosch Akt.-Ges. Electro-magnetically operated hooters. (18/4/21, Germany.)
9 519 O. L. Kleber. Printing telegraph machines.
9 521 Patent Trenhand-Ges. für Elektrische Glühlampen. Electric gas lamps with glow discharge. (4/4/21. Germany.)
9 526 Western Electric Co. Telephone repeater systems.
9 527 Western Electric Co. Telephone exchange systems.
9 529 E. W. Dorez. Electrostatic condensers.
9 532 B. T.-H. Co. (G. E. Co.). Supporting devices for pointers, needles, &c.
9 547 Aeronautical Instrument Co. Earth inductor devices. (13/8/21, U.S.)
9 560 J. S. Ross. Devices for recording telephone calls.
9 569 Soc. Anon. pour l'Exploitation des Procedes M. Leblanc-Vickers. High speed electric machines. (16/4/21. France.)
9 579 W. H. Meyrick. Anchoring conductor rails.

April 4, 1922.

9 590 J. R. C. August & E. K. Hunter. Electric control means.
9 593 G. W. Hawksley. Device for magneto testing.
9 640 Woods-Gilbert Rail Remodelling Co. Machines for dressing rails.
9 685 W. F. Topley & F. H. Robinson. Electric railway signals.
9 686 F. W. Le Tall (Westinghouse Electric Supply and Mfg. Co.) Frequency regulators for a.c. circuits.

April 5, 1922.

9 742 W. J. Newman. Cycle dynamo lamps, &c.
9 763 T. F. Wall. Means for rectifying alternating currents, &c.
9 768 A. A. King. Electric torches.
9 770 N. Clough. Systems of electric traction and suspension of overhead conductors.
9 775 S. W. Bligh & E. L. Crowe. Amplifying wireless signal currents to work recording instruments.
9 786 Cie Franc. pour l'Exploitation des Procédés Thomson-Houston. Safety devices for switch hooks of telephone instruments. (8/4/21, France.)

April 6, 1922.

9 842 F. Addie & A. G. Hartley. Electrical control gear.
9 874 W. R. Macdonald. Electric motors.
9 876 H. E. Holman. Electric mincer.
9 886 Measurement, Ltd., & F. Holden. Prepayment electricity meters.
9 902 F. C. B. Chase. Insulating device.

April 7, 1922.

9 911 A. M. Taylor. Reducing self-induction and eddy current losses in underground electric cables.
9 912 W. E. Roberts. Devices for ensuring electrical continuity in steel conduits.
9 924 L. J. Vann. Electric machines.
9 925 Fuller's United Electric Works & R. E. Beswick. Vents for storage batteries.
9 926 J. G. Thomson. Utilising tidal energy for generating power.
9 929 Townshends, Ltd., & E. Townshend. Detachable connectors for connecting flexible cables to kettles, &c.
9 931 P. G. Barden. Automatic time switch for electric light.
9 941 Parker, Winder, & Achurch, & J. F. Pennefather. Incandescent lamps.
9 947 Crompton & Co. & W. F. Jones. Automatic circuit-breakers.
9 960 F. E. Pernot & L. J. Rich. Selective reception of alternating currents.
9 968 P. Rombach. Electric pocket lamp.
9 970 O. R. C. Sherwood. Amplifiers for wireless telegraphy, &c.
9 982 B. T.-H. Co., H. C. Hastings, & C. T. Hanna. Motor control.
9 992 A. J. Church. Carbon holders for arc lamps.
9 997 Western Electric Co. Long telegraph cables. (16/8/21, U.S.)
10 002 A. E. O'Dell (Lorenz Akt.-Ges. & Scheppmann). Method of receiving in telephony and wireless telegraphy and telephony.
10 003 Schweizerische Gasapparate Fabr. Solsthurn u. Elektra Fabr. Elek Heiz u. Kochapparate. Electric regulating resistances for switches, &c. (13/4/21, Switzerland.)

April 8, 1922.

10 016 R. Bosch Akt.-Ges. Battery ignition devices. (17/5/21, Germany.)
10 028 O. Zinke. Apparatus for recording telephone conversations.
10 031 Stamping & Spinning Works, Ltd., & N. L. Penn. Dimmer Switches for motor vehicle lamps.
10 043 J. Hampson & R. Olsen. Electric switches.
10 058 F. E. Pernot & L. J. Rich. Multiplex telegraphy.
10 082 C. O. Bastian. Positively indicating completion of magnetic change in carbon steel under heat treatment.
10 084 Telegraph Condenser Co. & W. J. Cole. Electric condensers.
10 088, 10 092, 10 093, & 10 094 H. S. Conrad. Telephone systems.
10 089 H. S. Conrad. Apparatus for automatic telephone systems.
10 090 & 10 091 H. S. Conrad. Telephone switching mechanism, &c.

The Editorial, Advertisement and Publishing Offices of "The Electrician" are at 8, Bouverie Street, London, E.C. 4. Telegrams: Benbrotric, Fleet, London. Telephone: City 9852 (5 lines).

The subscription to "The Electrician" is £1 5 0 per annum in the United Kingdom and £1 10 0 per annum Abroad. Advertisement Rates can be obtained on application to the Manager. Advertisement copy and blocks should be received on the Friday preceding date of publication.

THE ELECTRICIAN

ESTABLISHED 1861.

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

Electrical Engineering, Industry, Science and Finance.

No. 2293. [Vol. LXXXVIII. No. 17.] FRIDAY, APRIL 28, 1922. Prepaid Subscription U.K., £1 5s. per ann.; Abroad, £1 10s. Price 6d.

CONTENTS.

Notes of the Week.

The Great Question.

Is taxation going to be reduced? That is the question of the moment to which the answer will be supplied by the Chancellor of the Exchequer on Monday. Like all questions of its kind, the answer will not depend solely on financial or industrial considerations, but will be influenced by those political undercurrents which are the evil genius of our time. Taxation cannot be reduced, say the Treasury officials, without resource to unsound methods of finance. If taxation is not reduced, say Lord Inchcape and the City of London, we shall land, "unless we act promptly and resolutely, in the ditch." How are these two expert opinions to be reconciled? Lord Inchcape supplies the best answer: By a reduction of expenditure, a simple course to which the Government are as averse as ever was Naaman the Syrian when he was told what to do.

A Bold Course the Best.

But even if expenditure be not drastically reduced, and only allowed to fall by the soft and easy methods beloved of the Government, the reduction of taxation is a course, bold it may be, but still essential for the end in view. The present high rate of income tax, the Corporation tax, the penal excise duties are not only strangling trade but are failing to produce the expected revenue. Were the income tax to be reduced, and the Corporation tax abolished, it might be that the stimulation given to trade would result in no falling off in revenue. Sir Robert Peel tried the experiment about eighty years ago, and it was successful. It would certainly be worth repeating.

The Intricacies of Armature Winding.

There are some branches of electrical activities which ever remain a mystery to those not intimately engaged in them. When questions connected with them crop up the only difference between the average electrical engineer and the rest of the world is that the former is distressed because he feels he ought to know, while the latter proceeds on his way in blissful ignorance, or the certainty which is akin thereto, but generally in still more blissful indifference. We might cite as an example of what we mean much of the modern complicated work in telephony into which Mr. Aitken periodically gives readers of The Electrician an insight, but more to the point will be the contents of the article on "Practical Armature Winding Formulæ," which Mr. L. Wollison contributes to this issue. Outside the specialists' drawing office and the designers' den the armature winding diagram is a thing of mystification to most. Little less mystifying is the armature actually being wound in the shops. It is therefore a relief to find that many of those who wind armatures do not understand the theoretical diagrams, and it is to their rescue, and incidentally to the rescue of the more general reader, that Mr. Wollison therefore comes. Equally true, of course, is it that many of those who can design armature windings cannot wind armatures, but that is another story.

A Plea for Simplicity.

Summarised, Mr. Wollison's arguments are a plea for simplicity. The winder, he says, when given an armature containing a certain number of slots and commutator segments requires only to know the pitch between the two sides of any coil in the slots, in terms of the slots, and the pitch between the two segments of the commutator, to which the two ends of any unit are connected, in terms of the segments. It is possible to express any type of series drum d.c. winding of any degree of multiplicity or re-entrancy in terms of the segments by a simple formula for which is necessary to know nothing beyond the number of segments in the commutator and the type of winding. Mr. Wollison

supports his arguments by means of numerous examples and makes out so good a case that we feel sure he will bring relief not only to those for whom he primarily writes but for electrical engineers at large.

Pure Science and its Applications.

The series of lectures on "Radioactivity," recently given at the Royal Institution by Sir Ernest Rutherford, of which we conclude our account to-day, not only bring together in readable form much information on an important subject, but indicate how our knowledge of the disintegration of substances, which were at one time thought indivisible, both into new substances and into those already known in another form, is increasing. It is a branch of investigation which has always had a fascination for scientific workers since the days of the early alchemists, though the methods employed and the fate meted out to those engaged in it are vastly different. For with investigators in radioactivity like Sir J. J. Thomson and Sir Ernest Rutherford disintegration has been an incident in a genuine search after further knowledge rather than a means to earthly riches and power. It is not unlikely, however, that these researches in the purest of pure physics may have some considerable application. Such a thing has happened before and doubtless will happen again until we are almost led to contend that there is no field of theoretical investigation from which some useful data of practical application may not be derived.

Amateur Wireless.

Progress in wireless communication assumes different forms in accordance with the different viewpoints of the observer. To the expert this progress is reflected in patent specifications, in articles in technical journals, or in Papers read before scientific societies. To the amateur, progress means an increasing facility in reading signals owing to a development in his own aural skill or in the discovery of the idiosyncracies of his apparatus. To the newspaper man, wireless progress means the more speedy and more general dissemination of news. For the amateur and for the newspaper man, therefore, improvement in wireless telephony especially opens up new vistas of enjoyment and new possibilities. Some of these are not without their drawbacks, and the newspaper man is more than a little fearful of one phase at least of this possible development.

Wireless Telephony and Civilisation.

The statement of Mr. Godfrey Isaacs that wireless telephony is destined to play a great part in every country in future has therefore had as an immediate result the publication of all sorts of special articles and opinions on this important question from the two points of view we have just mentioned. Technical opinion is naturally silent in these discussions, though without its help these developments will be quite impossible and can only progress with its continued assistance. Here, however, there should be no great difficulty. Equally easy should be the path of the amateur, and contentment should be his lot, providing he can resist the temptation to think life incomplete without a licence for transmitting, a facility which we hope will be most sparingly granted. For there are already complaints in this country that important wireless services are being interfered with by messages from privileged amateurs, and in America the confusion has been so great as to cause the Government to appoint a Committee to consider the whole question. Indiscriminate, even limited transmission, is unnecessary, and should be strictly controlled. Our streets are crowded and noisy enough to make us wish that the Heaviside layer should be kept free from similar distractions.

News, Not Comment.

This limitation however imposes this great responsibility on Government: that the information sent out by wireless telegraphy or telephony to be picked up by innumerable newspaper or amateur stations, as Mr. Isaacs envisages, should be news in the truest sense of the word uncoloured by comment and free from the suspicion of propaganda. If the wireless amateur finds it difficult to resist the temptation to transmit, much more difficult will the Government find it to resist, as they must resist, the temptation to use wireless news service for anything but pure news. If, however, that is done, not only will the propagation of information be possible with an accuracy, speed and fulness unknown to-day, but the wireless industry will enter an era of unbounded prosperity, which is, of course, the matter with which we are most concerned.

Railways and Electrical Men.

As we recently pointed out, the organisation of electrical work on our main railways is not without its injustices and its illogicalities. The "Railway Gazette" emphasises this by recalling that on the London and North Western Railway the signal department was for some time under the chief mechanical engineer, but is now under the chief engineer (on railways the officer who looks after civil engineering work). For a time the telegraph department was a separate unit, then it came under the signal superintendent, and finally under the electrical engineer when Col. Cortez Leigh was appointed to that position. Now the chief engineer once more holds sway over its destinies, as is the case on most other railways except the Great Western, where Mr. Blackhall supervises both the signals and the telegraphs. On the Midland there is a different division of duties, the telegraphs, telephones and overhead work connected with electric traction coming under Mr. Sayers, as telegraph superintendent, and the generating plant and electrically equipped rolling stock under Mr. Dalzell, of the chief mechanical engineer's department.

The Need for a Railway Electrical Engineer.

In practice probably the confusion is not so great as in theory. Nevertheless, we hold to our opinion that all electrical work on a railway should be placed under an electrical engineer, who should be a chief officer with direct access to the general manager. If the telegraph and telephone systems are so closely connected with the signalling that the signal superintendent must exercise supervision over them in practice, the whole of the electrical work should certainly be carried out in consultation with the electrical engineer. It is time the electrical department ceased to be considered as a Cinderella and be made what it is, one of the most important links in the whole machine.

The Engineers' Dispute.

The conduct of negotiations between the parties to recent industrial disputes have followed a well trodden path. Both sides have viewed with apparent indifference a movement towards a stoppage of work, and even after that stoppage has occurred, though conferences innumerable have been held, there has been an equally apparent reluctance to come to terms, until a longer or shorter period of stagnation of production has elapsed. Meanwhile, much damage is done to both sides, and in the result either side is little, if any, the better. It is not much of an advertisement of the tact and diplomatic capacity of either side or

of the much vaunted national characteristics of sanity and levelheadedness.

Qualities for Settlement.

The engineers' dispute seems about to run the same disastrous course. After days of alternate hopes and fears it looks at the time of writing as if the lock-out, far from being raised, will be extended to the members of the other forty-seven unions concerned, and that 1 000 000 workmen in the engineering and shipbuilding industries will be rendered idle. This is to take place at a time when trade is said to be reviving, and when high hopes of still further stimulation from reduced taxation are in everyone's mind. And the worst of it is it all seems about so little. For even the lengthy statements which are issued by both sides are but reiteration and embroidery of the simple fact that no formula can be found which gives employers control in their own works and at the same time safeguards the workers against apprehended injustice and oppression. We fear that the reason why such a formula cannot be found is that stubbornness is prevalent on both sides, that goodwill is lacking, and that fatalism is stultifying that moderate opinion which should be working for peace. But the present state of deadlock cannot go on indefinitely, and the sooner, therefore, that it is resolved the better for all parties. As Sir Charles Macara says: "It is high time an end was put to the folly."

Storms in Teacups.

Is there something in the electricity supply industry which makes for a highly-charged atmosphere? It certainly seems so, for quite small matters have a way of suddenly expanding out of all semblance to their initial proportions. The latest example is the Chelmsford dispute, where a jointer, in a way jointers have, refused to connect up non-union wiring to the mains. The District Council forthwith passed a resolution of the high-explosive type and transmitted it to the National Council for discharge. Now we hear rumblings which we are meant apparently to regard as the crackings of the foundations of the Whitley Council movement. But we decline to visualise the edifice rocking. For in our opinion the industrial councils are far too firmly set on their foundations to be endangered by such surface vibrations.

What is the Issue?

But, after all, what is the issue in all these cases from the trade union side. Merely an attempt to force a few small wiring contractors to observe union conditions. Often these contractors are merely "one man firms," and are not worth powder and shot. On the other hand the trade unions have everything to gain by relinquishing their present doubtful methods of refusing to connect up the work done by such people. For such a policy puts the electricity supply undertakings in a difficult legal position. The unions must realise this; and realise too that their policy must in the long run endanger that goodwill which has been so vastly augmented by the three years working of the industrial councils. As a matter of fact, it speaks volumes for the goodwill existing between both sides, that this guerilla-warfare, carried on by the unions in the territory of the undertakings, has not resulted in an open breach of the peace. The dispute is, in fact, still in the realms of friendly negotiation. We certainly hope that the trade unions will concede this point, especially in view of the fact that the mere settlement of an awkward dispute of this kind by the Council will give added prestige to the Whitley movement, and establish it more firmly than ever.

British Electric Transformer Progress.

The Reports of a manufacturing company like the British Electric Transformer Company may be taken as a good index of the steady advance of the electricity supply industry, for the company manufactures equipment and domestic apparatus to meet the demands of new consumers. It is therefore satisfactory to learn that the past year's working of the Company is a record, the net profit being £91 417, compared with £70 267 in the previous year, and £48 053 in 1919. After placing £15 000 to reserve (against £10 000 in 1920), the directors are able to pay an ordinary dividend of 10 per cent. with a bonus of 2½ per cent., as in the three previous years, while a sum of £12 700 is carried forward, or £6 500 more than in the previous year. It should be noted the growth of the net profit has kept pace with the increase in the capital, and the figures in the accounts therefore indicate that the Company's business is sound and expanding. As progress is made with the reorganisation of electricity supply, and as the charges for electrical energy are lowered there should be an increasing demand for the Company's products, and even better results may, therefore, be anticipated in future years.

South American Ideas of Justice.

The actions of the Governments and municipal authorities of South American republics are sometimes as weird and peculiar as those of the heathen Chinee. The latest performance of the Monte Video Council, therefore, only adds one more chapter to a history which is not without its purple patches. Swayed by strange influences as our local authorities sometimes are, they do not go about seizing the undertakings of the private companies. Yet this is what recently happened to the United Electric Tramways of Monte Video, and to another tramway company operating in the same city. It is obvious that if this sort of thing is going to occur often, no British company, or company of any other nationality, will rush to own and operate electricity supply, electric tramways, or other public undertakings in South American towns, and that, as the management of these undertakings does not seem to be within the capacity of the local inhabitants, the facilities for transport and lighting in these cities will suffer considerably.

How the Trouble Arose.

What makes the matter more interesting to English companies is that the trouble apparently arose over the fares question. The company's concession contains provisions fixing the fares that might be charged; but during the war, and since the Armistice, no increase to meet the great rise in the cost of materials, and of higher wages paid to employees, has been permitted, in spite of the fact that about four years ago, when the company applied for sanction to such increases, the matter was fully discussed, and a Government Committee made a favourable recommendation. To make matters worse, the Government has recently been dabbling in social reform, which, as our own experience has shown, has added heavily to the expenses of the company; while, adding insult to injury, the company's employees came out on strike recently for a still further wage increase, which the company naturally refused to grant. When the strike commenced, the Gilbertian municipality ordered the company to resume its services, or in default to pay a fine of $50 a day for each car that was not running. The company, however, did a little refusing on their own account, and after the strike had lasted over three weeks, the municipality instructed the defaulters to return

to work, and promised them the increased wages at the company's cost, thus successfully fulfilling the creed of the modern socialist of being generous at somebody else's expense. The underaking is now being operated under municipal control, the wages required being forcibly taken from the company's receipts. We should imagine there would be no great rush to obtain tramway concessions in South America, or even to emigrate there if the Geddes axe fails to fulfil its functions.

The Miners and Electric Coal Cutters.

The Miners' Federation, fresh from more or less successful attempts to settle the wages question in their industry, are turning their attention to electrically operated coal cutters, whose use, they contend, should be confined to mines where no gas is present. This is very subtle. For in effect it would practically prohibit the employment of coal-cutters, and is therefore significant of the unenlightened attitude with which Labour still regards the employment of machinery generally. With their contention that such machinery should be faultlessly designed and properly operated by skilled workmen we can, however, agree. That the second condition is not always fulfilled is clear from the evidence recently given in a compensation case at Glasgow. Here the coal-cutter was a specially designed flame-proof machine, in perfect working order; but an accident occurred owing to a workman neglecting, as so often happens, to exercise ordinary care.

An Unwise Decision.

The cause of the accident was the failure of a workman to screw down a switchbox cover, so that the gas was ignited by the flame. The sheriff held that taking off and fixing such switchbox covers was not a skilled electrician's work, but could be performed by a man operating the coal-cutter. This decision seems to us to be unnecessarily general, and is, in fact, in the letter, and not in the spirit, of the regulations for the use of electricity in mines. Taking off of a switchbox cover in a gaseous mine is a dangerous if not a difficult operation, and should, therefore, only be effected by a skilled person, especially as the safety of the workers largely depends on proper precautions being taken, and on no unnecessary risks being incurred.

The Relief of Rates Again.

One of the principal arguments against municipal electricity supply is that the committee in charge of the undertaking may allow its political bias to direct its actions to gain some temporary financial advantage in a way which no prudent board of directors would sanction. For instance, in pre-war days it was a common practice to raid the tramway and electricity accounts for sums which should have been allocated to reserve or depreciation in order to reduce the rates or to wipe out deficits elsewhere. We regret to notice that this practice is being revived, for it is finance of the worst kind to take sums from the " profits " of the electricity supply department until a substantial reserve has been provided and until the price of electrical energy has been reduced to as low a figure as possible.

Cardiff's Unwise Action.

We regret, therefore, to see that Cardiff City Council has again agreed to the proposal of its Finance Committee that £5 000 of the estimated electricity profits be applied for the " relief of the rates." It is true that in the past the undertaking has made contributions to the rate fund because it owed money which had been lent to meet deficiencies in its early years. There is no objection to this, but relief *ad hoc* from " profits " is another matter, especially as in 1921 the Electricity Committee contributed £15 000, a sum which more than repaid the outstanding debt. The Finance Committee now, however, wish to adopt a settled policy of a regular annual contribution out of the profits. This is most retrograde.

The Argument for Relief.

It is argued in support of this procedure that if the electricity department had gone to the public as a private enterprise to get £400 000 capital it would not have been able to borrow at anything like so low an interest as it is paying. The difference is put at about 1½ per cent., and the Council were, therefore, asked to adopt the principle of requiring their trading departments to contribute at the rate of 1½ per cent. on the capital raised. This is a plausible but not very convincing argument, and though the electricity department will have to part with £5 000 this year the question of applying the general principle, which was strongly opposed by some members, has been deferred for further consideration.

A Matter for the Ratepayers.

In the meantime we hope that the consumers who provide the money out of which the contributions are to be made will organise opposition to the proposal. We contend that the first duty of the electricity department is to provide a cheap supply for its customers, and next to develop the undertaking by extending the service to the remainder of the city. This cannot be done if any surplus is to be periodically raided to provide doles. In a city like Cardiff £5 000 cannot represent a penny rate. On the other hand, if this sum were devoted to reducing the prices, which is still 75 per cent. above the pre-war rates, or even in extensions of the mains, the city would reap a far greater advantage. We hope, therefore, that the Corporation will not sanction the principle of a regular annual contribution to the rate funds.

Australian Industrial Arbitration.

Compulsory arbitration in industrial disputes has been in operation in Australia since 1904, and though it has been obvious for a long time that the system was breaking down, it has only now been acknowledged to be a failure by the Commonwealth Premier. It will be remembered that the awards of the Conciliation and Arbitration Court were binding on employers and nominally on the employees, but the militant unions frequently flouted the decisions of the court; strikes continued, and in the end recourse had to be had to special tribunals. Australia has made itself conspicuous by its experiments in advanced labour legislation, but, as we learn by the failures as well as the successes of others, it will be interesting to watch the fate of the substitute which Mr. Hughes proposes to adopt instead of compulsory arbitration. It is now suggested that these tribunals be composed of equal numbers of employers and employees, with an independent chairman, who is not to be a lawyer. This is a body not unlike the Victorian Wages Board, which is claimed to be simple in operation, and has proved fairly satisfactory in industrial disputes in that State. It will be agreed that anything which would put a stop to or minimise industrial strife, the bane of modern civilisation, should receive careful and sympathetic consideration, and we shall watch with interest the outcome of Mr. Hughes's new idea.

International Electric Traction.

The meeting of the International Railway Congress in Rome last week was fortunately seized as an opportunity for putting forward a collection of up-to-date information on the position of electric traction in the various countries of the world. Reports which have already been published by the Association were presented and contained accounts of the conversion work now in hand in the United States, Italy, Switzerland, Great Britain, Holland and Scandinavia. From these, and more from the comments on the design, practice and performance of the equipment employed on electric railways, it is possible to draw conclusions and so construct a useful leaping-off place for future progress.

It is quite evident that in all its phases electric traction is still in a state of fluidity. Owing to great differences of opinion on questions of practice and performance, it has not begun to crystallise, and should not be allowed to do so. For with our present limited knowledge of its problems, if we try to dogmatise we are likely to be led into errors which future experience will show to be profound, and from which the escape will not only be difficult but expensive.

The United States.

Turning first to the United States, as the country where both the theory and performance of electric traction are more advanced than elsewhere, we find Mr. George Gibbs reporting that all railway conditions have been successfully met by electric traction, including city terminal operation, long tunnel operation, passenger and goods haulage, suburban passenger services, heavy grade freight traffic, and main line operation. Mr. Gibbs, we know, is an enthusiast, but the facts and figures which he puts forward seem effectually to dispose of the argument that there are certain classes of traffic with which electric traction cannot deal, and throws us back on the much more difficult problem of determining whether and when it is possible, economically, to bring about the conversion which, as abundantly appears, is an advantage in all countries, and highly remunerative in the savings it allows in others.

King Charles Again.

On the question of the system which permits the greatest advantages to be obtained, that King Charles' head which cannot be kept out of any discussion on electric traction, Mr. Gibbs is less definite. To some of those who are enthusiasts for electric traction he even may appear less sound. Surely, some will argue, the experience which has been gained in the United States with electric traction should have made it possible by this time to say that one or other of the numerous possible systems is the best. The fact that it has not been possible is itself the answer to this implied question. No " best " system has yet been found because there is none to find. The most that Mr. Gibbs can do to help towards that impossible ideal is to ban rather mildly the 3 000 V direct current system on the score of difficulties in current collection, to bless hardly more enthusiastically the 11 000 V alternating current system on the grounds that it can meet all the conditions of current collection on American railways, and to point out that the overhead conductor is likely to blossom, while collection by contact rail, though it can provide sufficient current carrying capacity even at low voltages, is likely to fade.

Italy and Switzerland Favour Overhead.

Inferentially the same conclusion has been reached in Italy, where in fact the increasing use of the three-phase system leaves little choice, and very much more definitely has it been reached in Switzerland, where the single-phase system is considered, under Swiss conditions, the most favourable, both technically and economically, for main and other lines. In Scandinavia the single-phase system has also been adopted, of course with overhead equipment, though France and Holland have decided in favour of high tension direct current traction. In the latter case the choice was made because the advantages were more patent where there is only medium density of traffic, and especially because the numerous level crossings and bad soil are against the use of the contact rail.

The British Position Through Dutch Eyes.

The position in Great Britain is, of course, well known. We have standardised, and yet we have not standardised. We are apparently wedded to a system to which most other countries object, in spite of the fact that, as Mr. Van Loenen Mentinet, chief of electric traction on the Netherlands State Railways reports, there is no material difference between the systems in costs of installation, upkeep or efficiency; and though, as we have pointed out, the single-phase system has great advantages in simplicity of generation, transmission and transformation. On the other hand we have, it is believed, a loophole by which, with the sanction of the Ministry of Transport, a railway company may adopt any system that meets its own needs best, a loophole of which full advantage is not unlikely to be taken.

How Far is Standardisation Necessary.

We hope that one of the questions which the International Congress will bring out clearly is how far standardisation of system is economically necessary, not only for an entire country but for the whole area covered by one large railway group. Because, for instance, the new London and North Western Railway group finds it best to use the conventional d.c. system in the London suburban area, and between Liverpool and Southport, and the high-tension d.c. system between Manchester and Bury, is it to be debarred from using the single-phase system over Shap Fell or between Derby and Manchester because, though that system has been proved best for such difficult sections, it runs counter to the gospel of standardisation?

Very Nearly the Whole Truth.

In this connection we think Mr. Gibbs' words are worth a moment's pondering. It is " too early to fix the features of any one system to the extent required for purposes of standardisation without restricting development."

It is, therefore, to be hoped that the greatest result of this useful Congress will come from the interflow of ideas which it will render possible. Each enthusiast—and most electric traction engineers are enthusiasts now-a-days—will be able to learn from supporters of opposite views something which will bring about the softening of prejudices and make the reception of new ideas easier. Each problem, be it connected with system, design or performance, can be dealt with *de novo*, and the solution sought will be the one most likely to satisfy the requirements of particular needs. In electric traction we are only beginning. It is too early to say what is the best, though we should be right to be satisfied with nothing less. From this point of view we are glad to see that more technical matters than the choice of system were taken up in the reports and discussed at the meetings, and to those we shall refer in a subsequent issue.

Practical Armature Winding Formulæ.

By L. WOLLISON.

The object of this article is the simplification of the usual armature winding formulæ for the benefit of the man in the workshop. The operative is chiefly concerned with two practical considerations, the pitch between any two sides of a coil in terms of the slots and the pitch between the segments of the commutator, to which the two ends of any coil unit are connected, in terms of the segments. Taking these as his basis Mr. Wollison works out a number of practical examples, and shows that for any type of series drum d.c. winding it is possible to express the commutator pitch in terms of the segments without knowing anything beyond the number of segments and the type of winding.

While lecturing on the subject of "Practical Armature Winding" to students engaged in that trade, the writer has been impressed with the extreme difficulty which confronts the average worker who seeks reliable information in simple practical terms, regarding the principles which underlie the various modern types of d.c. armature windings.

In the majority of text-books this subject is dealt with largely, if not entirely, from the design point of view, and in terms which necessitate a fair knowledge both of mathematics and the general principles of electrical engineering. In particular, the methods of determining the winding pitches—the all-important subject both theoretically and practically—are usually involved in terms and formulæ which are as Greek to the man in the workshop; especially is this so in the case of multiplex d.c. windings of various re-entrancy.

The Drawbacks of Prevailing Methods.

The prevailing method of explaining the winding pitches in terms such as "Front," "Back," and "Mean" pitch (y_f; y_b; and y) as measured in "coil sides" or conductors is

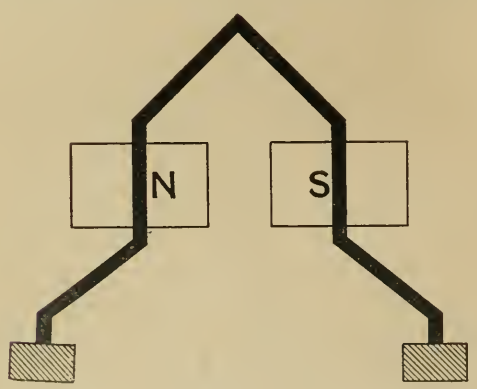

Fig. 1

needlessly confusing to the man who has to do the actual winding. He is chiefly concerned with two practical considerations. Given an armature containing so many slots and commutator segments he seeks two pieces of information; first, the pitch between the two sides of any coil in the slots, *in terms of slots*; and second, the pitch between the two segments of the commutator to which the two ends of any unit are connected, *in terms of segments*. In other words, if one side of a coil is placed in slot 1, in which slot should the other side be placed? and, similarly, if the one end of a unit is joined to segment 1, to which segment should the other end be connected?

A little consideration will show that these two factors completely determine an armature winding of any modern type. In point of fact, the multiplicity, re-entrancy, progression and number of circuits are all determined in any d.c. armature winding by the commutator pitch alone. It may, therefore, be of interest to show that these pitches for any type of simplex or multiplex winding can be simply expressed in terms of slots or segments, without involving anything more than simple arithmetic.

Two Initial Definitions.

For this purpose two initial definitions are necessary:

UNIT = One or more turns (each of two conductors) in series, the two ends of which are joined to certain commutator segments. Fig. 1 shows a one-turn unit.

COIL = One or more units assembled together in the same two slots of the core. (Thus with a winding containing 125 units in twenty-five slots, each coil would consist of five units.)

From this it will follow that as each commutator segment is joined to one end of each of two units there will be as many segments as there are units in any winding.

In dealing with the pitch of the winding in the slots of the core, the winder is necessarily chiefly concerned with coils and slots. As it is essential that for good commutation and maximum efficiency the pitch of the coil should correspond as nearly as possible with the pole pitch of any machine, the pitch of the coil or the core-pitch, as it is generally termed, will be the same for any type of winding, and in the vast majority of cases may be expressed:

$$\text{Core-pitch} = \frac{S}{P} = N \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

or where necessary:

$$\frac{S \pm 1}{P} = N \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (2)$$

in terms of slots; where S = slots, P = poles and N = any whole number. A certain amount of latitude is possible with the core-pitch, a little variation one way or the other having only slight effect on the capacity of the machine. For fully 90 per cent. of machines of British manufacture the above two expressions will serve. Three examples will suffice in this respect.

Example (*a*). An armature for an eight-pole machine has 144 slots. The core-pitch will be:

$$\frac{144}{8} = 18 = \text{Step of } 1\text{—}19$$

(*i.e.*, the coil will occupy the bottom half of slot 1 and the top half of slot 19 or *vice versa*).

Example (*b*). A four-pole armature contains thirty-nine slots:

$$\text{Core-pitch} = \frac{39+1}{4} = 10 = \text{Step of } 1\text{—}11.$$

Example (*c*). The windings of a four-pole armature are arranged in twenty-five slots:

$$\text{Core-pitch} = \frac{25-1}{4} = 6 = \text{Step of } 1\text{—}7.$$

Some Examples of Series Drum Windings.

With the span of the unit across the commutator (or the commutator-pitch) absolute accuracy is required as the slightest alteration may enormously affect the rating of the machine

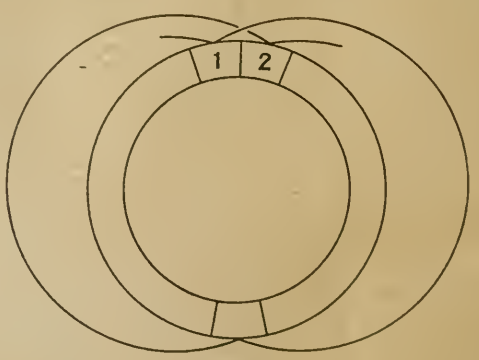

Fig. 2.

In any of the following examples only series drum windings will be referred to. Consider first an ordinary simplex re-entrant winding (◯). This is of the type shown in Fig. 2, which represents a portion of a four-pole series winding. Here it is obvious that, as all the units are equal in every respect

and are of equal pitch, the entire segments of the commutator plus or minus 1 (according as the winding is progressive or retrogressive) are spanned by $\frac{P}{2}$ units.

Hence for all simplex re-entrant series windings :

$$\text{Commutator pitch} = \frac{U \pm 1}{p} = N \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (3)$$

where U = total effective units in winding, or commutator segments ; p = pairs of poles, and N = any whole number.

Example (*d*). A four-pole progressive winding has 125 units (or segments) :

$$\text{Commutator pitch} = \frac{125+1}{2} = 63 = \text{Step of } 1-64$$

in terms of segments, *i.e.*, the winding starting at segment 1 will pass through the first unit to segment 64 ; through another

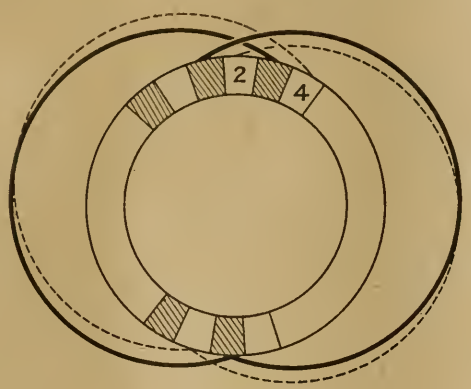

Fig. 3.

unit to segment 2 (= 127—125) and so on until it finally closes at segment 1. It is, of course, obvious that all commutator pitches must be whole numbers, as the end of a unit cannot be connected to the fraction of a segment.

Duplex Doubly Re-entrant Series Winding.

Next consider a duplex doubly re-entrant series winding (○ ○). This in effect is two separate simplex windings interspaced in the core and commutator (Fig. 3). In this case it will be found that one winding connects with all the segments of odd number, and the other winding to segments of even number. The two windings are electrically separate. It will follow, therefore, that $\frac{P}{2}$ units will span the entire segments of the commutator plus or minus 2.

The formula for any duplex doubly re-entrant series winding is therefore :

$$\text{Commutator pitch} = \frac{U \pm 2}{p} = 2N \quad \ldots\ldots\ldots\ldots \quad (4)$$

(Since the commutator pitch for a simplex winding = N, it should be clear that for a duplex winding, consisting of two separate windings, the commutator pitch must = 2 N).

Example (*e*). A six-pole duplex doubly re-entrant retrogressive winding contains 122 units (61 per winding).

The commutator pitch is $\frac{122-2}{3} = 40$ ($N = 20$) = Step of 1—41.

Winding A passes round the commutator in the order :

1—41—81—121 &c. and winding B :
2—42—82—122 &c.

Similarly for a triplex trebly re-entrant series winding (○ ○ ○) (three electrically separate simplex windings), as each winding is connected to every third segment, it follows that :

$$\text{Commutator pitch} = \frac{U \pm 3}{p} = 3N \quad \ldots\ldots\ldots\ldots \quad (5)$$

Example (*f*). A four-pole triplex trebly re-entrant progressive series winding contains 297 units (or segments).

$$\text{Commutator pitch} = \frac{297+3}{2} = 150 = (N = 50) = \text{Step } 1—151.$$

The passage round the commutator will be :

Winding A 1—151—4 = (301—297) &c.
Winding B 2—152—5 = (302—297) &c.
Winding C 3—153—6 = (303—297) &c.

From the foregoing three formulæ 3, 4 and 5, it follows that for all series windings of this type where the re-entrancy is equal to the multiplicity (*i.e.*, where the winding consists of so many electrically separate simplex windings) we may develop the general formula :

$$\text{Commutator pitch} = \frac{U \pm M}{p} = MN \quad \ldots\ldots\ldots \quad (6)$$

Where M = the multiplicity (*i.e.* = no. of pairs of circuits).

Unequal Multiplicity and Re-entrancy.

We have next to consider the type of winding in which the multiplicity and re-entrancy are not equal. Fig. 4 illustrates a duplex singly re-entrant series winding (◎). It will be seen that this winding is very similar to the duplex doubly re-entrant (○ ○) in that in $\frac{P}{2}$ spans the winding covers the whole of the segments plus or minus 2. The essential difference, however, is that, after advancing along segments 1, 3, 5, &c., it reaches segment 2 and proceeds along the segments of even number, finally re-entering at segment 1). This is due to the fact that the commutator pitch is one less or more than a multiple of two, so that after passing through one half of the units the winding, instead of closing on itself at segment 1, passes to one beyond that point and thus reaches segment 2 and the remainder of the segments, finally closing at segment 1.

Similarly in the retrogressive example given in Fig. 4 the winding, starting at segment 1, recedes two segments after

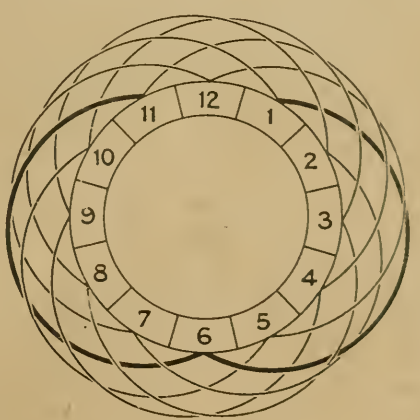

Fig. 4.

passing through $\frac{P}{2}$ units, its passage round the commutator being as follows :

1—6—11—4—9—2—7—12—5—10—3—8—1

For all duplex singly re-entrant series windings (◎) it follows :

$$\text{Commutator pitch} = \frac{U \pm 2}{p} = 2N \pm 1 \quad \ldots\ldots\ldots\ldots \quad (7)$$

Example (*g*). A four-pole duplex singly re-entrant series progressive winding contains sixteen units.

$$\text{Commutator pitch} = \frac{16+2}{2} = 9 \; ; \; (N = 5) = \text{Step of } 1—10$$

The winding will connect to the commutator in the following order :

1—10—3—12—5—14—7—16—9—2—11—4—13—6—15—8—1.

Next consider what happens at the commutator of a triplex singly re-entrant series winding (◎◎). This is very similar to the triplex trebly re-entrant winding (○ ○ ○) for again in $\frac{P}{2}$ spans the winding covers the whole of the segments plus or minus 3, but here, again, the commutator pitch has to be

one less or more than a multiple of 3 so that the winding may advance from the one set of segments previously associated with winding A to those in winding B and so from those to winding C.

Hence for triplex singly re-entrant series windings :

$$\text{Commutator pitch} = \frac{U \pm 3}{p} = (3N \pm 1) \quad \ldots\ldots\ldots\ldots \quad (8)$$

Example (h). A four-pole triplex singly re-entrant progressive series winding contains nineteen units.

$$\text{Commutator pitch} = \frac{19+3}{2} = 11 \; ; \; (N=4) = \text{Step of } 1\text{—}12.$$

The passage of the winding round the commutator will thus be as follows :

1—12—4—15—7—18—10—2—13—5—16—8—19—11—3—14—6—17—9—1.

It will be seen that for multiplex, singly re-entrant series windings the commutator pitch must not be a multiple of M, otherwise the winding would close after one tour and so result in a winding where $M = R$. It will also be seen later that the commutator pitch must not contain a factor (greater than unity) of M, otherwise the winding will not be singly re-entrant. We may, therefore, say that for all multiplex series windings where $R = 1$, and is less than M :

$$\text{Commutator pitch} = \frac{U \pm M}{p} = MN \pm B \quad \ldots\ldots\ldots\ldots \quad (9)$$

where B is a whole number (usually 1) not containing a factor of, and less than, M.

Multiplex Winding.

We have finally to consider the multiplex winding where R is greater than 1 but less than M; (◎ ◎ ; $M=4, R=2$); (◎ ◎ ◎ ; $M=6, R=3$); (◎◎ ◎◎ ; $M=6, R=2$) ; &c.

These are the most complicated to deal with, but upon analysis they will be found to be simply combinations of two or more similar sections, each of which may be expressed by formula 9. That is to say the commutator pitch for any winding of this final type is simply a multiple of the commutator pitch for one of its separate sections.

Example (i). Consider a quadruplex doubly re-entrant series progressive winding for a four pole armature containing ninety-six units (◎ ◎ ; $M=4, R=2$). This winding will be seen to consist of two similar sections, each of which is a duplex singly re-entrant (◎), winding with forty-eight units.

For either section, *in terms of its own segments only* we may therefore say :

$$\text{Commutator pitch} = \frac{48+2}{2} = 25 = (2N \pm 1 \text{ as per formula 7}).$$

But as there are two sections to the winding interspaced in the core and commutator (*i.e.*, the one section connecting to all segments of odd number and the other to those of even number, just as in the case of the duplex doubly re-entrant (○ ○) winding, the only difference being that each section is now a duplex singly re-entrant, instead of a simplex winding), it follows that as the number of segments and units is doubled the pitch must also be doubled. This will easily be understood if the winding is imagined as consisting in the first place of one section only, a certain unit having its ends joined to segments a pitch of twenty-five apart, the commutator then being opened out to receive the segments of the second section. As the number of segments is now twice as great it follows that the distance between any two segments has been doubled, consequently the segments to which the unit is joined are now a pitch of fifty apart.

For the combined (◎ ◎) winding, therefore, in terms of the *total segments* in the commutator :

$$\text{Commutator pitch} = \frac{96+4}{2} = 50 = 2\,(2N \pm 1) \quad \ldots\ldots\ldots \quad (10)$$

The windings will connect to the commutator in the following order :

Winding A. 1—51—5—55—9—59—13, &c. ..... (1)
Winding B. 2—52—6—56—10—60—14, &c. ..... (2)

From the foregoing it follows that the general formula for this final type, where R is greater than 1 but less than M, can be easily developed from formula 9, which gives the pitch for any separate section.

Since R = number of separate sections, U = total segments in the commutator, and M = total multiplicity, we may say that for any one section in terms of its own segments only :

$$\text{Commutator pitch} = \frac{\frac{U}{R} \pm \frac{M}{R}}{p} = \frac{MN}{R} \pm B \text{ as per } \ldots\ldots\ldots \quad (9)$$

Therefore, for the combined winding, consisting of R sections :

$$\text{Commutator pitch} = R\frac{\left(\frac{U}{R} \pm \frac{M}{R}\right)}{p} = R\left(\frac{M}{R}N \pm B\right) \ldots\ldots\ldots \quad (11)$$

$$= \frac{U \pm M}{p} = MN \pm RB \ldots\ldots\ldots\ldots \quad (12)$$

where B is a whole number not containing a factor of, and less than $\frac{M}{R}$.

We thus see that all multiplex series windings fall under one of two classes, (a) those consisting of one or more simplex singly re-entrant windings, and (b) those consisting of one or more multiplex singly re-entrant windings. The commutator pitch in each case is simply R times the pitch for one section. It is for this reason that in formula 9, B must not contain a factor of M in order that $R = 1$.

For suppose that the commutator pitch for a sextuplex singly re-entrant ($M=6, R=1$) series winding were to be :

$MN \pm 2$ or 3 ; (*i.e.* B containing a factor of M)
$= 6N \pm 2$ or 3.

But this may be expressed

(a), 2 $(3N \pm 1)$ or (b), 3 $(2N \pm 1)$,

which means that in (a) the winding would contain two sections each of which would be a triplex singly re-entrant, or as in (b) three sections each a duplex singly re-entrant (see formula 7). Hence it follows that B must not contain a factor of M.

Three Simple Rules.

We have thus reduced the commutator pitches to three simple rules which may be usefully summarised :

1. Where $M = R$ (○) ; (○ ○ ○), &c. :

$$\text{Commutator pitch} = \frac{U \pm M}{p} = MN \quad \ldots\ldots\ldots \quad (6)$$

2. Where $R = 1$ and is less than M (◎) ; (◎◎◎) &c. :

$$\text{Commutator pitch} = \frac{U \pm M}{p} = MN \pm B \quad \ldots\ldots\ldots \quad (9)$$

3. Where R is greater than 1, but less than M (◎◎ ◎◎) ; &c.

$$\text{Commutator pitch} = \frac{U \pm M}{p} = MN \pm RB \ldots\ldots\ldots \quad (12)$$

From all of which it will be seen that the greatest factor common to the commutator pitch and the multiplicity is equal to the degree of re-entrancy ; which fact may be expressed as

A Fourth and Final Rule.

4. The G.C.F. of Y and $M = R$, where Y = commutator pitch.

It will also be seen that in each case the commutator pitch is :

$$Y = \frac{U \pm M}{p}$$

Where U = Total units = total segments in commutator.
M = Multiplicity = Number of pairs of circuits.
p = Pairs of poles.
R = Re-entrancy = Number of electrically separate sections.
N = Any whole number.
B = A whole number (usually 1) less than, and not containing a factor of $\frac{M}{R}$

It will thus be seen that for any type of series drum d.c. winding of any degree of multiplicity or re-entrancy, the commutator pitch may be easily expressed in terms of segments by a simple formula for which it is necessary to know nothing beyond the number of segments in the commutator and the type of winding.

The Sea Return Impedance of a Submarine Cable.

By JOHN R. CARSON and J. J. GILBERT,
American Telephone and Telegraph Company and Western Electric Company.

The transmission characteristics of a conducting system, such as a submarine cable circuit, are determined by its propagation constant, Γ, and characteristic impedance, K, which may be calculated for the frequency $p/2\pi$ from the formulæ :

$$\Gamma = \sqrt{(R+ipL)\ (G+ipC)} \quad \ldots\ldots\ldots\ldots\ldots\ (1)$$

$$K = \sqrt{\frac{R+ipL}{G+ipC}}$$

where R, L, G, and C are the four fundamental line parameters, resistance, inductance, leakance, and capacity, all per unit length of the system, including the return conductor. These formulæ are rigorous for all types of transmission systems ; but the determination of the line parameters is not always possible by elementary methods, and may indeed be a matter of considerable complexity and involve rather difficult analysis.

Effect of Sea Water on Transmission.

It is the practice in submarine cable telegraphy to employ an earthed system, in which the earth and the sea water surrounding the cable are made a part of the cable circuit. It is obvious that even where very low frequencies are involved the return current will not be distributed uniformly through the sea water, but will show a tendency to concentrate in the vicinity of the cable core. This effect, together with the complications introduced by the presence of the armour wires, makes the computation of the resistance and inductance of the "sea return" a difficult problem, and no satisfactory solution is to be found in the literature of submarine telegraphy. There is, therefore, an element of uncertainty introduced into the theory of cable transmission, since the sea return plays the same part as the core conductor and its resistance and inductance are involved in the determination of the characteristic impedance and the propagation constant of the cable.

This uncertainty is not always very serious. In the case of slow speed cables, for example, it is safe to assume that the resistance of the sea return is small compared with the resistance of the core conductor, and that the cable inductance has a negligible effect upon transmission.

Where Exact Information is Necessary.

There are many cases, however, where these assumptions do not hold and where exact information regarding the resistance and inductance of the sea return is desirable. In duplex operation, for instance, unbalance disturbances of a certain type are encountered due to failure to correct, in the artificial line, for the inductance and resistance of the sea return at frequencies much beyond the transmission range of the cable. Also, in the case of telephone or high speed telegraph cables the sea return impedance becomes a very important and even controlling factor in transmission, and this fact has led to a modification of cable design, so that cables of this type are furnished with conducting sheaths composed of copper tape laid on the cable core, which provide a low resistance path for the return current.

The writers have made a study of this problem as part of an investigation* of submarine cable transmission, in connection with the research programme of the American Telephone and Telegraph Company and the Western Electric Company, the object being, not only to develop methods of predetermining cable characteristics, but also to furnish a theoretical guide for analysing the effect of the various factors involved, for interpreting and supplementing experimental studies, and thus to furnish a basis for a sound and economical design of the cable.

Mathematical Difficulties.

In taking up the analysis of the propagation of alternating currents over a submarine cable, the problem was first simplified by replacing the armour wires by a continuous iron sheath concentric with the core. This appeared to be a reasonable approximation that would not introduce any serious errors, and in fact it has been made in every prior study of the problem. This assumption facilitated the mathematical analysis, since, in the simplified structure, everything is symmetrical with respect to the axis of transmission. The mathematical solution offered no difficulties beyond those of computation, which were considerable, because of the facts that the solution involved Bessel functions and that the investigation was extended so as to include the effect of metallic sheaths in addition to the armouring. The main feature of this preliminary study is, that by introducing directly the engineering concepts of linear resistance, inductance, capacitance and leakance it was possible to express the solution in the usual engineering form. As a consequence, the formulæ admit of considerable direct interpretation without computation, and it is possible to determine directly the impedance of the group of conductors, including the sea water, which constitutes the path for the return current. This is of advantage, inasmuch as prior studies along similar lines, such as those of J. J. Thomson, leave the analysis in such shape as to require considerable further work to reduce the formulæ to a form suitable for engineering calculations.

The results of the calculations based on this preliminary study in which the armour wires are replaced by a continuous sheath showed that the effect of this sheath was so surprisingly large, even at moderate frequencies, as to make the simplifying assumption of very doubtful validity. For example, in one calculation it was found that at a frequency of less than 36 cycles per sec., 90 per cent. of the return current was carried by the sheath, and at 100 cycles per sec. the return current was completely excluded from the sea-water, which, therefore, played no part in the electrical system. These effects were accompanied by a pronounced increase in attenuation.

Effect of the Armour Structure.

These results made it evident that in order to arrive at a reliable solution a more thorough analysis of the problem was essential, with particular reference to the actual structure of the armour. The simplifying assumption regarding the armour wires was abandoned, and the general problem was attacked, in which the armour wires were taken as they actually exist on cables, and no special assumptions were made regarding their geometry or their electrical properties. This greatly increased the analytical difficulties, since the structure lacks the circular symmetry which was the essential simplifying property in the previous solution, and it was found necessary to develop several novel mathematical methods in order to arrive at a solution.

Concentration of Return Current.

Numerical solutions, obtained by this general method, of a number of problems involving existing types of cable and their possible modifications have furnished a considerable fund of information which throws much light on the phenomena of cable conduction and is of great value in transmission studies. As may be seen from Tables I and II, the return current shows a decided tendency, even at comparatively low frequencies, to crowd in towards the core and thus concentrate in the innermost of the group of return conductors. In these particular instances the innermost conductor was the armour sheath, and the effect of seemingly slight changes in the structure of the armouring can be seen by comparing the results in the various cases.

Table I.—*Percentage of Return Current carried by Armour Telegraph Cable.*

Frequency p.p.s.	Armouring.	
	Continuous Sheath.	Wires.
25	84	9
50	96	17·5
75	99	25
100	100	31·5

Table II.—*Percentage of Return Current carried by Armour Wires Seattle-Sitka Cable.*

Frequency p.p.s.	Structure of Armouring.	
	Open	Closed
100	43·0	55·0
200	61·0	75·0
300	79·5	82·5
400	73·5	86·5
500	76·0	88·5
600	77·5	91·0

Since the armour wires are of high impedance it would be expected that large values of return resistance would result ; and such is

* See "Transmission Characteristics of the Submarine Cable," John R. Carson and J. J. Gilbert. Journal of the Franklin Institute. vol. 192, p. 705. December, 1921.

the case, as may be seen from Tables III and IV. In fact, these results indicate that the return resistance would be reduced to a small fraction of its value in the range from 25 to 100 cycles if the iron armour wires were removed from the cable.

In a similar manner, it can be shown that if a thin copper sheath be interposed between the core and the armour wires of the cable

Table III.—*Resistance and Inductance of the Sea Return.*

Frequency p.p.s.	Armouring. Sheath. Res. ohms/km.	Sheath. Ind. mh./km.	Wires. Res. ohms/km.	Wires. Ind. mh./km.	None. Res. ohms/km.	None. Ind. mh. km.
25	0·74	4·00	0·075	1·90	0·025	2·25

100	1·49	2·50	0·450	1·51	0·100	1·75

it would tend to carry the major portion of the return current as the frequency increased. This would result in a considerably diminished return resistance, on account of the low resistance of the sheath compared with the armour wires. This improvement is

Table IV.—*Resistance and Inductance of the Sea Return Seattle-Sitka Cable.*

Frequency p.p.s.	Resistance ohms/km. Open	Resistance ohms/km. Closed	Inductance mh./km. Open	Inductance mh./km. Closed

400	1·06	1·25	0·88	0·98
500	1·16	1·35	0·82	0·95
600	1·25	1·45	0·80	0·91

especially noticeable in the audio and carrier ranges of frequency, and in fact conducting sheaths are an essential feature of cables designed to transmit such frequencies.

Theory and Practice Agree.

As a check of the method, calculations of the resistance and inductance of the Seattle-Sitka cable were compared with the results of measurements made upon that cable. Considering the error involved in measurements of this sort, the check between theory and experiment is remarkably good. A further comparison was made of the return resistance at 3 000 and 10 000 cycles per sec., employing measurements made by the American Telephone and Telegraph Company upon the Vancouver cable. The results are shown in Table V. Here, again, there is good agreement between

Table V.—*Resistance of Return Conductor ohms/mi Victoria-Vancouver Cable.*

Frequency p.p.s.	Computed.	Experimental.
3 000	2·87	2·92
10 000	4·45	4·60

the measured and calculated values; and it is safe to say that the method which has been described is exact for all frequencies which are likely to be transmitted by submarine cables.

The conclusions that have been drawn as a result of this study are: (1) The resistance of the sea return of a submarine cable is by no means negligible, even at low frequencies, and it has a considerable effect upon transmission; (2) the resistance and inductance of a cable are greatly dependent upon the geometrical arrangement and the electrical properties of the armour wires; (3) the return resistance at high frequencies can be decreased by providing the cable with a thin metallic sheath in electrical contact with the armour wires.

In addition, the method furnishes rigorous formulæ for computing the resistance and inductance of cables with structures of various degrees of complexity, and indicates the modifications that must be made in the methods of cable design in order that the elements of the cable external to the core may function efficiently as part of the conducting system of the cable.

High-Power Mercury Arc Rectifiers.

At a recent meeting of the North-Western Centre of the Institution of Electrical Engineers at the Engineers' Club, Manchester, the subject of "Mercury Arc Rectifiers" produced a most interesting informal discussion. Mr. R. L. Morrison, who introduced the subject by a very able paper illustrated by lantern slides, outlined briefly the theory of operation and the various difficulties encountered in commercial manufacture,* the chief of these being probably that of constructing an arc chamber, which must be both accessible and absolutely gas-tight. It is claimed that this difficulty has been completely overcome by the invention of the mercury seal, but the fact remains that a mercury vapour pump for maintaining the vacuum is still the indispensable first of a number of auxiliaries necessary for working these installations efficiently.

A Multiplicity of Second Cousins.

This "multiplicity of second cousins," as Mr. A. G. Ellis humorously described the auxiliaries, received, together with other features of the apparatus, a good deal of adverse criticism. Mr. H. A Ratcliffe, who opened the discussion, suggested that the object of the meeting was to gain information on a new subject, and perhaps the best method of obtaining this from the manufacturer was by criticism of his product. Criticism certainly was keen, and Mr. Morrison, who said he had been warned that the Manchester meeting would be "a hard nut," found his arguments and figures assailed on all sides. Mr. Ratcliffe doubted whether the rectifier could substantiate any claim on the grounds of price, space or simplicity. Price figures were not given, the space necessary was not small. The simplicity, he thought, was questionable. In reply, later, Mr. Morrison said that the price of a rectifier installation would be somewhat higher than that of rotary converter equipment and with auxiliaries included the space needed might also be a little more. In answer to other questions, Mr. Morrison explained that the efficiency figures claimed were overall efficiencies, from high-tension a.c. to d.c. busbars, thus including auxiliaries. The comparative weights given, however, did not include auxiliaries.

Rectifier and Converter Efficiencies.

Mr. R. Townend claimed that the maximum efficiency, 90 to 92½ per cent., attributed to the rotary converter was too low; 93 to 93½ per cent. was often attained, and efficiency much below this would not have much chance in competitive markets. He thought the power rectifier was good in its simplest form, as for a 2-wire system of fairly constant load where fine voltage regulation was not essential. This granted the rectifier a field of service in high voltage traction work, but for lighting services there would be additional expense of automatic regulators. In reply to questions, Mr. Morrison gave the natural regulation of power rectifiers as 12 per cent., which could be reduced to 4 per cent. by the use of a suitable cathode coil. The addition of an automatic regulator would allow regulation of 1 per cent.

The necessity of providing a transformer of so much higher power than the output of the rectifier set provoked some criticism. Taking the output of the rectifier as 100 the power of the attendant transformers was stated to be 135 for three-phase, 155 for six-phase, and 184 for twelve-phase.

Use in Automatic Sub-Stations.

The question of suitability of rectifiers for automatic sub-stations received a good deal of attention. Mr. Morrison had mentioned that a rectifier resuming operation after some hours of inaction might need from 12 to 15 min. working of the vacuum pump, and this possible delay was quoted by several speakers as a serious objection. In reply, however, it was stated that a recently developed electrical system of vacuum indication and pump control would enable the plant to be kept ready automatically for immediate operation at any time. Many other points were dealt with, of which, perhaps, the most important was the behaviour of rectifiers in the event of short circuit.

The general tendency of opinion was to admit the probable usefulness of rectifiers for certain kinds of traction work. Mr. Paxton emphasised several points in this connection, especially the absence of flashing at heavy loads and the advantages resulting from the elimination of magnetic circuits from converting apparatus. One disadvantage quoted by several speakers was the non-reversible nature of the rectifier, which renders it unable to co-operate in schemes of regenerative braking. For this reason an installation for the French Midi railway included 16 1 200 kW rectifiers and 4 1 200 kW rotary converters, the latter for purposes of regeneration.

The power rectifier has undoubtedly made an impression, and in spite of the keen criticism of some of its claims there was a marked desire to consider this new development with an open mind and to remember, as Mr. Morrison pointed out in his reply to the discussion, that the apparatus has scarcely yet emerged from the "teething troubles," having but some five years of development as against the twenty-five of its competitor, the rotary converter.

* See The Electrician, Jan. 2, 1920, p. 10.

Radioactivity.

(*Concluded from page* 413.)

In the second three of a series of six lectures which Sir Ernest Rutherford, Cavendish Professor of Physics at Cambridge, delivered before the Royal Institution, the properties of the members of radioactive families were dealt with, and it was pointed out that the study of radioactive disintegration had forced the idea of isotopes upon us. Methods of detecting radioactive discharges were described and the determination of nature, velocity and radioactive heat dealt with. In the final lecture a concise account of recent developments was given.

Dealing in his fourth lecture with the properties of the members of the radioactive families, Sir Ernest Rutherford pointed to the peculiar differences in the characters of successive members. Radium, a metal of distinct chemical affinities, gave emanation, an inert gas. Was there any order in these changes and any connection with the chemical properties of ordinary elements? Radioactivity was an atomic property, and we had to consider the structure of the atom. An atom, it was now established, resembled the solar system. The mass was concentrated in the nucleus, the diameter of which was yet very small compared with the diameter of the atom. That diameter was determined by the rings of electrons surrounding the nucleus. An electron was simply an atom of negative electricity, and in the neutral atom the sum of the negative charges balanced the positive charge of the nucleus. In the case of oxygen we had 8 electrons, 2 near the nucleus, 6 in a ring further out, and the positive charge was 8 units. That charge, or the number of electrons, determined the whole properties of the atom. Hydrogen had one unit charge, helium 2, lithium 3, and so on, to uranium, the heaviest known atom, with 92 units. These numbers were the Moseley or atomic (ordinal) numbers. The whole structure was held together by the forces between the positive and negative units; the properties would also depend upon the distribution of the charges, but the lecturer did not propose to deal with that. The nuclei of certain atoms, though having the same nuclear charge, or excess of positive over negative electricity, might yet differ as to nuclear mass. All the atoms of that element would then have the same properties, in spite of their different mass, and these bodies were called isotopes; chlorine had such an isotope, and mercury had several.

Radioactivity and Isotopes.

The study of radioactive disintegration had forced this idea of isotopes upon us. In the changes α, β, or γ particles were expelled, and they came from the interior of the nucleus, which must itself therefore be of a complex structure. The α particles were atoms of helium, carrying each two positive charges; the β particles were electrons; the nucleus therefore must contain both helium and electrons and be a little world in itself. The resultant nuclear charge was the excess of the positive charge over that of the electrons. In the subjoined diagram, Fig. 6, the number

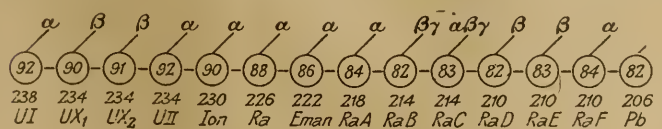

Fig. 6.

within the circle expresses that resultant charge or ordinal number, as determined by X-ray analysis, and the number underneath is the atomic weight or mass. Uranium UI had the mass 238·2 and the ordinal number N = 92. By losing an α particle or atom of helium of mass 4, it turned into UX_1 of mass (238 − 4) = 234 and number N (92 − 2) = 90, because the UI had lost 2 unit charges. UX_1 lost one β particle of very small mass, only 1/1845 of the mass of an α particle; hence that loss could be neglected. UX_2 (the new product) had mass 234, but its N was 91, by 1 greater than 90, because the loss of one electron increased the resultant positive charge by one unit. UX_2 again lost a β particle in passing into U II; the mass therefore still remained 234, but the N rose once more by unit back to 92.

When U II next changed into ionium, an α particle was lost; the mass therefore decreased by 4 to 230, and the N by 2 to 90. With U II we had thus come back to U I as to the resultant charge, but not as to mass, and these two bodies were isotopes, bodies which—as had been proved in other cases—could not be separated by chemical means. With the next change we came down to radium, Ra, mass 226, N = 88; both these figures had been confirmed by analysis and by X-ray study respectively. The last member of this family was lead, called radium-lead, in order to distinguish it from ordinary lead. As the successive changes from uranium to this lead involved the loss of 8 α particles, the mass of radium-lead should be 238 − 4 × 8 = 206; but ordinary lead had the atomic weight 207·2.

Changes in the Thorium Family.

Sir Ernest then traced the similar changes through which the members of the thorium family passed, leading finally to a thorium-lead, which, accepting the evolution outlined, ought to have an atomic weight 208. When actinium was also considered, and all the radioactive members were tabulated together, the possibility of many isotopes was at once apparent. When it was observed that ionium and thorium had the same properties and were inseparable, and that similarly radium and mesothorium should be the same, except for a difference in their radioactive properties, Russell, Fajans, and Soddy simultaneously suggested in 1913 the generalisation that the loss of one α particle would take an element by two steps down the periodic table, in which the elements were arranged in the order of their atomic weights, and that the loss of one β particle would raise it by one step. Thus elements might both come down or be raised to positions already occupied by other elements; hence the name "isotopes." The suggestion naturally appeared strange to chemists. But as regards the end-products mentioned, the experimental confirmation was striking.

These experiments were particularly difficult because in the radioactive minerals uranium and thorium were generally mixed. The thorite found in very ancient rocks of Ceylon was fairly free from radium, however, and the relatively younger pitchblend of Joachimsthal contained very little thorium. From these minerals Soddy and Hönigschmid had independently isolated two kinds of lead of the following properties, differing from ordinary lead:

Ordinary lead	atomic weight	207·19	density 11·337
Radium lead	,,	206·08 (206)	,, 11·280
Thorium lead	,,	207·9 (208·12)	

the figures in brackets being the masses calculated according to the theory of radioactive disintegration.

Further, ordinary thorium had an atomic weight 232·12; thorium from pitchblende gave 232·5, probably because it contained some ionium. Ordinary lead might be a mixture of the two lead-isotopes; but it might also have an origin of its own. With regard to further possible elements and isotopes, elements of the atomic numbers N = 43, 61, 75, 85, and 87 were still unknown, whilst one of the numbers 81, 82, 83, 84 was represented by as many as 8 isotopes; lead had 7 isotopes, thorium 5, radium 3.

Detection of Discharges.

Coming to the numbers of particles discharged, Sir Ernest remarked that each α particle passing through its limited range of air surrounded itself with a cylinder of ionised molecules; but the electric change so produced was just on the verge of detection. The way to magnify the effect had been shown by Townsend. In their first experiments on these lines Sir Ernest and H. Geiger had made the α particle enter through a small bore an exhausted vessel in which a high potential difference was maintained between an axial wire (connected to an electrometer) and the walls of the vessel; any ion was thus speeded up; it ionised other molecules, and thus magnified the effect thousands of times. With, say, four particles entering per minute the counting of the electrometer deflections was, however, very laborious. Geiger therefore made the apparatus photographically recording with the aid of a string electrometer consisting of a silvered quartz fibre or a very fine Wollaston wire or string (used in the demonstration). The string was joined to the axial wire at one end and earthed through a

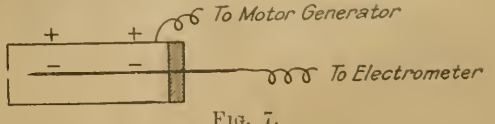

Fig. 7.

very high resistance at the other; it was vertically stretched between the plates of a condenser, and was bodily deflected (shifted to right or left) each time a particle entered. In the final form the axial wire (a polished needle) faced with its sharp point the small opening in the tube, which had the size of a thimble (Fig. 7). The needle was connected to the string electrometer. In the demonstration the tube was charged to 1 400 V from a

motor generator. The source of the α radiation was a speck of polonium on a foil, the frame of which was slowly pushed up to the hole in the box. The range of those α particles was 3·86 cm., and when this approach was reached the string began to kick. Then the polonium was replaced by thorium, which gave α particles of a range of 8 cm., and the kicking began at that larger distance; in both cases all effects stopped when a piece of paper was interposed between the source and the box. The numbers of particles thus counted were not constant; the kicks did not succeed one another at regular intervals, and sometimes two were almost simultaneous; the number was subject to the laws of probability. A gram of radium alone, free of other radioactive

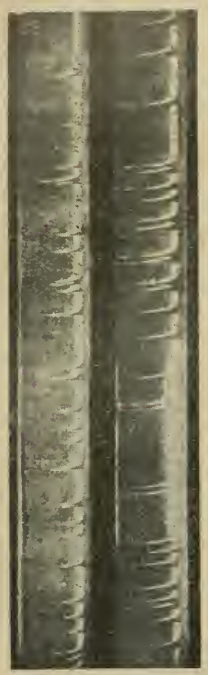

Fig. 8.

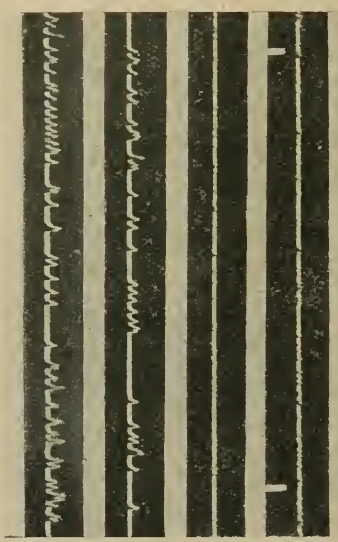

Fig. 9.

materials, would give $3{\cdot}6 \times 10^{10}$ α particles per sec., and when that amount of radium was in equilibrium with the other products, the number would be 4 times greater. Figs. 8 and 9 illustrate the kicks due to α and β particles.

Another way of demonstrating the α particles was to put a speck of radium on a fine needle and touch the photographic plate with the needle for a short time; the developed plate then showed the

Fig. 10.

splash of Fig. 10 (highly magnified), in which each ray represented the path of one α particle through the grains of the plate emulsion.

Detection by the Scintillation Method.

In the fifth lecture Sir Ernest Rutherford stated that the number of α particles could also be determined by the scintillation method of Crookes. Each α particle hitting a screen of zinc sulphide (the sulphide was dusted on a glass plate) produced a very intense flash lasting only 1/40 000 of a second. In order to make the microscopic field of these observations large, Messrs. Adam Hilger had constructed a peculiar-looking microscope which gave a field of view of 40 sq. mm., on which up to 25 α particles might fall per minute. The counting of these scintillations was a very trying operation, even when the eye had first been rested in the dark for half an hour, and since the emission of the particles was governed by the law of chance, many countings had to be made to arrive at a fair average; the error varied as the square root of the number of observations.

In the method of determining the numbers of particles due to C. T. R. Wilson the particles were sent through air saturated with moisture, which they ionised. On passing through moist air an α particle from Ra C (range 7 cm. in air at ordinary pressure) would produce 235 000 pairs of ions, each of which might serve as a nucleus for the condensation of water vapour in tiny drops. Those drops were very crowded in the case of α particles, and less crowded when β particles were used; the former gave a straight track, the latter a crooked track. In another photograph exhibited a trace of emanation had been put into the moist air; the α particle track looked remarkably straight and long (though the real length was only $\frac{1}{8}$ mm.), and the track showed the recoil of the air molecule from which it had started at its origin.

Determination of Nature and Velocity.

The nature and velocity of the particles had since 1903 been determined, for some years with little success, by experiments on their deflection by electric and magnetic fields. In magnetic fields the deflection depended upon the velocity u of the particle, in electric fields on u^2, and in both cases also on the mass of the particle m. The particle was made to hit a photographic plate; if deflected first upward and then, by reversing the field, downward, the particle would describe two curved paths and strike two spots, the distance between which would represent twice the deflection; from that the E/m, the ratio of the charge on the particle to its mass, could be deduced. These experiments were very much more difficult with α particles than with β particles or kathode rays, and the deflections for the α were very small, unless fields 10 000 times the intensity of those required for kathode rays were used. Yet Geiger and Rutherford had found that range R of the α particle varied approximately as the cube of its velocity u, so that $u^3 = kR$. Any screen interposed in the path of the α particle reducing its velocity u by $\frac{1}{2}$ would reduce the range R by $\frac{1}{8}$. By such experiments with very intense fields they had found that for α particles the E/m was 4 823 electromagnetic units. If the α particle were, as we believed, an atom of helium carrying two electric charges, the ratio should, from electrochemical considerations, be ·4 826, a very striking agreement. From experiments with RaC (yielding α particles of range 7 cm.) Rutherford and Robinson had deduced $mu/E = 3{\cdot}985 \times 10^5$, or $u = 1{\cdot}922 \times 10^9$ cm. or roughly 20 000 km. per sec. From this velocity and the Geiger u^3 rule, the velocities and energies of the other particles of known ranges had been determined for the members of the uranium series.

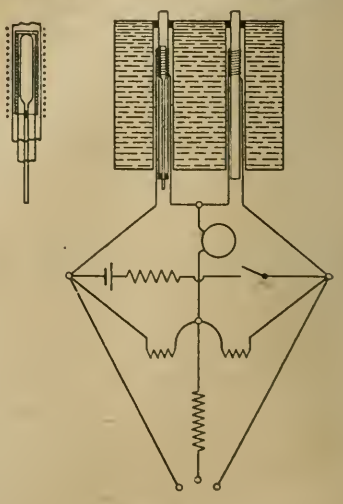

Fig. 11.

Radioactive Heat.

Passing to the heat continuously given out by radioactive bodies, Sir Ernest mentioned that the first measurements of Pierre Curie and A. Laborde had been made in 1903 with the aid of a Bunsen ice calorimeter. The calorimeter shown in Fig. 11, used for Sir Ernest's demonstration, was more suitable. Two equal fine platinum spirals (resistance thermometers) wound on glass tubes formed two arms of a Wheatstone bridge; the source of heat was placed inside the one tube, and the other tube was surrounded (see small diagram of Fig. 11) by a compensating coil through which a current was sent to balance the deflected galvanometer of the bridge. In order to prove that this evolution of heat continued at the low temperature of liquid air and was independent of the surrounding temperature, Sir Ernest made use of the method of Sir James Dewar, who measured the amount of liquid oxygen (within a Dewar vessel) vaporised by the respective body or

radiation; the rate of liberation of oxygen for oxygen remained unchanged, as the radium salt used (once cooled) remained in the apparatus during the course of the lecture.

Shares of the Rays in Heat Evolution.

With the aid of the above-mentioned electric calorimeter and the radium deposit collecting on the wall of emanation tubes (previously referred to) it was possible to apportion the shares which the α, β, and γ rays had in the heat evolution. The emanation was drawn off and condensed; the Ra A decayed quietly, and after about 30 minutes, when the heat curve dropped strongly, practically only Ra C would be left. The γ rays finally remaining could be absorbed by lead, though that would require 6 in. of lead, and so H. Robinson and Sir Ernest had arrived at the following table of heat effects in gram-calories per gram of radium per hour:

	α	β	γ	Total.
Radium.....	25·1	—	—	25·1
Emanation ..	27·6	—	—	27·6
Ra A.....	30·5	—	—	30·5
Ra B+C....	39·4	4·3	6·5	50·2
Total	123·6	4·3	6·5	134·4

Thus 1 gram of Ra in equilibrium with its descendants would liberate 134·4 gram-calories. The figures showed that the α rays contributed the main share of the kinetic energy; the observed heat effect of Ra C seemed, however, to be a little too small, and that was an interesting problem. That the α particles were really charged atoms of helium had been known long before these determinations of the E/m. Each gram of Ra gave $1{\cdot}36\times10^{11}$ α particles per sec., or $4{\cdot}28\times10^{18}$ α particles per year; the cub. cm. of helium contained $2{\cdot}74\times10^{19}$ atoms, and the gram of radium should then give 158 cub. mm. of helium (at normal pressure and temperature) per year. Similarly uranium gave $2{\cdot}75\times10^{-5}$ cub. mm. of helium per year, thorium 3·1, and uranium mineral in equilibrium 11, all expressed in 10^{-5} units. In some compact minerals of ancient formations the helium accumulated, not being able to escape; carnotite, which was not compact, and the relatively young pitchblende, contained little helium, whilst 1 gram of samarskite (very old mineral) contained 1·2 cm³ of helium per gram. Sir Ernest demonstrated the evolution of helium from pitchblende by heating this mineral strongly in a quartz tube and leading the gas into a spectroscopic tube after condensing all the gases present, except helium, by charcoal.

Recent Developments.

Opening his last (sixth) lecture, Sir Ernest remarked that he had intended to refer to the conclusions which the helium contents of minerals enabled us to draw as to their ages. But he would rather speak of recent developments in the study of β and γ rays. The β rays were very swift electrons; the γ rays highly penetrating X-rays. We could work discharge tubes at potentials of 150 000 V, but it would take two or three million volts to produce electrons of β ray speed and energy, and the energy equivalent to that of the α rays would require forces of four million volts. Using the string electrometer and the pointed-needle tube (with hole) as before, Sir Ernest showed that the β rays from radium D strongly deflected the electrometer, but not when the magnetic field turned the β particles off. When the source was held in such a position that the particles could not pass directly through the hole there was no deflection; but when a plate of some metal (aluminium) was held like a mirror so as to reflect the particles roughly in the right direction, deflection was at once observed again, because the β particles were easily scattered. A lead plate reflected better than aluminium. In the further experiments, the source, 6 mg. of radium, was held several feet away from the electrometer, and the effect was yet very strong—too violent almost for the instrument, in fact. A screen of aluminium interposed in the path of the rays weakened the effect; but some particles penetrated even through 2 in. of lead.

The Nuclear Structure of the Atom.

This last effect now was not due to any direct β or γ particles of the radium, but to secondary β particles released in the lead by the γ rays from the radium. The same effect, though very much weaker, was known in X-ray experiments. The γ rays passed right through the 2 in. of lead and caused the ejection of swift β rays from the far surface of the block. The primary β rays could not force their way right through that thickness of lead, and if the secondary rays had come directly from the lead surface, they would have the same speed as the primary β rays; if they were excited at some depth within the metal, their speed was smaller. What was the wave-length of these highly-penetrating γ rays? To answer that question we had to consider the nuclear structure of the atom, and these recent studies had enabled us to investigate the nucleus of the heavy atoms which we had so far been unable to attack. The nucleus was supposed to be surrounded by successive rings (not necessarily circular) or shells of electrons, known as the K, L, M, N rings (see Fig. 15, to be explained presently). A β particle shot out from the nucleus might occasionally collide with an electron, *e.g.*, in the K ring, and drive it out. But the external (ring) system would rapidly return to its former state, we believed with Bohr, and pick up an electron from outside which, in falling back into position, would emit radiations characteristic of that particular K ring. Thus we should anticipate occasionally to observe, in addition to the characteristic radiation (in this case the K radiation), a much more penetrating nucleus radiation. Prof. Rutherford came back to this point at the end of his lecture.

Sorting the γ Rays.

In order to sort out γ rays, Rutherford and H. Richardson placed, within a box mounted in a magnetic field, some Ra B and C behind one or several absorbing screens of aluminium and allowed the radiation to enter an electrometer chamber filled

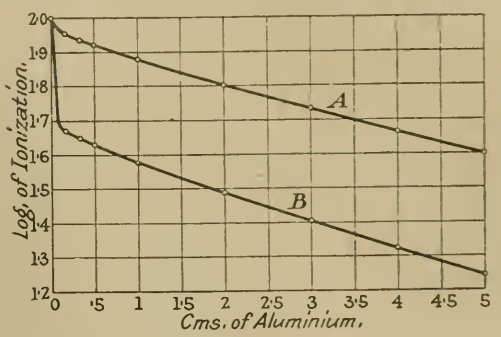

Fig. 12.

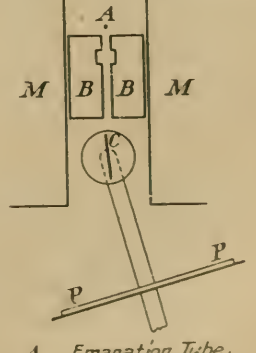
either with air or with a heavier vapour, methyl iodide. Curves A (air), Fig. 12, and B (methyl iodide) showed in both cases, but particularly in B, an initial drop indicating first a rapid absorption, and then a steady diminution in the rate of absorption, though not quite the same diminution in the two cases. By these means three components of the γ rays were distinguished, of absorption coefficients 230 cm.$^{-1}$, 40 cm.$^{-1}$, and 0·51 cm.$^{-1}$, the last being the most penetrating rays. The former two coefficients were also the characteristic M and L radiations of lead which, it was noteworthy, was not known at that time to be an isotope of Ra B. The smallest coefficient found for γ rays from Ra C was 0·115 cm.$^{-1}$. Wave-length measurements were made with the aid of the apparatus illustrated in Fig. 13, representing a modification of Bragg's X-ray method. The source, an emanation tube, was at A, the B were blocks of lead, and C was the crystal of rock salt, mounted on an arm which supported the photographic plate PP; the whole was placed between the powerful electromagnets MM.

Arrangement for γ-Ray Spectrum.



A. Emanation Tube.
BB. Lead Block.
C. Crystal.
MM. Electro-Magnet.
PP. Photographic Plate.

Fig. 13.

The long exposures required, a day or more, were apt to fog the plates, and some of Sir Ernest's early photographs of 1903 showed only two distinct strong lines (others less distinct) at deflections of about 12 deg. and 10 deg. But these and other lines were found by the later work of Siegbahn and Friman to agree exactly with characteristic X-ray lines of lead. The agreement was not quite so good for the more penetrating γ rays, reflected at almost grazing incidence, down to 42 minutes of arc and corresponding to a wave-length of $0{\cdot}71\times10^{-9}$ cm. The method was not suitable for measurements at still smaller angles, and the spectrum was evidently very complex, as we might expect from the fact that experiments with X-rays at about 100 000 V could only give us the low-frequency range of radiations, whilst the shortest γ rays would require potentials of 2 000 000 V or more for their excitation.

β Ray Spectra.

Passing to β ray spectra, Prof. Rutherford said that, with the arrangement of Fig. 14, where S was the source of the rays fixed

within the wide slit of a thick block of lead, and PP a photographic plate, all in a strong magnetic field, the γ rays would shoot up up in a conical pencil, whilst the β rays would be bent off in circular paths, the wider, the swifter the particles. When the source was Ra F, which gave few γ particles, the spectrum was practically continuous; when Ra B C were used, in which γ rays were prominent, bands could be distinguished in the β spectrum, and these bands (the strong lines of Fig. 15) arose from the conversion of γ rays into secondary β rays (previously spoken of) by the collisions between γ rays and the shells of electrons surrounding the nucleus. For this conversion the quantum relation held: $E=h\nu$. But some energy, ω, would be expended in removing the electron from its position in the shell, and the equation should therefore be within $h\nu\gamma=E\beta+\omega$.

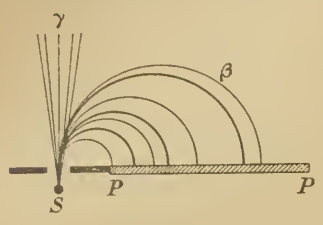


Fig. 14.

When the source was an emanation tube placed in a lead cylinder (or wrapped with foil), most of the β rays would be stopped or scattered, but the γ rays would be able to pass, and they would

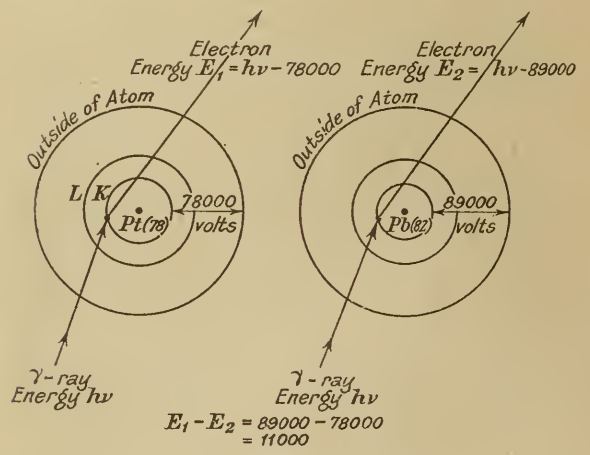

Fig. 15.

generate secondary β rays yielding diffused bands, sharp on their high-frequency side and diffused on the other; the sharp edge would correspond to the swiftest rays from the outer lead surface, the diffused edge to rays from inner layers.

Change in Absorption Spectra.

The absorption spectra changed with the metal through which the γ rays were shot (the cylinder material). Sir Ernest showed some photographs referring to cylinders of tungsten, platinum, lead and uranium. Each spectrum consisted of a rectangle, dark black on the left and less dark on the right, and the edge of the dark portion receded more and more to the left in the order stated. That showed that β particles from the lighter metals* travelled more swiftly than particles from the heavier metals. The relations would better be understood from the two atoms, one of platinum, one of lead, in Fig. 15. In both cases a γ ray of frequency ν collided with an electron in the K ring; to remove that electron required (as we knew from X-ray experiments) 78 000 V for Pt and 84 000 V for Pb. The energy with which the β ray would emerge from Pt, *i.e.*, the $(h\nu\gamma-\omega)$, would hence be $(h\nu-78\,000)$, and in the case of Pt it would be $(h\nu-89\,000)$, that is, the energy would by 11 000 V be less in the case of the heavier element; in other words, the particle lost more energy in escaping from the element of greater mass.

Energy of the γ Rays.

Modifying the arrangements of Fig. 14 in such a way that the particles of the same speed were brought to the same focus, C. D. Ellis had found last year in the Cavendish Laboratory that each of the four heavy metals just referred to gave 3 strong lines in the β ray spectra, of the following energies (in 10^5 V): tungsten W (atomic number 74): 1·66, 2·20, 2·76; Pt (78): 1·58, 2·12, 2·69; Pb (82): 1·49, 2·03, 2·60; U (92): 1·22, 1·74, 2·31; some of these lines had previously been determined by de Broglie. If each of these lines were excited by a γ ray, as Prof. Rutherford had suggested, the energy of the respective γ ray should be greater than the above figure by the energy required to remove the respective electron from the atom; these removal-energies ω were known from the X-ray work of Siegbahn, and they amounted to: W 0·693; Pt 0·762; Pb 0·891; U 1·178. Adding these ω terms to the first figures, we obtained for the 3 lines: W 2·35, 2·89, 3·45; Pt 2·36, 2·91, 3·46; Pb 2·38, 2·92, 2·49; U 2·40, 2·92, 3·79, that is to say, the same γ energies for each of the three lines of the four elements. That proved that the various secondary β rays observed were really excited by three γ rays coming, not from the respective metal, but from the radioactive source.

Deduction of Wave Lengths.

From the energies of the γ rays the frequencies ν and hence the wave-lengths could be deduced by the Planck relation, and in this way Ellis found that the whole of the six β rays (three faint lines, in addition to the three strong ones spoken of) could be accounted for by six γ radiations ranging in wave-length from 0·0 519 down to 0·0308 Ångström unit. Now the energy relations were also known from other researches, and it was thus possible to calculate in which regions, rings, or levels in the atoms the β rays originated. The first of these levels (Figs. 15 and 16) was the K ring; instead of the single L ring indicated in Fig. 15 we had, from Sommerfeld's work on the fine structure of the spectrum lines, to assume three levels, that made the 4 levels above zero level 0 marked by the numbers 1, 2, 3, 4, 5 in Fig. 16. The drop from 5 to 1 would cause the emission of a ray of energy $4{\cdot}025\times10^5$ V; the drop from 4 to 1 would correspond to 3·636, and so on; there would have to be γ rays corresponding to these transitions, and rays of those respective energy differences had actually been measured by Rutherford and Andrade in 1914, as the following figures showed:

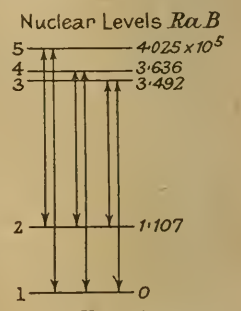

Fig. 16.

Origin 5 to 4	energy 0·389	λ calculated 0·318	obs. 0·324	Å. U
5 to 3	0·533	0·231	0·229	
7 to 3	0·144	0·857	0·853	
2 to 1	1·107	0·112	0·115	

Another noteworthy relation had been pointed out by Ellis. The six γ lines from Ra B consisted, as mentioned, of three strong lines and three weak lines. When we tabulated their energies in pairs like this

4·000	3·639	3·492
2·918	2·529	2·385
1·082	1·110	1·107

we saw that the difference between the strong and the weak line of a pair was constant. That should be so if the drop was not from 5 to 1, but from 5 to 2, *e.g.*

The Origination of Gamma Rays.

Finally, Sir Ernest came back to the question why we believed these γ rays to originate in the nucleus and not perhaps in the space between the innermost K ring and the nucleus. The two isotopes, Ra B and lead, of atomic number 82, were identical also as to the K and L rings, and Ra B emitted the full K and L spectrum of a body 82 (Rutherford and Andrade). If the γ rays were emitted previous to the actual disintegration of the Ra B nucleus, the atomic number should be 83. That there were, in lead, no electrons inside the K ring was proved by bombardment experiments; since Ra B differed from lead only as to the constitution of the nucleus, that argument of Ellis would also apply to Ra B, and the γ rays must hence come from the nucleus. There was then strong evidence, Sir Ernest remarked in concluding, that we had a system of very high-frequency oscillations inside the nucleus, as well as the system of electronic oscillations outside the nucleus with which Bohr had dealt. For these reasons experiments with the highest possible discharge potentials had become so desirable, and he hoped that we should, in the course of a few years, advance considerably beyond the million volts of the most recent experiments.

Mr. G. R. Crowe assisted in the demonstrations.

* Sir Ernest's terms "light and heavy" do not refer to density, but to atomic weight; the atomic weights of the four elements are, W=184, Pt=195, Pb=207, U=238; the densities are in ascending order, Pb=11·3, U=18·7, W=19·1, Pt=21·5.

Counterbalancing the Slump.

The Electricity Supply Authorities' Opportunity.

By W. A. GILLOTT, A.M.I.E.E.

In many districts, the industrial areas in particular, the central station engineer views with mixed feelings the lessened output due to slackness of trade, lock-outs, &c. It is evident that some measures must be taken to improve present conditions, and place us in a better position should these unhappy circumstances recur at a later date. Industrial troubles and fluctuations are ever present; therefore, a profitable load that is stable under practically any condition is to be desired and fostered. Such a load is waiting at the door of every central station, and by proceeding in the right direction it can be connected to the mains, and will bring a substantial reward. I refer to domestic electrification.

Many authorities have, and some still do, look upon the domestic load with indifference, thinking it not worth while. This is a great mistake, and I repeat, as on many previous occasions, that with a well-planned campaign and the "will to do," the domestic load can be made to reach the proportions of a moderate industrial load. Difficulties! Of course, there are difficulties, what "worth while" object is reached without meeting obstacles. If one cannot jump over them, one must go round or under them so long as the other side is reached.

Realising there are various matters to adjust, plans can be made to meet them. Let us take the case of cables, this being, in all probability, the most difficult matter, as many existing networks in the residential areas were laid out for lighting. In the very bad cases there is no other alternative than strengthening. But why delay?—it must be done some day. Prices will not fall to such a degree that it will pay to lose the load awaiting this problematical time. Experience teaches that it is advisable to extend cables gradually to meet this class of business; the increased revenue will provide capital for further extensions.

Diversity of Electric Cooking Load.

It is extremely doubtful, however, if all the districts of any undertaking, particularly the large ones, are overloaded, and a good deal of the fully loaded networks are only apparently so. Cases have arisen in the writer's knowledge where certain networks were stated to have reached saturation point, but wishing to connect new load, many hundreds of kilowatts of cooking were added without strengthening the cables or meeting trouble. Why? Because electric cooking load is of high diversity. There is a certain village where over 200 6 kW cookers are installed, yet the maximum load on the feeders at any one time does not exceed 120 kW, this demand occurring at a time when the central station needs the load, *i.e.*, midday. There are many instances of this nature, but those given will suffice for the moment. Station capacity very seldom enters into the question, as this is usually adequate for immediate needs.

The Question of Cookers.

What of the cookers, how are these to be disposed of—sold, hire-purchased, or hired? This, of course, depends upon local conditions. If load is rapidly required, hiring should be adopted. These powers are given to all undertakings in the 1919 Act. If slower progress is desired, cookers may be hire-purchased, and if the district permits it, and still more moderate progress is the order, selling only should be adopted.

If it is decided to secure load quickly cookers should be supplied by simple hiring. Substantial and reliable cookers for families of four to six persons can be obtained in reasonable quantities from £9 to £12 each, rentals from 30s. to 40s. per annum are a sound proposition. The maintenance is not very serious; on a number, 100 or over, it will average approximately 10s. to 12s. per cooker per annum. Certain cooker manufacturers are prepared to support electricity supply authorities by offering maintenance schemes which, to a large extent, relieve the authorities of anxiety. This is a step in the right direction. Upon this basis the rental pays the maintenance costs and returns roughly 10 per cent. upon the outlay. Not this, however, but increased consumption is the direction in which substantial gain should be looked for. From careful observation, extended over a long period, it is found that the electric cooking load provides a return of approximately 320 to 350 kWh per annum per kW installed. Therefore, taking as an illustration, a station with 500 6 kW cookers on the mains, this will account for roughly 1 000 000 units per annum, the *M.D.* being approximately 300 kW amd *off peak*. The greatest advantage of the cooking load, however, is in the fact that slackness of trade and industrial troubles do not materially effect it, as people must eat, and it is the electricity supply industry's business to see that as many people as possible eat food cooked by electricity. Compare this load with a works providing an *M.D.* of 300 kW, when a strike or lock-out occurs, and the whole load is lost until the difficulties are settled. We cannot afford to proceed along these lines, as it allows too much capital to lie idle.

Result of Cultivating the Domestic Load.

If we inspect the load curve of an average gas works it will be found that Sunday's load is, in the majority of cases, heavier than any week day. This is a result of cultivating the domestic load. A similar condition cannot yet be expected in the electricity station, but there is no reason why a start should not be made to bring about such a tendency. It will not cost the householder more to cook electrically than by his present method, providing, of course, tariffs are designed to stimulate progress, and this being one of the essential features there should be no doubt about it. The restaurants, hotels, &c., also offer a good proposition, and it is worth the effort to secure their business.

No doubt, the question passing through the minds of my readers is, how are we to secure this business? By carefully planning the district, concentrating upon its development by practical demonstrations in the showroom and the home, the free use of suitable literature from E.D.A., the "will to do" and showing the courage of our own convictions by employing electricity freely in your own home, as an encouragement to others.

Briefly these are the outlines to follow. Every supply authority, however small, could add a little to its mains and, even if only for experience to base future developments upon, let a start be made. It's worth while.

An Interesting Type of Switchgear.

A correspondent who has recently visited "Jaarmarkt," Utrecht, Holland, gives some details of a number of outdoor sub-stations for the 10 000 V system installed in that district. The system covers

Fig. 1.—A Small Outdoor Sub-Station.

a fairly large area and the cables are run to feeder points, where a three-unit switch allows a branch cable to be taken off and any of these cables to be connected or disconnected. About forty of

Fig. 2.—The Switch Ready for Operation.

these small self-contained sub-stations are in use in the district, some in buildings, but the majority are simply placed by the roadside in the splendidly wooded neighbourhood.

The arrangement employed seems to be entirely rainproof, and many of the pillars are erected with a simple wrought-iron cover, which must be removed before the switches can be worked, but most of them are housed in neatly-designed pillars allowing the handles to be exposed as soon as the door is opened. There is room in the pillar for a testboard and a telephone. It is stated that automatic devices can, if desired, be fitted to the switches. We understand that this gear is not only popular in Holland, but also in Belgium

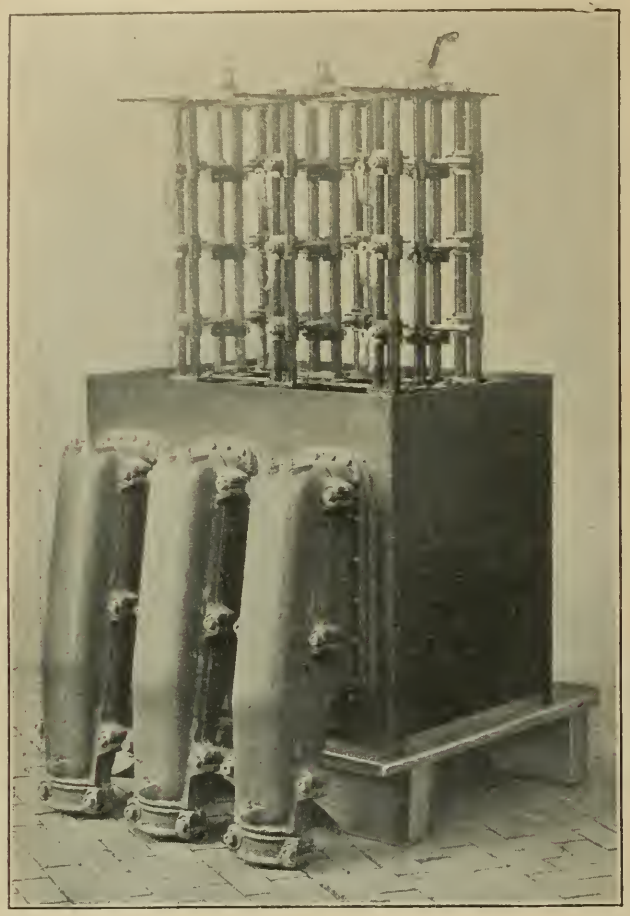

Fig. 3.—A "Close Up" of the Switch Used.

and Denmark, and in all there are about one hundred of these sub-stations in use.

The makers claim that the cost of this gear is so reasonable that it will be employed where, up to now, the expense of a building has made a project impossible.

From the illustrations it will be seen that each switch is fitted with three cable sealing boxes, where the three three-phase cables are brought in. Inside at the back of the tank are fixed three busbars, to which the three cables are connected through the three pole switches, the unit is therefore a complete sub-station in itself. Five-unit switches and single-unit switches are also standard, and the gear is made up to 10 000 and 20 000 V. Fig. 1 shows one of the simple switches by the roadside. Fig. 2 shows a similar switch with the cover lifted, ready for operation; and Fig. 3 gives some further details.

Miners' Blindness.

The committee recently appointed by the Medical Research Council to inquire into the causes and prevention of miners' nystagmus have published a first statement of their findings. They are unanimous in the opinion that the CHIEF CAUSE OF THE DISEASE IS DEFICIENT ILLUMINATION, due to the low illuminating power of the safety lamps generally used by coal-miners, and they recommend that everything possible should be done to make the standard of illumination of the objects looked at by the miner equal to that of an open-light pit by greatly increasing (to about two or three candles) the illuminating power of safety lamps as ordinarily used, or by the use of an electric light capable of being fixed on a miner's head, belt, or other convenient position, so that the light is automatically brought nearer the working area and does not impair clear vision by shining directly into the eyes. Such a lamp, in fact, has lately been perfected by Mr. F. J. Turquand, of Turquand & Kew, and we propose to give full details of it in a subsequent issue.

Correspondence.

CHANGING TUNGSTEN TO HELIUM GAS.

To the Editor of THE ELECTRICIAN.

Sir,—Apropos of the note on "Changing Tungsten to Helium Gas," in the issue of THE ELECTRICIAN of March 17, 1922, p. 322, it may be interesting to quote one paragraph of my Vice-Presidential address, delivered at the Columbus, Ohio, meeting of the American Association for the Advancement of Science, in August, 1899, and published on p. 778 of the issue of THE ELECTRICIAN of Sept. 22, 1899. The statement quoted follows a consideration of electric furnace temperatures.

A superior limit is, however, already set for us by the vaporization of all known substances, no materials for lining the furnace being available, not subject either to fusion or vaporization, thus using up the energy which would otherwise go to increase the temperature. A suggestion as to a possible extension of temperature range may be made here. It may be requisite to work with closed receptacles under pressure, and to discharge through them electric currents of so great energy-value as to attain almost instantaneously the highest temperatures, to be maintained for only a very short time. We may imagine a huge condenser charged to a potential of, say, 10 000 V as discharged through a limited body of gas contained in a small space within a strong steel tube which has a lining of refractory non-conductor. The energy may thus possibly be delivered so suddenly to a very limited body of material as to result in a momentary elevation of temperature passing all present known limits and capable of effecting profound changes in molecular constitution. We need all possible extension of the limits of research in this direction in order to discover some clue to the relations which the chemical elements bear to each other. The limit of possible strength of the containing receptacle, or some unforeseen factor, would probably set the new bounds. The point to be here enforced, however, is that far beyond any increase of working range in temperature obtained in any way, there must still exist a further range unattainable by our best efforts and possibly for ever outside of the field of experimental research. Our knowledge of this higher range can alone be derived from a study of the actions going on in the stars and nebulæ.

It may be interesting, also, while on the subject, to call attention to the fact that very early in the history of electricity, very heavy condenser discharges were produced and known, and a special instance of which was the production of the so-called "Tylerian" machine used by Van Marum, and well known to the students of the early stages of our science. It is recorded, in connection with this machine (which was a large example of the plate type frictional) that the battery used by Van Marum with the machine consisted of 100 jars, each 13 in. in diameter and 2 ft. high, the total coated surface of which aggregated 550 sq. ft. It instantly deflagrated small iron wires 25 ft. long, and vaporized various metals placed in the path of the discharge. Blocks of hard wood 4 in. square were split into fragments. This is interesting as probably the first instance of the use of a large capacity discharge.—I am, &c.,

West Lynn, Mass., April 11, 1922. ELIHU THOMSON.

A Metallurgist on the Electric Furnace.

Mr. F. Rowlinson, lecturing on the present and future scope of the electric furnace in the manufacture of tool steel before the members of the WEST YORKSHIRE METALLURGICAL SOCIETY recently, said that it was no exaggeration to say that the electric steel furnace had had, and would have, as great an influence on the metallurgy of steel as had the processes of Huntsman, Bessemer, Siemens, Martin, and Thomas. In this country at least the electric furnace was at present under a cloud—more particularly because of the high cost of energy, because of unsatisfactory work turned out by half-trained operators who had not the experience in electric steel that the old-timers had in other processes, and chiefly because of the extravagant claims of some of the pioneers. It was still true that quality of the finished steel depended mainly upon the ingredients put into it, and not on what was refined out of it. The old crucible steel-makers, therefore, chose their materials from the best in the world—the best steel-making Swedish irons, the best Sheffield blister bar, every piece hand-fractured and graded, the best Swedish white irons, and the best Sheffield tool scrap. To this day the finest tool steel in the world—Sheffield crucible steel—was made only from the most expensive materials of unquestioned purity and quality. Comparing conditions in the electric tool-steel industry, the lecturer said the electric furnace was a superb refining agent. Material of only moderate purity was charged, and a steel was produced which on analysis and in appearance was exactly equivalent to the best crucible steel. But trial soon showed that it was deficient in quality. It lacked that indefinable "body" possessed by a high-class crucible steel. The claims that the electric furnace could be charged with any old scrap, provided it was steel, and that by clever chemical manipulation and elaborate refining a tool steel of the finest quality could be produced, had done incalculable harm. The electric furnace could produce tool steel equal in every respect to the finest crucible steel, but the necessary precautions must be those taken in the making of crucible steel.

Electric Traction in South Africa.

A White Paper issued by the Government of the Union of South Africa contains reports on the ELECTRIFICATION OF THE NATAL MAIN LINE by the General Manager of Railways and Harbours (Sir Wm. Hoy), and by the consulting engineers (Messrs. Merz & McLellan), together with estimates of cost, annual charges for working and maintenance, &c. In our issue for December 9 last we were able to announce that the Government had decided to proceed with the electrification of the Pietermaritzburg-Glencoe section, and at the same time we gave some particulars of the engineers' proposals.

In his report Sir Wm. Hoy supports Messrs. Merz & McLellan's recommendation to start with the section from Glencoe Junction to Pietermaritzburg (a distance of 171 miles), instead of the Durban-Pietermaritzburg portion, and he also endorses the view that the best means of improving the capacity of the Natal main line is by electrification. The line north of Pietermaritzburg is very congested, and relief is urgently needed, but the section between Durban and Pietermaritzburg is not so urgent, and it can be undertaken when financial considerations permit.

Duplication No Remedy.

The duplication of the railway north of Pietermaritzburg would enormously increase the capacity of the line, but it is not a remedy for present difficulties. Electrification would give practically the same relief as doubling and in as short a time as if the latter remedy were chosen, and, in addition, electrification offers the advantages of improved working conditions and reduced operating costs. Messrs. Merz & McLellan estimate that the electrification of the Pietermaritzburg-Glencoe Junction section would save £237 510 a year in working expenses, compared with steam traction. The cost of electrifying the section on the basis of a down load of 30 000 tons gross per day is estimated at £4 453 690, with a liberal margin for development. During the four months of last year which showed the highest traffic movement, the average traffic carried in a downward direction over the busiest section of the main line was only 18 369 tons gross per day. It will, however, be possible, over short periods, to carry a greater tonnage than 30 000 tons per day, and the power station will be designed so that it can be readily extended as required.

Sir William Hoy thinks it inadvisable to purchase locomotive equipment to deal with more than 20 000 tons at the outset, and new electric locomotives can be ordered as required. The locomotives that will be ordered will be able to deal with a greater traffic over short periods. This reduction in the number of locomotives reduces the cost of locomotives, plus contingencies, to £1 005 000 and the total expenditure to £4 183 000. Provision is, however, being made for the full scheme so that additional locomotives may be obtained as required.

The power station will be equipped to meet the industrial as well as railway requirements. It is thought that the power station and transmission lines will be taken over by the proposed electricity authority in the Electricity Bill, which will be introduced into Parliament this session. By providing for an industrial load the Administration (or the electricity authority) will be able to supply current along the route of the railway and at Pietermaritzburg for municipal and industrial purposes. The site of the power station has not yet been determined, but it will be conveniently situated in relation to the section of line to be electrified and to possible future expansion. If the power station and transmission lines (estimated to cost £1 534 690) are taken over by the electricity authority, and as locomotives would have to be purchased in any case, the total additional capital cost to the administration of the electrification scheme will be £1 643 310.

Branch Lines to be Electrified.

When the proposed electrification is finished, other sections, such as that from Glencoe Junction to Tendega and from Durban to Pietermaritzburg should also be electrified. The sections Glencoe Junction to Pietermaritzburg and Glencoe Junction to Tendega are the only sections on which, in the absence of electrification, traffic developments will entail heavy expenditure in the near future on track improvements beyond those already in hand. The Glencoe Junction—Tendega line is ideal for electric traction. If development continues on this section at the rate at which it has been proceeding recently, relief will be needed at a comparatively early date, because of the heavy grades and the difficult conditions of working under steam traction. The estimates provide for electrifying both tracks between Pietermaritzburg and Merrivale and a single track beyond to Glencoe Junction, except for the short length of double track between Ladysmith and Daimana Junction, and the proposed double track between Umbulwana and Ladysmith. A double track is not a necessity for through traffic under electrification, and, except where parallel doubling already exists, the old route between Pietermaritzburg and Merrivale will not be used except for local traffic. It cannot be abandoned because of the vested interests and residences that have grown up around it. The old line can, however, be lifted between Merrivale and Nottingham-road and between New Leigh and Estcourt, though the latter should be retained for a time as a safeguard against further landslides or washaways on the new line. The Nottingham-road—Merrivale improvements had to be taken in hand in view of the delay in proceeding with electrification.

Advantages of Electric Traction.

There are numerous tunnels on the Natal main line which render electric traction necessary, and with electric working the liability to grass fires will cease. When the main line is electrified, it will be possible (Sir Wm. Hoy thinks) to equip at a comparatively small expense some of the more important and difficult adjoining branch lines. Overland coal for the Cape Province has to be sent *via* Volksrust—Germiston—Fourteen Streams whenever the traffic exceeds a certain tonnage, owing to the difficulty of working trains over the Van Reenen Pass. The time-table load for a coal train up the Pass is 300 tons with a branch line Mallet. If the line over the Pass were electrified it would simplify and considerably cheapen through working between Natal and the Orange Free State. On the Greytown branch difficulty has been experienced from time to time in working the traffic. This line is heavily graded, and if traffic continues to expand, it will be necessary to spend large sums in re-location and regrading. This line could be electrified at comparatively small expense, and the cost of re-location and regrading saved. The Cape—Natal line is a very expensive line to work, because of severe grades and curves, and the advisability of electrifying it should be investigated. The short Howick branch (2½ miles in length) could be electrified very cheaply as no sub-stations would be required. This line is very expensive to work under steam, and it should be electrified as part of the present scheme. The cost is comparatively small, about £7 500.

Delays through derailments and engine failures would be avoided by electric traction, and other advantages would also accrue. In addition, the national aspect of electrification is very important. The industrial advantages will also be great. Electrification will provide all along the railway a trunk electrical line, from which power can be distributed for industrial and other purposes. It will also open up great possibilities for by-product production at the power stations from waste coal; and Sir William Hoy recommends that Messrs. Merz & McLellan be asked to consider the advisability of designing the power station so that the necessary plant can be added for by-product recovery as soon as practicable.

Electric Safety Lamps.

The "VAG" ELECTRIC SAFETY LAMP has been approved for use in all mines, subject to the conditions set out in the Order of March 31. Including the lamps in the present list, there are now twenty-six approved lamps for general use and thirteen for use by officials or for special purposes only.

The "Vag" miners' electric safety lamp comprises: (1) An accumulator case of pressed steel, lead lined and strengthened by transverse ribs. A steel ring at the top of the case provides a bayonet joint for attachment of the cover. (2) A two-cell accumulator, with casing of celluloid or of ebonite with celluloid top, for use with either (*a*) semi-solid electrolyte, or (*b*) liquid electrolyte; in the latter event it is fitted with a device for preventing the escape of liquid whatever the position of the lamp, whilst allowing for the release of gases. The terminals are of the spring-plunger type, and the capacity of the accumulator is 4·5 Ah with a voltage drop to not less than 3·6. (3) A cover or lantern, which can be attached to the case by a bayonet joint. The lantern carries a lampholder with dome-shaped reflector mounted on a disc of ebonite or other non-inflammable insulating material, in which are embedded contact pieces of brass, which make electrical connection with the terminals of the accumulator. The lampholder is held in position by a bayonet ring. The lamp-bulb is protected by a dome-shaped cover-glass, with four steel pillars and a steel crown piece. The current consumption of the bulb is 0·45 to 0·5 A. (4) A magnetic lock.

Approval is subject to the further conditions:—(i) That the total weight of the lamp is not more than 6 lb. 10 oz. (ii) That the strength of material and attachments throughout the lamp is not less than in the samples submitted for official test. (iii) That the lamp shall be capable of maintaining a light of not less than 1 c.p. all round in a horizontal plane for not less than nine hours, and also of giving a light of not less than 1·5 c.p. over an arc of 45° in a horizontal plane. (iv) That the lamp has been made at the "Venta" Accumulator Works (Leipzig). (v) That the integral parts of each lamp shall have marked upon them the name or distinguishing mark of the lamp; and that the case shall also bear the name of the maker.

Lamps for Special Purposes.

The following electric safety lamps have been approved for use by officials, or for special purposes only:—

The "Wefco" officials' electric hand lamp (Watts, Fincham, & Company, Ltd.) has an alkaline accumulator with a steel casing and fixed spring terminals. The current consumption of the bulb is 0·95 A, and the lamp is capable of giving 1·5 c.p. over an angle of 45° in a horizontal plane for nine hours.

The "Ceag" bull's-eye lamp No. 2 ("Ceag" Miners' Supply Company, Ltd.) is a modification of the "Ceag" electric lamp bull's-eye type, and the specification of that lamp applies generally, except that the case is shorter, and the accumulator is therefore shorter and of smaller capacity. The capacity of the battery is not less than 4·5 Ah, with a voltage drop to not less than 1·9 V, and the current consumption of the bulb is not more than 0·5 A.

The "Ceag" bull's-eye lamp, type 3 ("Ceag" electric torch), is intended to be used in conjunction with another approved lamp capable of maintaining the required light during the required number of hours.

The Miners' electric hand lamp, type H 1 (Patterson & Company) comprises a cylindrical accumulator case of cast aluminium screwed at the top to receive the cover; a cover or lantern of aluminium, containing the bulb-holder and contact-plate. The current consumption of the bulb is 0·50 A. There is a two-volt lead-acid accumulator, with celluloid casing, so constructed as to prevent escape of liquid whatever the position of the lamp whilst allowing escape of gases. The capacity of the accumulator is not less than 5 Ah, with a voltage drop to not less than 1·8 V. A lens is held by a screw from within the cover, and a lead plug lock is similar to that approved for Pattersons' miners' electric safety lamp, type G 1.

Stonework Cubicle Gear at Southport Power House.

Owing to the increasing demand for electric power in the Southport district considerable extensions were recently made to the Corporation station. In connection with these extensions an order was placed with the General Electric Company for a large quantity of h.t. switchgear to be installed in stonework cubicles, two 500 kW rotary converters, together with the necessary synchronising panels and d.c. switchgear for these machines. The h.t. switchgear was

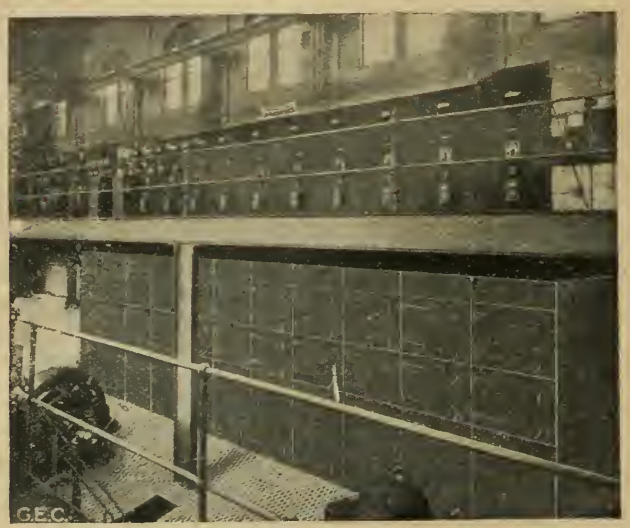

Fig. 1.—General view of 6 600 V G.E.C. cubicle Switchgear and Mechanical Remote Control Operating Board.

required for the control of three 3 000 kW turbo-alternators, the h.t. side of the transformers supplying the two 500 kW rotary converters, three 1 500 kW, and two smaller feeders. The voltage of the apparatus was 6 600, and, as already indicated, the busbars, isolating links, instruments, transformers, oil switches, &c., were accommodated in stonework cubicles. These were erected in a semi-basement, the oil switches being operated from a mechanical remote control board

Fig. 2.—Interior view of cubicle controlling h.t. side of Transformer.

on a gallery immediately over the cubicles. A good idea of the arrangement can be obtained from Fig. 1, which also shows part of the rotaries in the foreground, and the rotary switchgear on the left of the control board.

Isolation Arrangements.

In accordance with the general practice for this type of switchgear the cubicles were divided into compartments by stonework partitions in order to isolate the various units of apparatus to the greatest practicable extent, thereby ensuring the highest possible degree of safety. Thus, the top compartment contains the busbars, this compartment being sub-divided by stonework slabs so that each bar is in a separate cell. Immediately below the busbars is a compartment with isolating links, while the two lower compartments contain instrument transformers and oil switches respectively. The above arrangement is clearly shown in Fig. 2, the cubicle shown controlling the h.t. side of the transformers supplying power to one of the rotaries.

A Fume-Tight Insulator.

An interesting accessory used between the various compartments is a special type of fume-tight insulator, which effectively prevents any gas which may be generated in the oil switch compartment, due to a short circuit, spreading to the other compartments. The oil switches are of the G.E.C. type III., with the usual overload trips and time-limit fuses. The speed of break of such a switch is over 10 ft. per second. Careful attention has been given to the mechanical design of these switches, so that they may be able to withstand the heavy stresses set up should a short circuit occur on the system. It should be noted that no porcelain is used in tension. The instrument transformers were made at the G.E.C. Chamberlain & Hookham Works. They are bolted to stout bars fixed in the appropriate compartment. The secondary l.t. connections are run in conduit to the instruments on the control board. The cubicles are protected with strong steel doors, each fitted with a stout padlock.

A slate flat-back type of operating board was adopted. On this is mounted the oil switch operating handles, also the necessary indicating and measuring instruments. Connection is made from the operating handles to the oil switches by a system of bell cranks and levers. The 500 kW rotary converters are of the standard G.E.C. self-synchronising design for reactance control, the d.c. voltage being 500/550 and the speed 1 000 revs. per min. On the left of Fig. 1 is the switchgear for these converters. The G.E.C. patent self-synchronising panel affords an extremely simple method of starting. Only two elementary operations, controlled by a correct sequence device, are necessary. Another valuable point in the starting arrangement is that the main rotary current does not pass through the starting motor, but external reactances are provided on the back of the panel.

We are indebted to Mr. E. Moxon, the Borough Electrical Engineer to Southport Corporation, for permission to publish the information and photographs in this article.

"Heatrae" Fires.

The extensive range of stoves manufactured by Electric Fires, ltd., Norwich, is designed to meet every conceivable requirement, whether it be for the house, hotel, cabin, public hall, factory, or garage. The fires, which bear the trade mark "Heatrae," are manufactured in a modern factory, specially equipped for mass production, and care has been taken to ensure complete standardisation and interchangeability of parts.

A successful effort has been made to break away from the common

Interior of "Heatrae" Boiling Ring.

practice of using a solid mass of porcelain or fire clay as the basis of the heating unit. The body of the "Heatrae" fire-bar is constructed of a metallic alloy. It is claimed that the metal does not tarnish, and materially adds to the working efficiency. Another novel design is an electric boiling ring, the interior of which is shown in the illustration. It is made of steel, with fine cast-iron top grid, and embodies a reflector that increases the heating power.

At the Chapel-street Congregational Church, Southport, on Saturday, a demonstration was given of an instrument known as the Acousticon, which enables the sermon to be heard by persons of defective hearing. It is claimed that, whilst this invention is in general use in America, so far only one other church in Great Britain has had it installed, namely, St. Andrew's, Edinburgh, though one has been fixed at the Lyric Theatre, London. A small microphone is placed immediately behind the Bible desk in the pulpit, and attached to each of the pews in which the receiver is fixed is a miniature switchboard, which may be manipulated so as to strengthen or increase the volume of sound according to the degree of deafness of the user.

Wind-Power for the Generation of Electricity.

The problem of generating electricity by means of wind-power has always been an attractive one, and many attempts have been made to solve it. Some of the reasons that have, however, militated against the more general use of this form of power are that it has been necessary to employ large and expensive slow-speed windmills mounted upon towers of heavy construction, entailing considerable erection costs, and to drive the dynamos by means of gearing, with a consequent loss of power.

While it is true that, providing the wind wheels are of large diameter, power can be obtained with moderate winds, it is necessary for arrangements to be made to stop the machine when the velocity of the wind exceeds 20 to 25 miles per hour to obviate the possibility of wreckage, and also to prevent the storage battery from being damaged by reason of it being charged at a higher rate than that for which it is designed. It has been impossible, therefore, to take advantage of the power available from high winds and gales, which is obtainable from windmills in proportion to the cube of the velocity of the wind, without the great expense of construction of the windmill, battery, and dynamo.

Dynamos of High-Speed Winds.

In order to overcome these disadvantages a system for the generation of electricity by means of AUTOMATIC HIGH-SPEED WIND DYNAMOS has been designed by F. A. Wilkinson & Partners which,

A TYPICAL WIND INSTALLATION WITH OVERHEAD LINE TO BATTERY.

while the output obtainable from the dynamos is not a large one, becomes appreciable when used for charging storage batteries over long periods, the result being exactly the same as that of correspondingly charging a storage battery at a normal rate for a short period.

The general arrangement of the automatic high-speed wind dynamos for battery charging is shown in the illustration. The system comprises a number of dynamos with direct-coupled impellers, mounted upon a tubular crossbar, fitted with a swivel head and wind-direction vane, which causes the impellers always to face the wind.

The improvement, which is a vital one, consists mainly in the employment of a dynamo having a field magnet system, which rotates in the opposite direction to the armature under the agency of its own direct-coupled impeller. This is found, in practice, to result in an output very considerably greater than that obtainable from the ordinary rotating armature dynamo of the same size. The installation is supported by a vertical tube, which may either be sunk in the ground or mounted upon the roof of a building.

Technical Details.

Each dynamo is rated at 100 W, and battery charging is commenced in winds of 15 miles per hour, the output and speed increasing with the velocity of the wind. The dynamos have laminated fields, and are self-regulating for battery charging purposes. They are of the ventilated type and are enclosed in removable steel cases. Ball bearings are fitted to both the armatures and also to the revolving field magnet systems, the lubrication of the machines thus requiring but little attention. To enable the rotating connections of the armature and field magnets to be readily coupled up to the battery, each dynamo is provided with a multiple contact plate and a terminal board, upon which carbon brushes fitted in spring holders are mounted.

A feature of the system is an automatic cut-out which requires no electrical energy for its operation, the connection and disconnection of the dynamo to and from the battery being automatically effected and governed by the velocity of the wind, thus saving some three or four W required by the usual type of automatic cut-out. One of the dynamos of the installation is arranged as a "control" dynamo, and upon its armature shaft is fitted a sleeve free to move in a lateral direction. Mounted upon this sleeve is a contact plate, while a terminal board provided with adjustable contact fingers is attached to one of the end plates of the machine. When the velocity of the wind is sufficient the contact plate is forced against the contact fingers, making the necessary connection between the dynamos and battery, and conversely breaking the connection when the wind falls below a predetermined value.

Tucker Switches,

The switch which we illustrate has recently been placed on the market by J. H. TUCKER. It shows a marked advance upon the type of quick make and quick break switch in which the action relies entirely upon the spring, or which has only an "initial" positive action which may allow the switch arm to be withdrawn from the contacts, but only sufficiently just to clear them without breaking the "arc." Recognising the "necessity" of a complete positive make and complete positive break, the firm, for the past two years, have been engaged on producing a combination embracing these features.

The spring is of the compression type, enclosed in a specially-designed chamber, forming in itself a complete "spring unit." In the unlikely event of the spring breaking, it is still contained within the chamber and continues to function. A direct drive (quite apart from the spring or the spring chamber) is obtained from the switch "dolly" to the contact arm, in such a manner as to cause the latter to travel its full extent in either direction. The switch can consequently be placed in its correct "on" or "off" position, even if the entire spring mechanism is removed.

THE NEW SWITCH.

In addition to the features already mentioned there are many minor improvements in this new switch. The contact clips are specially designed to give even contact to the switch arm, and are of flexible hardened copper, permanently fixed in their correct position by heavy brass clamping plates. To prevent the possibility of arcing across the contacts, an exceptionally high and wide dividing wall of china has been employed. The contacts are placed well away from the switch bridge and cover so that arcing on to any dead part of the switch is impossible.

With the object of obtaining a clear wide break, the cable clamping screw in the terminal has been reversed, so that it is impossible for this to shorten the arcing distance when the switch breaks, as it does not project towards the contacts. The reversing of the screw will also be appreciated by contractors generally, as it gives ample room for manipulation by an ordinary screwdriver without the risk of damaging the china.

Faraday Entrance Scholarships.

As a result of the Entrance Scholarship Examination held at FARADAY HOUSE ELECTRICAL ENGINEERING COLLEGE on the 11th, 12th, and 13th inst., the following awards have been made:—

R. W. Griffin, County School, Beckenham, the "Faraday" Scholarship of fifty guineas per annum, tenable for two years in college, and one year in works.

D. Moody, Central Foundation Boys' School, London, the "Maxwell" Scholarship of fifty guineas per annum, tenable for one year in college, and one year in works.

W. Swindells, Municipal Secondary School, Brighton, an Exhibition of thirty guineas per annum, tenable for two years.

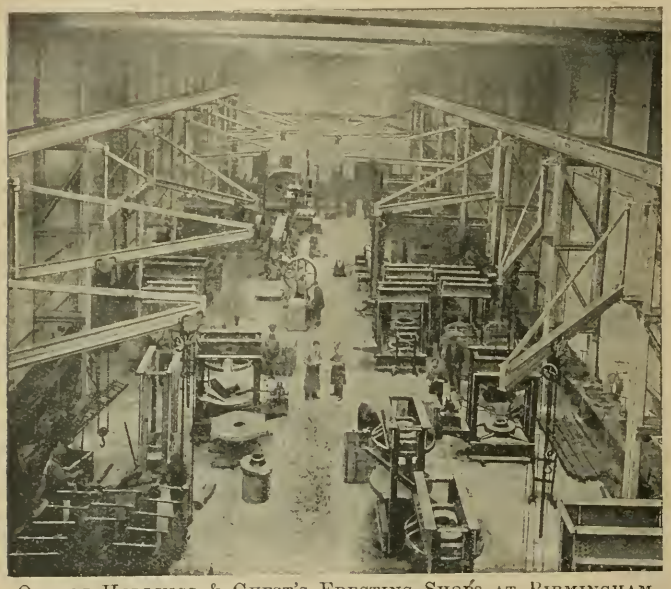
J. K. Watts, Aldenham School, an Exhibition of thirty guineas per annum, tenable for two years.

J. W. Bailey, Elizabeth College, Guernsey, an Entrance Prize of twenty guineas

D. F. Gover, Dulwich College, an Entrance Prize of twenty guineas.

Building Hydraulic Machinery Electrically.

The lay-out and organisation of a modern engineering shop so as to get a maximum of production is a subject of much interest, and we need not apologise for giving some details of a large erecting shop in the works of Hollings & Guest, Ltd., Birmingham. This shop, which we illustrate, is 200 ft. long, and 60 ft. wide. It is well lighted and well equipped for the purpose of dealing with the erection of hydraulic presses, pumps, and accumulators of all kinds in which this firm specialise. The shop is served by a 20 ton electric overhead travelling crane, with an available head room of 25 ft. under the crane. In addition to this the shop is also fitted



One of Hollings & Guest's Erecting Shops at Birmingham.

with fourteen light jib cranes spaced at intervals down each side of the shop, and these cranes are capable of dealing with loads up to 30 cwt. so as to prevent any delay in waiting for the large crane. This ensures that there is no waste of time in the production of the work. The shop is also equipped with a well-laid-out marking-off table of a large size, and also testing apparatus for testing hydraulic cylinders of all capacities and pressure. It is further equipped with a light erecting pit, which can be uncovered in sections for use as required.

A variety of machines in the course of construction can be seen in the illustration. In the foreground are a number of the firm's well-known hydraulic tyre presses, some completely finished, and others partially so. In the centre of the shop can be seen a belt-driven hydraulic pump, and at the far end, towards the left, may be seen another large and powerful press used for joggling plates, as used in the shipbuilding trade. A number of hydraulic girder frame baling presses, of which details have been given in The Electrician, in various stages of progress can also been seen. It may be mentioned that Hollings & Guest, Ltd., specialise in the girder frame type of hydraulic presses, as well as being makers of the old type of four-column press.

One corner of the shop is entirely devoted to the manufacture of gas-heated enamelling stoves, which is an important branch of the firm's activities, and is fitted for this purpose with power-driven punching and shearing machines.

Electric Butt-Welding.

The Whitlock Coil Pipe Company, Hartford, Conn., who for about two years have been employing electric butt-welding for steel and wrought-iron pipe, have found, states the "Times" Trade Supplement, that the time required to make the welds is practically dependent upon the current only, the higher currents requiring the shorter time and also giving the strongest welds.

The cost of a typical butt-weld in 1¼ in. extra-heavy pipe was 15c., including labour, material and energy. By the hand methods formerly employed approximately 45 minutes were required, as compared with an average of 38 seconds when butt-welding with 180 A. Another advantage of this method over arc or oxy-acetylene welding is that the original material is used for making the joint. In a number of tensile tests on butt-welds made at these shops the pipe was torn in every instance before the weld was damaged in any way.

The butt-weld is made by cutting a female scarf in each pipe and then pressing the ends together under an oil pressure of 5 tons while the current is passed through the joint. As the current heats the ends to be welded the scarfed portions are forced outward and the area of the weld is increased over the annular area of the pipe. The inside of the pipe is left smooth and clean without any constriction. The only objection is that the outside diameter of the pipe is increased at the weld, and it is thus impossible to use the pipe in spiral or other coils made on a former which is shaped to fit the ordinary outside diameter of the pipe. Lap welding with a mandrel is employed where it is necessary to obtain a weld without any reduction of the bore or enlargement of the outside diameter.

Country House Lighting Sets.

The design of country house lighting sets seems now to have settled down to well-recognised standards, and it is seldom that any strikingly novel features are developed. But the semi-automatic switchboard which forms part of the set made by the Alden Engine Company has a certain number of features which differ from the usually accepted standard for small plants. Briefly, the sets are made in four sizes, namely model "A," ¾ kW, 25 V, with 120 Ah battery, rated for 30 lights; "B," 1½ kW, 50 V, with 120 Ah battery, 60 lights; "C," 2 kW, 50 V, with 200 Ah battery, 100 lights; "D," 2½ kW, 100 V, with 120 Ah battery, 130 lights.

The engines employed are of the vertical paraffin type, but run at the comparatively slow speeds of 500 to 600 revs. per min., making them suitable for general work in addition to generating. The usual arrangement is a belt drive to the dynamo, though as an alternative the generating sets can be supplied direct-coupled. The capacity of the batteries is at 10-hour rate down to 1·85 V. The glass boxes have open tops, and the plates are Planté type.

The Alden plants are supplied either hand-operated or semi-automatic, the makers favouring the former method; but their semi-automatic board differs appreciably from the usual run of such boards with their rather meagre equipment of instruments, in that it embodies quite as full a range of instruments as a hand-operated board, viz., 3¼-in. dial ammeter (charge), 3¼-in. dial ammeter (discharge), voltmeter, 2-way and "off" voltmeter switch, 6-way regulating switch (charge), 6-way regulating switch (discharge), s.p. dynamo switch and fuse, s.p. lighting switch and fuse, shunt regulator, semi-automatic starting switch.

The illustration shows a 1 kW switchboard which is designed for 50 to 55 discharge V. By its means the following operations can be performed: charging the battery, starting the generating set off the battery, lighting from the battery, simultaneous charging and lighting, direct lighting and power from dynamo.

To start the engine from the battery, both knife switches are closed and the left-hand (charge) battery switch is turned on to the top stud. The starting switch arm is then moved slowly and steadily over the contacts until it is held by the series "hold-on" coil. The dynamo, working as a motor, will now begin to run,

The 1 kW Switchboard.

and when the engine picks up will start to charge the battery. When the battery becomes fully charged the series coil becomes de-magnetised, and allows the starter arm to fly back to the first stud, this arm being fitted with a phosphor-bronze brush, which, when the arm is in the "off" position, locates between and short-circuits two brass studs connected with the magneto.

The overall size of the panel is 21 in. by 16 in., and it is mounted separately upon an angle-iron frame from the floor, not upon the dynamo or engine. Although the range of instruments and the means of regulation on this switchboard are so full, the total price of the set is not increased on this account.

An invention designed to make the detection of fire-damp possible with the electric hand lamp is at present undergoing tests at the Home Office. The invention comprises a small attachment for use with the lamp which enables the user to note the actual amount of fire-damp, which can be easily read from a scale. In the development of the invention there is a device which gives an automatic alarm, either by flashing a signal light or operating a bell or hooter, as soon as the fire-damp reaches a dangerous point.

Legal Intelligence.

Fraudulent Consumption of Electricity.

Gideon George Grieve and Archibald A. Manges, carrying on business as electrical and mechanical engineers at West Bute-street, Cardiff, were charged at Cardiff Police Court on Friday last with laying an electric wire to the Corporation supply main so as to obtain electricity without it passing through the meter, with using such electricity, injuring the meter and the fittings, and with culpable negligence and wilfully injuring the fittings and using the electricity without the consent of the Corporation electricity department.

Mr. Kenvyn Rees, who prosecuted on behalf of the Corporation, stated that defendants made application for a meter to be installed. There was a meter on defendants' premises, and this was connected up and the various fittings and fuses sealed up. The first reading, up to Dec. 8, showed that they used 15 units, on Jan. 15 the metre recorded 64 units, but on Feb. 13 the meter recorded nothing. It was then found that the meter was "blown," and it was evident that defendants had tried to get through the meter more power than it would carry, with the result that the coil burst. The seals on the Corporation fuses had been broken and a fuse, capable of carrying more electricity, had been substituted. A wire had been connected by which electricity could be consumed without passing through the meter. By another wire defendants could get electricity for heating purposes. The men sold electric supply and electric heating apparatus, and it was assumed they had been demonstrating these goods to probable purchasers without paying for the current.

Frederick Geo. Barnard, electrical engineer employed by the Corporation, said the reason the meter burnt out was because an overload of current had passed through it. If consumption had gone on at the same rate as before there would have been approximately £2 worth of electricity used for lighting only, but that did not include any current which might have been used for heating or any of the extra supply which burned the meter out. The cost of replacing the meter would be £3 10s.

Defendants pleaded guilty to fraudulently and feloniously consuming the current, and on this count the stipendiary magistrate (Sir Thomas Lewis) fined them £50 each, or three months' imprisonment, and ordered the withdrawal of the other charges.

Marconi's Wireless Telegraph Company v. Hamilton.

On Tuesday the Court of Appeal dismissed the appeal of Mr. Hamilton against a refusal of Mr. Justice P. O. Lawrence to relieve him from an undertaking given by him in a former action. On May 3, 1920, Mr. Hamilton entered into an agreement with the Marconi Company and Mr. Godfrey Isaacs for compromising certain litigation. The agreement contained a clause by which he covenanted not to disclose the contents of the pleadings. On June 6, 1920, the Company and Mr. Isaacs commenced proceedings against Mr. Hamilton to enforce by injunction the covenant so entered into. The action was tried on October 20 without Mr. Hamilton pleading that the covenant restrained him in the exercise of his business or was contrary to public policy, and an order was made substantially in accordance with the relief asked for. Mr. Hamilton subsequently started an action to have the agreement set aside, alleging that it was obtained by certain misrepresentations by the Marconi Company and Mr. Isaacs; and that it was in undue restraint of his trade and against public policy. The Lord Chief Justice stayed these proceedings, but Mr. Hamilton was given an opportunity of taking proceedings in Chancery for the relief asked. Before taking those proceedings he moved Mr. Justice P. O. Lawrence in the original action to be relieved from the undertaking for the reasons stated. The Judge refused to make the order asked for, and Mr. Hamilton now appealed. The Master of the Rolls, in dismissing the appeal, said it would be unheard of to allow such an appeal where the contention was that the clause complained of was only on the borderline of public policy.

German Wireless Inventor in Trouble.

A German, named William Brandes, was charged at Sunderland on Saturday with having unlawfully broken the conditions of landing in the United Kingdom, and was remanded for a week in custody.

The police statement was to the effect that Brandes was the inventor of wireless apparatus for ascertaining the movements and distances of ships at sea, and for some time he had been in correspondence with persons in London, from whom he wanted £15 000 for the invention. He had come over on a schooner by working his passage, and got permission at Hartlepool to go to London on business. From correspondence found on him, his price of £15 000 was under consideration. He had gone back to Hartlepool too late to board the schooner for Germany. In the hope that a German vessel would be at Sunderland he had gone there, but, being unable to find one, he went to the police station and gave himself up. The man's invention was said to be a clever one, and it had impressed the persons to whom it had been submitted.

Gosforth All-Electric House.

An all-Electric Exhibition House has been open to the public in Gosforth since the 8th inst. The house is a semi-detached villa, and is one of fourteen villas which are being erected on the outskirts of Gosforth, one of the residential areas of Newcastle. The Newcastle-upon-Tyne Electric Supply Company had to extend their mains a short distance in order to give supply to these houses, but all the builders concerned agreed to wire the houses, and also put in one electric heating circuit before offering them for sale.

Following their usual practice, the Supply Company obtained the co-operation of a local furnishing firm and a firm of electrical contractors, and have given the house the title of The Home Ideal. The whole of the electrical installation has been carried out by Robson & Coleman, of Newcastle, who have wired all the houses for the builders, and supplied all the small electrical apparatus. The Supply Company have put in the large apparatus, such as electric cooker, electric clothes washer, dish washer, hot-water circulator, wash boiler, &c., and are giving daily demonstrations of electric cooking, vacuum cleaning, &c.

A luncheon was given at a private inspection for the exhibitors and press, the entire cooking for eight people being carried out on a Jackson No. 21 electric cooker.

New Method of Packing Rubber Wires.

From the beginning of the electric cable industry coils of vulcanised indiarubber wire have been wrapped for delivery in strips of hessian wound spirally around the coils. This method of wrapping has become, from long use, almost a part of the business of electric cable manufacture, and it, therefore, would seem to require a bold man to make a change. However, for some months now W. T. Henley's Telegraph Works Company have been experimenting with the packing of coils of V.I.R. wire in cartons and containers of strong fibre-board, and they now announce that all qualities in sizes 1/0·044 in. (0·015 sq. in.) and 3/0·029 in. (0·002 sq. in.) will be delivered in this improved manner in future. It will be extended to other sizes subsequently, and as soon as arrangements can be made.

The New Method of Packing.

To such an extent had the wrapping of coils in hessian become a custom of the trade that its disadvantages seem to have been generally overlooked. It undoubtedly costs the contractor a considerable sum per annum in wireman's time spent in slowly unwrapping the coils, and it also produces litter which must involve further cost in clearing up. Once a coil is unwrapped it is extremely unlikely ever to be wrapped up again, and so parts of coils left unused may suffer damage. In any case they would deteriorate in appearance and probably in value.

With cartons, the coils are very quickly unwrapped, the litter is infinitesimal and the carton can be used again for keeping portions of unused coils.

The company inform us that the cost to them of this new method of packing is higher than packing by hessian, but they are convinced that it will be such a great advantage and convenience to their customers that they are going on with it. Each coil is packed in a separate carton, and these in turn are packed in containers holding respectively three, four or five cartons.

The containers comply with the railway companies' conditions, and they can be sent by rail anywhere without further protection. Both cartons and containers are clearly marked with their contents, so the taking of stock at any time will be easy.

We show an illustration of the cartons and containers, and are informed that the same method has been adopted for packing "Henley" tape. In this case the cartons each contain 7 lb. of tape, and four of them go in a container.

Hackney Electrical Exhibition.

An interesting exhibition of electrical appliances for household use, organised by the Borough Council's Electricity Department, was opened at the Baths, Lower Clapton-road, on Monday, and will remain open until to-morrow (Saturday). A charge of 6d. is made for admission, which prevents overcrowding, but does not deter interested people from attending.

The Mayor (Councillor W. J. Parker), in performing the opening ceremony, referred in terms of admiration to the excellent progress made by the Council's electricity undertaking and the progressive policy carried out under the direction of the borough electrical engineer, Mr. L. L. Robinson. The department's charges for energy were now the lowest in the country.

The department's new tariff offers several alternative methods of charging, and one which is being especially pushed at present is the following: "In consideration of the premises being wired throughout for electric light, and a fixed charge of 2s. per quarter being paid for each 60 W lamp or equivalent installed, any quantity of electrical energy used per quarter will be supplied at 1d. per unit."

An announcement has been issued that the first twenty cookers ordered from the department will be supplied on trial for three months without any financial liability upon the consumer except to pay for the electricity used. Orders for ten cookers under this system were taken on the opening day of the exhibition.

Lectures have been given during the week by Mr. S. M. Hills and Mr. J. W. Beauchamp.

Some Particulars of the Exhibits.

Demonstrations of electric cooking are given at the stands of the British Electric Transformer Company and the Jackson Electric Stove Company. The former company shows, in addition to "Tricity" cookers, a variety of hot plates, radiators, irons, kettles, &c., while the latter exhibits electric fires and radiators, suction cleaners and other appliances. Other exhibitors are the Sun Electrical Company, who show the "Sunshine" electric cleaner, the "A.B.C." super-electric washer and wringer, table and hanging lamps with silk shades, and illuminated signs; Geo. Nobbs, Ltd., electric cookers, the "Genii" distilling apparatus, and electric coil boiler (which boils a quart of water in ten to fifteen minutes), an electric foot warmer, and the "Rayvac" electric cleaner; the Falkirk Iron Company, "Falco" cookers and double-ray table heaters and toasters, boilers, radiators, kettles and irons; the Carron Company, 2 kW electric fires, which, we are informed, were sold at the rate of 300 a day last autumn, a 6 in. boiling plate, sold at 20s. complete with flex and adapter, a 6 in. boiling ring, which consumes three-quarters of a unit per hour, and also larger rings and a hot-water circulator system; the Wholesale Fittings Company, a fine collection of hanging lamps with alabaster and opal bowls and silk and glass bead shades, flambeaux lamps supported by bronze figures on pedestals, the "Alto" ventilated enamelled steel shades, and the "Reflecto" semi-indirect light fitting with opaline bowl and white enamelled reflector; the British Thomson-Houston Company, sign lighting by floodlights, spotlight projectors with revolving and slide colour screens, a comparison of the "Trutint" artificial daylight unit, for colour matching, with ordinary carbon, gasfilled and vacuum lamps, pedestal and table lamps, and opal and alabaster bowls for semi-indirect lighting; the Hart Accumulator Company, batteries for motor-car starting and lighting, wireless, telephone and other purposes, and portable hand-lamps, with a 4 V accumulator giving 45 hours' light on one charge; Hotpoint Electric Appliance Company, cookers, washing and sewing machines, suction cleaners, radiators, &c.; Metropolitan-Vickers Electrical Company, electroliers and wall sconces with shaded candle lamps, pedestal and table lamps with silk shades, cookers, hot plates, &c.; Belling & Company, electric fires, cookers, hot plates, irons, "M.K." wall plugs and sockets, switch plugs and connectors; Holophane, Ltd., the "Holophane" daylight colour-matching unit contrasted with a light from a bare bulb, and a demonstration of "Holophane" light control, which has the effect of securing a better distribution of light on a given surface than that obtained with bare lamps, and a variety of bowls and shades; Frank Feesey & Company, the "Cascade" electric washer and "Cascado" electric ironer. The ironer is made with 44 in. and 50 in. rolls. Although the stands are confined to manufacturers, Messrs. Linzell Dickinson, & Company, of 7, Cazenove-road, Stoke Newington, are in attendance to hold consultations with visitors requiring the services or advice of contractors.

The Orwell Electric Truck.

A noticeable feature of the exhibition is Ransomes, Sims, & Jefferies' "Orwell" electric truck, which carries two tons at five miles an hour on the level, and is driven by chloride batteries of 129 Ah capacity. A special advantage of these trucks is the small radius in which they can turn.

Mr. Robinson states that these trucks have been found so useful for refuse collection that Hackney Council is buying a fleet of thirty.

There is a good assortment of literature on electricity for the household available at the exhibition, and there is on view a letter from Sir John Snell (the Chief Electricity Commissioner) praising the progressive policy of the Hackney undertaking, and referring specially to the pamphlet on "An Electric House" issued by the department, and consisting of a letter from a Hackney consumer which appeared originally in the "Electrical Times." This sets out the benefits the consumer has obtained by choosing the telephone system of charging, the saving secured on the butcher's bill by means of electric cooking, the reduction of coal consumption from eight tons a year to two tons, &c.

I.M.E.A. Yorkshire Centre: Annual Meeting.

The annual meeting of the Yorkshire centre of the I.M.E.A. was held in the Town Hall, Bradford, on Wednesday, April 5. Representatives were present from Barnsley, Batley, Bradford, Dewsbury, Doncaster, Halifax, Holmfirth, Hull, Leeds, Shipley, Spenborough, Wakefield, and apologies for absence were received from Bridlington, Grimsby, Harrogate, Huddersfield, Lincoln, Mexborough, Rotherham, and Sheffield. Mr. C. N. Hefford (Leeds), Vice-Chairman of the Centre, took the chair, in the absence of Mr. S. E. Fedden (Sheffield), the Chairman of the Centre, who was unable to attend owing to the death of a near relative. Councillor Longley, the Deputy Chairman of the Bradford Electricity Committee, apologised for the absence, owing to indisposition, of Alderman Turner, the Chairman of the Committee. He welcomed the Centre to Bradford, and extended to those present a hearty invitation to inspect the Bradford works during the course of the afternoon. The Chairman of the meeting suitably replied. The report of the Centre Committee for the year ended March 31, 1920, was taken as read, and adopted, and the election of the committee for the ensuing year resulted in a member of the Electricity Committee and the engineer of each of the following undertakings being elected:—Large towns: Bradford, Hull, and Leeds; medium-size towns: Barnsley, Halifax, and Wakefield; small towns: Batley, Harrogate, and Spenborough. The election of officers for the ensuing year was left in the hands of the newly-appointed committee.

At the termination of the annual meeting, a meeting of the newly-appointed Centre Committee was held, at which the following officers were elected for the ensuing year: Chairman of Centre: Mr. W. M. Rogerson (Halifax); Vice-Chairman of Centre, Mr. E. A. Parker (Barnsley); Hon. Secretary and Treasurer, Mr. S. Derwin Jones (Batley). Mr. W. M. Rogerson was re-elected to represent the Yorkshire Centre on the Council of the Incorporated Municipal Electrical Association.

Annual Meeting of the E.T.B.I.

The annual meeting of the Electrical Trades Benevolent Institution was held on Monday at the Institution of Electrical Engineers.

Mr. Highfield, President of the Institution of Electrical Engineers, who presided, said that it was a great pleasure to preside over the meeting, because he appreciated the way in which this Fund, and the Benevolent Fund of the Institution of Electrical Engineers, were acting hand-in-hand. The two funds were clearly desirable, and by working harmoniously together were able to assist, not only those who were members of the I.E.E., but also the large number of employees of the staffs of members of that Institution, and of the staffs of manufacturing concerns, who were not qualified to be members of the I.E.E.

In moving the adoption of the report of the committee and the accounts, Mr. Highfield pointed out the gratifying increase in membership of nearly 100. The sum of £3707 had been invested in the course of the year, bringing the total investments at cost to £18 063. Although every person who was qualified for assistance had been helped, the number of those helped and the amount given in grants was still small, but, none the less, it was more than double that paid out in the previous year, and the largest amount paid out since 1915.

The retiring members of the committee were all re-elected. Price, Waterhouse & Company were reappointed hon. auditors, and a hearty vote of thanks was passed to the Electrical Press for the valuable assistance they had given to the Institution. Votes of thanks were also passed to the honorary solicitors, the Institution of Electrical Engineers, and the hon. secretary, and the meeting concluded with a vote of thanks to Mr. Highfield for presiding over it.

Electric v. Petrol Vehicles.

Mr. F. Ayton points out, with reference to the recent reports in the daily Press on the discussion which followed Mr. R. J. Mitchell's address on Electric Vehicles before the Western Centre of the I.E.E. at Swansea on the 3rd inst., that his remarks have been wrongly reported in some instances. He believes that the advantages of the electric vehicle, in the way of economy, reliability, &c., are such that, whatever may be the price of petrol, it is bound to be increasingly adopted in the sphere of town delivery and transport work. In the discussion he put forward these views, and referred to recent statements in technical journals in the U.S.A., foreshadowing the likelihood of supplies of petrol falling short of the rapidly growing demand, and the probable concomitant increase in the price of that commodity. He pointed out that, where petrol vehicles were at present used for short-distance work in towns and cities, they could with advantage be replaced by electric vehicles.

Silver Medal for Electric Cooker.

On Wednesday, April 19, at the Princes Restaurant, London, the Countess of Carnworth presented the awards made at the recent Cookery and Food Exhibition. Among the recipients were the Falkirk Iron Company, who received a Silver Medal for their domestic electric cooker, this being the highest possible award in the Commercial Class. This firm have also received an order for electric hot cupboards for the liner "The Empress of Scotland," which is being refitted at Portsmouth. Although these hot cupboards had several alterations to their standard pattern, they were made and despatched in five days from the receipt of the order.

Electricity Supply.

Menai Bridge Urban Council have decided to purchase the local electricity undertaking on the terms offered by the company—namely, £700.

Notice is to be given Hove Corporation that, owing to other developments in the district, the Brighton Corporation's arrangement for the supply of electricity in the Aldrington area (which has been a separate service in bulk for some years) is to be discontinued.

The Minister of Transport proposes to confirm the Special Order granted to Lord Weston, Sir George Young, Mr. R. N. Caught, and Mr. H. E. Cooper, and authorising the supply of electricity in Cookham, Berks. Any objections must be sent to the Ministry of Transport by May 13.

Redditch Urban Council is inviting tenders for loans amounting to £92 670. The money is required for various purposes, but mainly for the electricity undertaking. The loans have been sanctioned by the Electricity Commissioners and the Ministry of Health, and are available for trustee funds.

Mr. C. G. Morley New, Cardiff city electrical engineer, reported to the Electricity Committee last Friday that for the year ending March 31 last the units generated showed an increase of approximately two millions, that there were 997 additional consumers connected, and that the total increase in connections was 4 350 kW, including 202 motors of 2 026 h.p. The maximum load on the system shows an increase of 858 kW.

Col. T. C. Ekin will hold an inquiry at Blackpool, on May 2, into the application of the Corporation for sanction to borrow £220 000 for plant and extensions in connection with the Electricity Department. The inquiry will have additional interest in view of the proposals of Preston and Blackburn Corporations for a joint electricity scheme for the whole of Mid-Lancashire, stretching from Blackpool to Bacup. Blackpool regards the scheme as too unwieldy. The scheme provides for the retention of the Blackpool station for peak load purposes only.

The National Industrial Council for the Electricity Supply Industry considered last Friday the dispute, mentioned in our last issue, which has arisen over the refusal of a jointer employed by the Chelmsford electricity undertaking to connect a house to the supply mains on the ground that the wiring had been installed by a man who was not a trade unionist. We understand that there is a reason to hope that some mutually satisfactory solution will be reached before the next meeting of the National Council in the latter part of May.

Fochabers power-house had a narrow escape last week. A heavy rain fell in the district, and the Fochabers burn became flooded. Breaking its left bank at the lowest fall in sight of the Spey, the swollen stream, curving to the left, threatened the electric power-house, which stands at its junction with the Spey. By the time assistance could be summoned the burn had scooped out its bed till within about 3 ft. of the power-house to a depth of fully 3 ft. Fortunately, the flooded stream began to abate as the workmen arrived on the scene, and a hastily-constructed bulwark staved off any immediate danger.

New Schemes and Mains Extensions.

Dundalk Urban Council have applied to the Minister of Economics for sanction to a scheme for extending the municipal electricity works at a cost of £18 500.

Lynn Electricity Committee have decided to apply for sanction to a loan of £10 000 for various alterations and additions in connection with the electricity works.

Porthcawl Council has decided to appoint a sub-committee to examine a scheme for supplying the town with electricity. The total cost is estimated at £10 000.

Stroud Rural Council have decided to offer no opposition to an electricity scheme for the district proposed to be carried out by the Norchard Electric Power Company.

Guildford Corporation has been authorised to borrow £20 000 for a scheme of extensions of the generating plant and mains prepared by Mr. G. W. Spencer Hawes, consulting engineer.

Accrington Council passed a resolution last week authorising application for powers to borrow money in order that the service of electricity may be extended to Oswaldtwistle and other districts.

The secretary of the Walmer Gas Company has informed the Urban Council that the company have decided not to carry out the proposed electric light scheme, owing to the altered circumstances since the War.

Weston-super-Mare Urban Council has granted permission to the Electric Supply Company to erect an overhead line from their station to the Great Western Railway Company's premises for the supply of electricity for power.

Barry Chamber of Trade on Monday considered a report from Sir Charles Bright & Partners regarding the proposed electricity scheme, in which it was suggested that the mains should be laid in the principal thoroughfares. The estimated cost of the scheme is put at £40 000. The Chamber have decided to call a special meeting to deal with the matter, and their observations will then be put before the Council.

Llandudno Council have granted the use of the Town Hall to the Electricity Commissioners on or about May 25 next for a further inquiry required by section 5 (4) of the Electricity Supply Act, 1919, in regard to the supply of electricity in bulk for the North Wales and Chester district. The Commissioners held an inquiry at Llandudno in May, 1921, into the scheme submitted by the North Wales Power Company and the Chester Corporation, and later made an order in favour of the former company.

Following up an interview with the Electricity Commissioners, the directors of the Cannock Chase Colliery Company have decided to proceed with their scheme for the provision of a supply of electricity for Chasetown, Chase-terrace, Burntwood, and Hammerwich. The current will be carried from the Colliery Company's power station at Chase-terrace by means of overhead cables, and the voltage will be 440 for power purposes and 240 for lighting. A sub-station will be erected at Watling-street, and if Brownhills Urban Council require a supply there will be another sub-station at Brownhills. It is proposed to charge a maximum of 8d. per unit for lighting, and for public lighting £3 per lamp per year for Brownhills West, and £3 5s. for the remainder of the Brownhills area. The Colliery Company has intimated to Brownhills Council that if that authority adopt electricity for street lighting, and 100 private consumers can also be secured, the company will supply the necessary current.

Electric Traction.

The manager of the West Ham tramways, in an analysis of the result of cheap midday fares, points out that the increased number of twopenny riders has not even equalled the falling off in the threepenny and higher fares. He says, however, that, having regard to the present financial position of the undertaking and the uncertainty of the future, he cannot recommend any alteration in the fares at present.

After a strike of over three months a settlement has been reached between the employers and employees of the Sunderland and District Tramways Company, and the car service has been resumed. At the suggestion of Mr. Robert Richardson, M.P. for Houghton-le-Spring, both sides agreed to a conference, and at this meeting the employees agreed to accept a reduction of 5s. per week in wages. Eleven weeks ago the men were asked to accept reductions up to 10s. a week over and above the national reduction of 3s. a week.

Mr. R. L. Horsfield, manager of the Cardiff Corporation Tramways, submitted a report to the Tramways Committee on Friday which showed that the passenger receipts for the year ended March 31 amounted to £277 855, a decrease of £13 054 compared with last year. Total car mileage was 2 894 286 miles, a reduction of 92 592 miles, and the number of passengers carried 37 589 443, against 40 114 675. Mr. Horsfield attributed the decrease of receipts to the depression in trade and the interference with traffic by the reconstruction of the tramway track. The wages bill for the year shows a decrease of £5 651.

In a paper read before the Institute of Transport last week, Mr. J. K. Bruce, traffic manager of the L.C.C. Tramways, stated that cars fitted with a new type of motor were capable of an increase in speed of 10 per cent. If this increased speed were maintained throughout the service of, say, fifteen hundred cars, it would mean a saving of approximately 170 cars, and this would effect a saving, in repairs alone, of £70 000 a year. If one second were saved at every stop made by the cars the total daily saving would be 220 hours, which would enable about 2 000 additional miles to be run each day without increase in the number of cars.

Manchester Tramways Committee have decided to contribute £50 000 towards the relief of the rates. Last year the undertaking was expected to make what was then an annual contribution in relief of rates, and the sum required of it was £115 000. The undertaking was not then in a position to make such a payment, but since then it has been decided not to make demands on the trading departments for rate relief. The £50 000 now voted seems to be a breach of this understanding. The approximate expenditure for the year ended March 31 last was £1 994 551, or £43 449 less than the estimate. The estimated revenue for the new year is £1 894 495—a reduction on last year, in view of the probable loss on the new fares, of, roughly, £100 000.

The draft financial statement of the Leeds City tramways for the year ended March 21 last was presented at a meeting of the Tramways Committee on Monday. The income for the year was £959 702, or an average of 24·695d. per car-mile, compared with £995 638, or 23·480d. the previous year, the decrease, therefore, being £35 935. The total working expenses were £702 250, an average of 18·070d. per car-mile, the corresponding expense for the previous year being £729 345 and 17·2d., a decrease of £27 095. The gross profit left to be carried forward was £257 453, a decrease of £8 840. The war charges, income-tax, rent of lines, permanent way renewals, &c., exceeded the gross profit carried forward by £43 266. This deficit is accounted for by the fact that during the year £140 561 has been expended on permanent way renewals and £63 556 on permanent way repairs, a total of £204 000, compared with £155 000 in 1920. The amount in the reserve fund on March 31 was £56 818. £36 818 being to general reserve and £20 000 in respect of third-party risks. Wage reductions of all classes of employees amounted to £23 000 approximately. The Committee adopted the statement. A year ago it was estimated that there would be a loss of over £100 000, whereas it has proved to be £43 266. This is the first time in the history of the undertaking, which dates back to 1897, that there has been a deficit, and, on the other hand, the total contributed by the tramways department by March 31, 1921, to the relief of rates was £1 514 492.

Personal and Appointments.

Mr. W. J. Smither has been appointed electrical engineer to the Dorchester Town Council.

Faversham Town Council has reduced the salary of the electrical engineer (Mr. G. Somerville) from £450 a year to £416.

Mr. J. C. Austen, managing director of Austen & Barnes, Ltd., electricians, has been elected chairman of the Tonbridge Urban Council.

Mr. Frank B. Jewett, of New York, has been nominated president of the American Institute of Electrical Engineers for 1922-3.

Mr. P. Robson, of Clayton & Shuttleworth, has been appointed by the Federation of British Industries to go to the Genoa Conference in the capacity of expert on agricultural machinery.

Mr. J. A. Bromley, manager of the Keighley Corporation Tramways, has been appointed tramways manager at York at £600 a year in succession to Mr. J. W. Hame. Mr. Bromley went to Keighley from Leeds, where he was chief assistant rolling stock superintendent, about eighteen months ago.

In recognition of his many and long services for the benefit of Sheffield, the Freedom of the City was conferred on Sir William Clegg last Friday, the anniversary of his seventieth birthday. Among the many positions held by Sir William is that of chairman of the Tramways Committee since the introduction of electric traction.

Mr. H. C. Tofield has resigned his position as managing director of Tofield & Robinson, Ltd., electrical engineers, of 165, Edmund-street, Birmingham, and has commenced business on his own account at Temple-passage, Temple-street, Birmingham, to which address all correspondence should be sent. He has been appointed sole agent for "Delco" electric lighting and pumping plants for the county of Warwickshire, and will be exhibiting these at the Birmingham and Midlands Industrial and Commercial Efficiency Exhibition to be held at Bingley Hall from May 25 to June 3 next.

Major Henry Mattinson, chief civil engineer to Manchester Tramways Department, has been appointed general manager in succession to Mr. J. M. McElroy, who has resigned owing to ill-health. Major Mattinson's salary will be £1 400 a year, and he will begin his new duties on July 1. Manchester tramways system covers 220 miles of single track in the city and surrounding districts, and Major Mattinson has been responsible for the construction of practically all of it. He accompanied Mr. McElroy on his visit to America and the Continent to study traffic conditions, and collaborated with him in reports on tramway traffic congestion. During the war, as construction engineer of light railways, he built over 100 miles of light railway from Gaza to Aleppo, and after the Turks were defeated in 1918 he took over the restoration of the 600 miles of captured railway from Haifa to Damascus, Beirut and Aleppo.

Business Items, &c.

Horace Green & Company have opened offices at Amberley House, Norfolk-street, London, to deal with home and export business in London.

Mr. C. G. Dunster announces that in future he will carry on alone the business of Dunster & Bacon, electrical engineers, of 19, North Holmes-street, Canterbury.

Important orders recently received by the Underfeed Stoker Company include travelling grate stokers for Eastbourne, St. Marylebone, Wolverhampton, Stafford, Liége, and Cossipore (India) electricity undertakings.

In reference to the No. 10 model 50-ton tyre press recently introduced for small garages and overseas depots, by Hollings & Guest, which is listed at £120, the makers now state that they are prepared to quote a special discount on this model. Also, each of these presses will be tested up to 80 tons pressure before leaving the works.

In addition to manufacturing all classes of electrical machinery and cables, the A.C.E.C. (Ateliers de Constructions Electriques de Charleroi) specialise in the production of moulded insulating materials for switch handles and bases, brush spindles, terminal covers and bases, arc shields, &c., and have recently built a new factory for the mass production of these parts.

From Monday next, May 1, the London offices and stores of J. H. Tucker & Company will be removed from 217, Shaftesbury-avenue, to 101, Dean-street, W. 1, close to Frascati's Restaurant and three doors only from Oxford-street. The telephone number remains the same as hitherto, namely, 3215 Gerrard. In addition to greatly increased stock accommodation, the new premises will also provide showrooms, in which a representative display of "Tucker" accessories, ironclad gear and switchgear will be permanently displayed, as well as a series of practical demonstrations by the many different controls available by the use of different types of "Tucker" switches. The trade are cordially invited to visit the firm at their new address.

Mr. J. W. Beauchamp read a paper on Monday before the Liverpool Sub-Centre of the Institution of Electrical Engineers entitled, "Engineering Advertising and the Work of the E.D.A." The paper was well illustrated by lantern-slides showing various forms of advertising. Among those who took part in the discussion which followed were Messrs. Dickinson, Clothier, Hansom, Collie, Holttum, Collin, and Nisbett.

Wireless and Telephone Notes.

The extension of the Bergen wireless service, for which the Storting has voted 100 000 kroner [about £4 000], is expected to be completed in June. The radius of the wireless telephone will enable it just to reach the North of England.

The Grimsby telephone exchange, which was the first complete automatic installation in the country, is to be equipped this month with an extension providing 550 additional lines. A new underground cable between Grimsby and Hull is being laid.

It is reported from Moscow that the Council of People's Commissaries have granted a concession for telegraphic communication between India and Europe. Communication will be through Russian territory, and there will be connection with Turkey, Egypt, Persia, and the Mediterranean countries.

Owing to numerous requests from amateur users of wireless receiving sets, the two daily weather messages sent out from the Air Ministry are now being distributed at a slightly lower rate than previously. Investigation of the requests showed that a number of amateur wireless users situated in remote rural localities are carefully picking up the Air Ministry weather forecasts, and are handing them on at once to neighbouring farmers.

It is stated that the Marconi Company has proposed to the Mexican Government a scheme whereby the company would control for fifty years all wireless stations built or to be built on Mexican territory. After the expiration of the fifty years the wireless stations would be turned over to the Government or the concession renewed. The Government regards the offer in its present form as unacceptable, but it is believed would be prepared to give it favourable consideration if modified.

A wireless-telephonic service, claimed to be the longest line of its kind in the world open to public use, was opened between Peking and Tientsin on March 7. The equipment was supplied by the China Electric Company and was manufactured exclusively by the International Western Electric Company (Inc.), New York. The system as perfected in the Peking-Tientsin service ensures transmission when connected with telephone central offices. The tests that were applied at the opening ceremony were entirely successful. The distance between Peking and Tientsin is 80 miles.

The "Cornell Special," an express train which runs between New York and Ithaca, has just been fitted with a complete radio-telephone installation capable of receiving and transmitting messages over a considerable distance. In the buffet car there is a loud-speaking telephone, and receiving sets are affixed to the chair of each passenger. Referring to experiments made before the present apparatus was fixed, the "Radio Globe" says it was found that while the train was moving through cuttings and over bridges the signals frequently ceased entirely, while they were invariably weaker than when on the ordinary open track. This defect has not been entirely overcome, but is being corrected. In tunnels the apparatus worked excellently, but again, when in the train sheds in Hoboken all signals stopped, due to the great quantity of steel used in the construction of the buildings.

Institution Notes.

The annual convention of the Canadian Electrical Association will be held in Ottawa from June 15 to 17 inclusive.

The 69th anniversary festival of the London Association of Foremen Engineers will be held at Cannon-street Hotel, London, on Saturday, May 6, at 6 p.m. Mr. F. W. Bellamy will take the chair.

The Association of Engineers-in-Charge will hold an informal meeting on Saturday, May 6 (7.30 p.m.), at St. Bride's Institute, Bride-lane, Fleet-street, E.C. 4, to discuss "Uniflow v. Multiple Expansion Steam Engines." Visitors are invited to be present and take part.

The Sessional Examinations of the Institute of Cost and Works Accountants will take place on June 19, 20, and 21, and will be held in London, Manchester, Birmingham, Sheffield, Glasgow, and Bristol. Application should be made on Form "C," obtainable from the Secretary, 38, Grosvenor-gardens, at least twenty-one days before the date of examination.

At the Congress of the Institute of Transport, which will be held in London from the 17th to the 20th prox., all branches of transport will be represented. Delegates will attend from the British Dominions, the United States and the Continent. On the mornings of the first three days papers will be read and discussed at the Institution of Civil Engineers, Great George-street, and the afternoons as well as the Saturday following will be devoted to visiting places of special interest. The third dinner of the Institute will be held on May 18.

Members of the West of Scotland Branch of the Association of Mining Electrical Engineers last Saturday afternoon visited the Clydesmill Power Station, Cambuslang, of the Clyde Valley Electrical Power Company. They were shown over the station, and the plant and general arrangements were fully explained by the resident engineer and other officials of the company. The following officers have been elected for the next session of the Branch:—President, Mr. D. Martin, Glasgow; vice-presidents, Messrs. D. M'Queen and D. L. Frew; treasurers, Messrs. C. L. Brown and Melville, C.A., Glasgow; secretary, Mr. D. S. Baddeley, 50, Wellington-street, Glasgow.

Obituary.

The death took place on April 2 of Mr. WALTER JOSEPH BRINN, of Old Charlton (late of the Western Brazilian Telegraph Company), aged 70.

We regret to record the death of Mr. JAMES BIRD GARNHAM, head of the firm of J. B. Garnham & Sons, metal merchants. Mr. Garnham was eighty years of age.

We regret to record the death, at the age of thirty-five, of Mr. HAROLD EMMOTT, the only son of Mr. Walter Emmott, consulting engineer of Halifax, who died suddenly in his father's office last Thursday. Mr. Harold Emmott was educated at the Higher Grade School and Technical College, Halifax, and at Woodhouse Grove School, Aperley Bridge. He was apprenticed with Mr. Shaw, City Electrical Engineer, Worcester, and afterwards acted as assistant to Mr. Busby, of the British Insulated & Helsby Cables, Ltd., on London cable contracts, and with the L.C.C. Electricity Department. He joined his father in March, 1913, his first work being the installation of electricity supply to the town of Bingley. He was a member of the 6th London Field Ambulance (T), transferring to the 2nd Northern General Hospital, Leeds, and on the outbreak of war he was mobilised, promoted sergeant, and was in charge of the X-Ray Department at Beckett's Park, Leeds, until the end of 1915. He then applied for and obtained a commission in the R.E., and served in France until March 23, 1917, when he was invalided home. He then obtained a position as constructional engineer with the Bradford Corporation, rejoining his father some two years ago. Mr. Emmott was an Associate Member of the Institution of Electrical Engineers, being admitted a student in 1903.

The death took place on Sunday, at the Red Cross Hospital for officers at Brighton, from tuberculosis contracted on service in the Near East, of CAPT. L. C. CARUS-WILSON, M.C., R.C.S., assistant experimental officer at the S.E.E., Woolwich, Associate of the Institute of Radio-Engineers of America. Capt. Carus-Wilson, who was only 25 years of age, was the second son of Prof. Ashley Carus-Wilson, late Prof. of Electrical Engineering at McGill University, Montreal. In February, 1914, he passed into Woolwich second on the list as a prize cadet, receiving his commission in the Royal Engineers in November, 1914. He served continuously throughout the war in France, Belgium, and Italy, and received the M.C. "for invaluable services rendered at the Battle of Messines, where, under heavy shell fire during seven days, he showed the greatest skill and resource" in using, for the first time in action, the latest invention in wireless signals. Through the summer of 1918 he commanded the Signal Company of the 9th (Scottish) Division, which led the victorious march to the Rhine. After lecturing on electricity to the British troops at Ohligs, he was recalled, and appointed by the War Office in 1919 to be the representative British officer at l'Ecole Supérieure d'Electricité of Paris. There he won the diploma in radio-telegraphy, &c., of the University of Paris, and passed out of the wireless school first on the long list of foreign officers who completed the course. He was then attached to the Wireless Headquarters Staff at the Horse Guards, and later on, when engaged in original research at Woolwich, was appointed to represent the War Office during the installation at Cairo of the first link of the Imperial Wireless Chain.

Opening of Anglo-Egyptian Wireless Service.

The ANGLO-EGYPTIAN WIRELESS SERVICE *viâ* the Imperial wireless stations at Leafield and Cairo commenced on Monday. Telegrams are accepted at any post-office for Egypt, Palestine, and Syria for transmission, and a corresponding service is available in the opposite direction. The rates of charge are 3d. a word less than the corresponding cable rates for full-rate traffic, and 1½d. a word less than the corresponding cable rates for deferred traffic. Press messages may be sent to and from Egypt (first region) and Palestine at 2½d. and 3½d. a word respectively. Telegrams intended for transmission by this route should be marked "*viâ* wireless." In addition, arrangements have been made, pending the provision of further stations of the Imperial wireless chain, for telegrams addressed to places beyond Egypt, served by the system of the Eastern Telegraph Company, to be forwarded by wireless to Cairo and thence by the company's service to their destination at the normal through rates of charge.

Miscellaneous.

In view of the need for economy in public expenditure the post of H.M. TRADE COMMISSIONER AT SINGAPORE has been suspended.

The late Mr. ALEXANDER MCGEOGH, of William McGeogh & Company, brass founders and electrical accessories manufacturers, has left estate valued at £37 631.

The Salaries and Wages Committee of EDINBURGH Town Council have decided that all Corporation officials receiving more than £400 a year should be asked to submit to a voluntary reduction of 5 per cent. of their salaries.

MR. WM. OGILVIE, an electrical engineer, was found dead last week in the Rothwell sub-station of the Yorkshire Electric Power Company. At the inquest it was stated that Mr. Ogilvie had suffered from insomnia, and had lately been very much depressed. A verdict was returned that deceased electrocuted himself whilst temporarily of unsound mind through neurasthenia.

Imperial and Foreign Notes.

The WEST MAITLAND (N.S.W.) municipal electrical plant, which cost £15 000, was put into operation on Feb. 22.

BROKEN HILL (N.S.W.) Council, who have their own generating station, have under consideration a proposal to obtain a supply of electricity from a local mining company.

HOBART (Tasmania) and neighbouring municipalities recently discussed a proposal to establish a metropolitan and district water and sewerage board. It was suggested that the engineering works should be designed with the dual purpose of water and electric power supply in view, and a committee has been appointed to deal with the question of funds for the necessary surveys.

The Tasmanian Public Works Committee is inquiring into the proposal to provide the ZEEHAN MINING DISTRICT with ELECTRIC POWER to the extent of 375 kW. The Mount Lyell Company offer to supply the energy required at £6 per H.P.-year, and the transmission line would cost £20 000. The annual capital charges are estimated at £2 500, and the working expenses at £2 000.

The reorganisation of the FRENCH TELEGRAPH AND TELEPHONE SERVICE is provided for in two bills before the Council of Ministers. The accounts of each service will be kept separate, and 1 675 000 francs are to be allocated for telephone line extension and the introduction of automatic telephony.

The fortieth anniversary of the NEW YORK electricity supply service is to be celebrated on September 4 next. The original Edison Company had sixty customers, with 1 200 lamps, connected, but at present there are 296 560 lighting consumers using about 9 million lamps, and, in addition, supply is given to 680 000 H.P. in motors and 12 800 kW for heating.

The Great Western Power Company has completed the installation of two 30 000 H.P. double-hung impulse turbines, operating under a head of 1 008 ft., at the Caribon power-house on the Feather River, CALIFORNIA. Another 30 000 H.P. hydro-electric unit is to be installed in order to complete the first half of the scheme, but ultimately 180 000 H.P. will be developed at the station.

A new steam-driven power station, which will have an ultimate capacity of 240 000 kW, is to be erected in EAST ST. LOUIS (Mo.) by the Union Electric Light & Power Company. The plant will supply the rapidly-increasing demand for electricity in St. Louis and vicinity. The station will be named the Cahokia steam-power plant, and will have an initial capacity of 60 000 kW. The first two units will be of 30 000 kW each, supplied with steam at 300 lb. pressure at the throttle, and will deliver electrical energy at 13 200 V, 50 cycles.

Electric and petrol as well as horse-drawn vehicles are being used by Abraham & Strauss, owners of one of the largest stores in Brooklyn, for transport purposes. Horse vehicles are employed for trips of less than 10 miles, electric trucks for a daily mileage of 10 to 40, and petrol for journeys of 40 to 130 miles. The firm have employed twenty-one electric vehicles for some years, and they report that the ELECTRICS ARE CHEAPER PER UNIT HAULED than any other vehicle, and besides being cheaper, they are much more satisfactory from every point of view. In Chicago 105 electric trucks are now employed for ice-cream deliveries, against one in 19[illegible]. The average mileage is 16 to 30 per day. In every case satisfaction has been given, and one firm reports that the delivery costs were halved by the electric vehicles.

Possible Trade Openings.

An old-established firm of good standing, with suitable connections throughout AUSTRALIA AND NEW ZEALAND, desire to secure the representation of United Kingdom manufacturers of electrical machinery, motors, dynamos, copper cable, &c. The firm have their own offices in Melbourne, Sydney, and Port Adelaide, and agencies in Brisbane and Fremantle. Further particulars can be obtained from the Department of Overseas Trade. (Ref. No. 431.)

The British Consulate at CASABLANCA reports that concessions for electric light and power stations at the towns of Marrakesh, Mazagan, and Saffi, in Morocco, have recently been granted. The station at Marrakesh is apparently to have an initial capacity of 1 200 h.p., the station at Mazagan 750 h.p., and that at Saffi 1 200 h.p., for the generation in each case of three-phase current at 50 cycles, with a consumer's voltage of 115 for lighting and 200 for heating purposes.

H.M. Agent and Consul-General at TANGIERS reports that a concession has also been granted for the supply of electric light and power to the town of Rabat and its surroundings, the supply station to have a capacity of 1 000 kW for the generation of three-phase current at 50 cycles and 55 000 V, which is transformed down to a consumer's voltage of 110 for lighting and 190 for motive-power purposes. Cuttings from the local "Bulletin Officiel," giving details of the concession and the proposed scale of charges, can be consulted by firms interested at the Department of Overseas Trade.

H.M. Consul at Cluj (Transylvania, ROUMANIA) reports that the Municipality of Cluj is trying to arrange for the construction of a pipe-line for the supply of natural gas from the Kissarmas district (60 k.m. distant) for domestic, commercial, and industrial purposes in Cluj (previously known as Klausenburg or Kolozsvar), and that it is possible that the extension of the electric-power station and the introduction of an electric tramway system may be combined with the project. Full particulars are not yet available, but preliminary information may be obtained from the Department of Overseas Trade.

Electrical Imports and Exports.

IMPORTS.—The following are official values of electrical machinery, apparatus and material imported into this country (*a*) during March, 1922, and (*b*) the aggregate figures from Jan. 1 to March 31, with increase or decrease compared with corresponding periods of 1921 :—

Electrical machinery, (*a*) £136 511 (increase £64 658), (*b*) £381 545 (increase £134 629); telegraph and telephone cables, other than submarine, (*a*) £4 818 (increase £2 599), (*b*) £10 915 (decrease £16 824); telegraph and telephone apparatus, (*a*) £13 463 (decrease £20 276), (*b*) £39 287 (decrease £49 145); other electrical wires and cables, rubber insulated, (*a*) £11 188 (increase £9 504), (*b*) £19 361 (increase £11 592); with other insulations, (*a*) £8 269 (decrease £10 801), (*b*) £16 509 (decrease £22 188); carbons, (*a*) £5 157 (increase £512), (*b*) £10 290 (decrease £22 781); glow lamps, (*a*) £11 547 (decrease £9 755), (*b*) £52 710 (decrease £9 964); arc lamps and electric searchlights, (*a*) £50 (decrease £10), (*b*) £50 (decrease £4 741); parts of arc lamps and searchlights (other than carbons), (*a*) £1 031 (decrease £361), (*b*) £2 169 (decrease £2 984); batteries, (*a*) £8 670 (decrease £11 545), (*b*) £15 685 (decrease £34 153); meters and electrical instruments, commercial and scientific, and electricity meters, (*a*) £3 674 (decrease £22 440), (*b*) £14 317 (decrease £53 822); switchboards, (*a*) £414 (increase £414), (*b*) £1 379 (increase £209); other electrical goods and apparatus, (*a*) £47 229 (decrease £47 740), (*b*) £133 990 (decrease £163 824). Total of electrical machinery, apparatus and material (other than uninsulated wire), (*a*) £252 020 (decrease £45 241), (*b*) £698 207 (decrease £233 996).

EXPORTS.—The exports of electrical machinery, apparatus and material (*a*) during March, 1922, and (*b*) from Jan. 1 to March 31, with increase or decrease compared with corresponding periods of 1921 were as follows :—

Electrical machinery, (*a*) £485 115 (increase £67 962), (*b*) £1 436 394 (increase £181 583); including railway and tramway motors, (*a*) £22 554 (increase £13 605) (*b*) £53 610 (decrease £1 545); other generators and motors, (*a*) £277 451 (increase £48 208), (*b*) £799 190 (increase £90 917); and electrical machinery unenumerated, (*a*) £185 110 (increase £6 149), (*b*) £583 594 (increase £92 211); telegraph and telephone cables, submarine, (*a*) £17 773 (decrease £68 909), (*b*) £82 251 (decrease £204 681); other than submarine, (*a*) £29 839 (decrease £101 301), (*b*) £145 736 (decrease £335 037); telegraph and telephone apparatus, (*a*) £180 266 (increase £27 181), (*b*) £541 069 (increase £95 428); other electrical wires and cables, rubber insulated, (*a*) £48 527 (decrease £106 049), (*b*) £145 573 (decrease £348 090); with other insulations, (*a*) £98 510 (decrease £119 718), (*b*) £337 459 (decrease £263 127); carbons, (*a*) £3 502 (decrease £6 030), (*b*) £12 608 (decrease £27 850); glow lamps, (*a*) £38 349 (decrease £11 154), (*b*) £96 942 (decrease £14 201); arc lamps and searchlights, (*a*) £1 753 (increase £1 353), (*b*) £2 845 (increase £15); parts of arc lamps and searchlights other than carbons), (*a*) £611 (increase £544), (*b*) £1 392 (decrease £625); batteries, (*a*) £47 520 (decrease £9 998), (*b*) £105 913 (decrease £111 563); meters and electrical instruments, commercial and scientific, and electricity meters, (*a*) £33 747 (decrease £2 372), (*b*) £105 941 (decrease £10 272); switchboards, (*a*) £15 501 (increase £1 355), (*b*) £125 865 (increase £79 805); other electrical goods and apparatus, (*a*) £113 573 (decrease £121 149), (*b*) £336 849 (decrease £366 776). Total of electrical machinery, apparatus and material, other than uninsulated wire, (*a*) £1 114 586 (decrease £458 285), (*b*) £3 476 837 (decrease £1 352 391).

Tenders Invited and Accepted.

UNITED KINGDOM.

MANCHESTER TRAMWAYS COMMITTEE. May 9.—Trucks for tramcars. Specifications, &c., from the Manager, 55, Piccadilly, Manchester.

PROVIDENCE CONGREGATIONAL CHURCH, MIDDLETON. May 1.—Electric wiring and fitting. Specifications from the Borough Electrical Engineer.

GLASGOW LIGHTING DEPARTMENT. May 1.—Electrical fittings and accessories, lamp pillars, &c. Specification can be obtained at the Lighting Department, 20, Trongate, Glasgow.

PEMBROKE (CO. DUBLIN) Urban Council. May 2.—Two 250 kW rotary converters, with switchgear, cable connections, &c. Specification, &c., can be obtained at the Council offices.

YORK CORPORATION. May 5.—500 kW rotary converter, transformer, switchgear, &c., for Wellington-row sub-station. Specification, &c., from the City Electrical Engineer.

PRESTON ELECTRICITY DEPARTMENT. May 30.—(*a*) two 10 000/12 500 kW turbo-generator sets, complete with condensing plant, auxiliaries, and piping connections; (*b*) house service plant, comprising one 1 200 kW turbo-generator, and two a.c. 6 600/220 V d.c. generators. Particulars from the Town Clerk, Mr. A. Howarth, Town Hall, Preston.

ASIA.

The Acting British Consul at BANGKOK reports that the date for the presentation of tenders for telegraph and telephone material for the Department of Posts and Telegraphs (see THE ELECTRICIAN, April 14, p. 458) has been extended to June 28.

We regret that in our list of "Tenders accepted" last week the name of CHAMBERLAIN & HOOKHAM was incorrectly spelt in two paragraphs.

COMMERCIAL INTELLIGENCE.

County Court Judgments.

[NOTE.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

BRADBEER, Jno. Edward, 2c, England's-lane, N.W., electrical engineer. £10 18s. 10d. Feb. 14.

CLARKE, E. E., & COMPANY, Lancashire-street, Morecambe, electrical engineers. £16 6s. 8d. Feb. 27.

HOLMES & CROWTHER, Palatine-chambers, Halifax, electrical factors. £20 4s. Feb. 22.

HURLINGHAM ELECTRIC COMPANY, 283, New King's-road, S.W., electricians. £13 6s. 6d. Feb. 21.

MACAULEY, Mr. R. A., 48, Ashton New-road, Beswick, electrical engineer. £11 15s. Feb. 23.

SPURBER MANUFACTURING COMPANY, 1A, Luxor-street, Camberwell, electrical engineers. £25 13s. 11d. Feb. 14.

STUBBS, Arthur, 200, Midland-road, Bradford, electrical contractor. £17 6s. 4d. Feb. 22.

Bills of Sale.

[The undermentioned information is from the Official Registry. It includes Bills of Sale registered under the Act of 1822 and under the Act of 1878. Both kinds require registration every five years. Up to the date the information was obtained it was registered as given below; but payment may have been made in some of the cases, although no notice had been entered on the Register.]

JACOBS, Ernest, 2, Sidworth-street, Hackney, electrical engineer. April 21. £35.

DEXTER, Robert Hart, 270, Penistone-road, Sheffield, electrician. April 24. £30.

Deeds of Arrangement.

GRIFFITH, Benjamin, trading as EXCEL ELECTRIC COMPANY 30, South Castle-street, Liverpool, electrician. Filed, April 22. Trustee, T. W. Stanfield, 24, Sir Thomas-street, Liverpool. Secured creditors, £50; liabilities unsecured, £1 708; assets, less secured claims, £550.

ROWE, Walter William, trading as M. ROWE 26 Augusta-street, Birmingham, electro-plater. Trustee, A. Cripwell, 12, Cherry-street, Birmingham. Filed April 19. Liabilities unsecured £628, assets, less secured claims, £200.

WEBSTER, E. W., and WEBSTER, W. G. F., trading at 48-50, Rendezvous-street, and the Harbour, Folkestone, as WEBSTER & SON, automobile and electrical engineers. In this matter (see last week's ELECTRICIAN) the following are creditors :—Sloan Electrical Company, Ltd., London, £397; Clark, Hunt & Company, Ltd., London, £254; Callander's Cable and Construction Company, Ltd., London, £110; General Elec. Company, Ltd., London, £69; Baxter & Caunter, Ltd., London, £67; Vulcan Elec. and Mechanical Company, Ltd., London, £55; Rogasine & Company, London, £51; Harper, Geo. R., & Sons, Birmingham, £51; Edison Swan Elec. Company, Ltd., Ponder's End, £52.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

COUNTY OF LONDON ELECTRIC SUPPLY COMPANY, LTD., London, E.C. Registered April 4, Trust Deed dated March 23, 1922, securing £500 000 debenture stock; general charge, excluding certain lands and premises at Barking, subject to existing Trust Deed securing first and second debenture stock. *£1 000 000. March 29, 1921.

SCIENTIFIC TRADERS, LTD. (late TELEPHONE THIRD HAND, LTD.), London W. Registered April 10, £2 000 debentures, present issue £500; general charge. *Nil. March 30, 1921.

Satisfactions.

NAIROBI ELECTRIC POWER & LIGHTING COMPANY, LTD., London, E.C. Satisfaction registered April 6, £12 000, balance of amounts registered Sept. 29, 1913, and July 30 1915.

SPICER & COMPANY, LTD., London, E.C., electrical engineers. Satisfaction registered April 10, £800, balance of amounts registered Feb. 26, 1915, and March 17, 1922.

SUN ELECTRICAL COMPANY, LTD., London, W.C. Satisfaction registered April 12, £275, part of amount registered April 19, 1911.

Private Meetings.

[Inclusion under this heading does not necessarily imply failure. Many private meetings are called merely for the purpose of the debtor consulting his creditors as to his position when he may not be insolvent.]

THE B.E. COMPANY (OF LONDON AND BIRMINGHAM), LTD. (in voluntary liquidation), wholesale manufacturing electricians, 57, Upper Thames-street, London, E.C., and at Birmingham. A meeting of creditors was held last week at the Cannon-street Hotel, London, when the representative of the General Accessories Company, the principal trade creditors, was elected to the chair. Mr. Frederick Roland, C.A., of 70, Queen Victoria-street, E.C., stated that the usual resolution for voluntary liquidation had been passed, and he had been appointed as the liquidator. He proceeded to read figures from which it appeared that the liabilities totalled £9 959, made up as follows :—Trade creditors, £7 240; cash creditors, £2 294; and unsecured balance due to bank, £425. Assets were estimated to realise £7 400, from which had to be deducted £310 for preferential claims, leaving net assets of £7 090. The assets consisted of cash in hand, £17; stocks, £2 864, estimated to realise £2 500; office furniture and fittings, £1 340, expected to produce £500; book debts, £3 541, valued at £2 500; lease of London premises, £20; and unpaid calls, £1 850. The company had two branches in Birmingham—a sales depot, and an assembling and manufacturing shop. The Birmingham premises were valued in the books at £3 381, but they were charged to the bank to secure £2 425. The premises might not realise sufficient to discharge the bank's claim, and they had been included as unsecured creditors for £425. The company invested £2 000 in a subsidiary company called The B.E. Manufacturing Company, which had a nominal capital of £6 000, and which manufactured articles for the parent company to sell; at the moment no value had been placed upon those shares. The B.E. Company (London and Birmingham), Ltd., was registered as a private company on June 22, 1916, with a nominal capital of £2 000, and it acquired for £1 000 the stock and fixtures of a business previously carried on by Mr. Fauke in London and Birmingham. In January, 1919, the capital was increased to £10,000, and, finally, the whole of the capital was issued, and the company seemed to have received £9 000 for shares. On November 15, 1920, the capital was increased to £20 000, by the creation of 10 000 cumulative preference shares of £1 each, bearing interest at the rate of 8 per cent., free of income tax. A number of those preference shares had also been issued for cash. During the year to June, 1917, the company made a net profit of £308, and a dividend of 10 per cent. was declared. The following year the profit rose to £1 062, and there was a dividend paid of 15 per cent. During the year to June, 1919, the profit dropped to £475, but there was a dividend declared at the rate of 15 per cent. Since the inception of the company the total amount paid in directors' fees was only £21. The period to June, 1920, was the most successful in the history of the company, the net profit being £2 412. That amount, however, was not available for dividend, owing to the liability for E.P.D., which, however, was never paid, owing to the subsequent losses. The troubles of the company began about that time. There was some difficulty in regard to the output, and the factory was purchased in Birmingham. During the year to June, 1921, there was a loss of over £4 000 on the Birmingham factory, and the trading of the company generally for that year showed a loss of £7 000. The present position of the company was due to the loss at Birmingham, and the slump in trade. The company was only a small one, and when it met with misfortune it had no reserves to fall back upon. In answer to a question, the liquidator said he did not think there was any prospect of a reconstruction scheme being brought forward. On the motion of the chairman, a resolution was passed confirming the voluntary liquidation of the company with Mr. Roland as liquidator, and a committee of five of the principal creditors was also appointed.

TUCKER, Spencer John, trading as TUCKER & BATESON, wholesale electrical suppliers, 55, Berners-street, London, W. In response to a circular letter issued by Mr. T. L. Summers, accountant, of 64, Victoria-street, S.W., a meeting of the creditors of the above was held recently at Winchester House, Old Broad-street, E.C. The statement of affairs presented showed liabilities of £1 108, of which £866 was due to the trade and £242 to cash creditors. After allowing for preferential claims, net assets were estimated to realise £133. It was stated that the debtor commenced the business in 1919 with a capital of £40, but he had since borrowed from relatives, who were now creditors to the extent of £377, but one held securities valued at £135. The business had been carried on at a loss, and the present position was due to that fact. A deed of assignment had already been executed owing to pressing creditors. It was stated that if the deed was accepted by the creditors the cash claims would be withdrawn. A resolution was passed confirming the deed already executed. The following are creditors :—Davies, Kent & Stewart, Ltd., London, £70; Kent, William, Burslem, £61; Falk, Stadelmann & Company, London, £25; Johnson & Jorgenson, London, £24; Electric Heating Company, Croydon, £20; Boyton, Charles, & Company, Ltd., London, £16; Marshall Electric Company, London, £14.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Winding-Up Petition.

HUBERT D. CARTER (BANGOR), LTD. A petition for the winding-up of the above-named company has been presented by Higgin, Ltd., Manchester, and is to be heard at the Court House, Bangor, May 8, at 11 a.m.

Companies Winding-up Voluntarily.

ECLIPSE CARBORUNDUM & ELECTRITE COMPANY, LTD. George Lord, Capel House, 62, New Broad-street, London, E.C. 2, appointed liquidator. Meeting of creditors at the liquidator's office on Friday, May 5, at 12 noon.

SOLECTRIC COMPANY, LTD. F. N. Clarke, 4, Pavilion buildings, Brighton, appointed liquidator. Meeting of creditors at liquidator's office on Friday, April 28, at 10.30 a.m.

STAR ELECTRICAL ENGINEERING & MANUFACTURING COMPANY, LTD. W. R. Boyd, 67, Cleethorpe-road, Grimsby, appointed liquidator. Meeting of creditors at the Royal Hotel, Grimsby, on Friday, May 12, at 3 p.m. Particulars of claims to liquidator by July 1.

Bankruptcy Information.

MAYNER, Robert Victor, lately carrying on business at Narrow-street and Wentworth-street, Peterborough, electrical engineer. Receiving order, April 20. Debtor's petition.

MORRISON, Roy Thomas, 82, Lumb-lane, Bradford, electrical engineering contractor. Receiving order, April 22. Debtor's petition.

Notice of Intended Dividend.

DOYLE, Herbert, carrying on business as ACCESSORIES SUPPLY COMPANY, at 56, Hardman-street, Deansgate, Manchester, factor in electrical accessories. Last day for receiving proofs, May 10. Trustee, J. G. Gibson, Official Receiver, Byrom-street, Manchester.

Edinburgh Gazette.

BROWN (J. L.) & COMPANY (J. L. Brown, trading as), electrical engineers, 920, Pollokshaws-road, Glasgow. Estates sequestrated April 21. Meeting to elect trustee and commissioners on Friday, May 5, Faculty Hall, St. George's-place, Glasgow, at 12 noon.

HANNAH (A. W.) & COMPANY (Alexander Wilson Hannah and Thomas Hutton Scott, trading as), engineers' mill furnishers and electrical engineers, 46, Old Sneddon-street, Paisley. Partnership dissolved as at April 17, 1922, by mutual consent, by the retiral of T. H. Scott. A. W. Hannah will continue the business.

KELVINDALE ELECTRIC & MANUFACTURING COMPANY, LTD. Company to wind-up voluntarily. A. S. Brown, chartered accountant, 121, West Regent-street, Glasgow, appointed liquidator. Meeting of creditors at office of Wm. Murdoch & Son, solicitors, 98, West George-street, Glasgow, on Tuesday, May 9, at 12 noon.

SCOTTISH ELECTRIC LAMP REPAIRING COMPANY, LTD. Company to be wound up voluntarily. Meeting of creditors at the George Temperance Hotel, Paisley, on Monday, May 8, at 12 noon. R. Stephen Milne, C.A., liquidator, 16, Moss-street, Paisley.

Bankruptcy Proceedings.

WILLIAMS, Aneurin Tudor, and BEVAN, William John, trading as THE ELECTRICAL AND GENERAL ENGINEERING COMPANY, 49, Commercial-street, Aberdare. Liabilities are returned at £1 708, and there is a deficiency of £1 272. At their public examination debtors stated that they started business in partnership in December, 1919, with £100 capital, contributed in equal shares. For the first few months the business went on all right, but the moulders' strike in 1920 caused much difficulty in obtaining materials and involved them in loss of work. The coal stoppages of October, 1920, and April, 1921, also affected them, and later prices had to be cut considerably in order to meet keen competition. In August, 1921, they became aware of their insolvency, but they continued to trade and contract fresh debts in the hope that matters would improve. At this period they were asked by the bank manager to submit a statement showing precisely their position. In that statement they indicated that they expected to receive £1 212. This represented the total value of contracts plus their profits. They did not explain this to the bank because they thought the statement would be understood in that way. They denied, when closely questioned, that they had any intention to mislead. The examination was adjourned to enable debtors to amend their deficiency account.

Companies' Meetings, Reports, &c.

British L. M. Ericsson Manufacturing

Addressing the shareholders at the annual meeting of the British L. M. Ericsson Manufacturing Company last week, Mr. W. M. Crowe (chairman and managing director) said it was a pleasure to be able to come before them with a balance-sheet which, in spite of all the evidences of trade depression, was extremely satisfactory. If the Post Office would only now go ahead and place some orders for new material they might expect another good year in 1922, but as things were at present there was little in the shape of new orders coming from that quarter. One would have thought that, after so many years during which little was done in the way of telephone expansion, there would be sufficient work for all telephone manufacturers. But this was far from the case, every telephone factory in the country was not only working short time, but it had been necessary to part with a large proportion of the workpeople, thus adding to the long list of unemployed. Had it not been for the orders received from abroad their company certainly would have had to reduce their staff of experts, as well as the workpeople, to a minimum. Orders from abroad had, however, so far prevented this. They expected a few years ago that by this time operators would have been superseded by the automatic exchange system, but it appeared that they must wait for a few years longer before this system became common. Their Stockholm friends had received many orders for exchanges of their system of automatics. Their own company had the right to use that system, and they were not without hope that the British Post Office would give it a trial. They also had a system of automatics at Beeston factory which they hoped would make a mark in the telephone world. It was unlike any other system, and its working was much more simple than anything else so far invented. An abstract of the accounts appeared in our issue of April 14.

The net income of the American Waterworks and Electric Company for 1921 amounted to $724 493.

The Kaministiquia Power Company announce a quarterly dividend at the usual rate of 2 per cent. on the common stock.

The Montevideo Telephone Company has declared an interim dividend of 6 per cent. per annum, tax free, on the ordinary shares.

The directors of the Ever-Ready Company (Great Britain), Ltd., recommend the payment of a final dividend of 5½ per cent. on the preference shares, making 9 per cent. for the year, and 9 per cent. on the ordinary shares.

The Stock Exchange Committee have ordered 248 075 £1, fully paid, ordinary shares of the Brush Electrical Engineering Company, and £535 000 7½ per cent. prior lien debenture stock of the Lancashire Electric Light & Power Company to be quoted in the Official List.

The directors of Bell's United Asbestos Company recommend the payment of a balance dividend of 1s. 6d. per share on the ordinary shares, which, with the interim dividend paid in October last, makes a total distribution of 10 per cent. for the year. The amount to be placed to reserve is £8 000, and the sum of £34 013 remains to be carried forward.

The directors of the Calcutta Electric Supply Corporation recommend the payment of a final dividend on the ordinary share capital of the company, for the half-year ended December 31, 1921, at the rate of 6 per cent. actual, making 10 per cent. for the year, plus a bonus of 1 per cent. Relief will be given as heretofore in respect of Indian taxation.

The Board of Referees appointed to deal with Excess Profits Duty have, on the application of the Para Telephone Company, ordered that the statutory percentage as regards the business of supplying public telephone service in Brazil shall be 7½ per cent. in the case of a company or other body corporate, and 7½ per cent. plus 2 per cent. in the case of any other trade or business.

The directors of the Oriental Telephone & Electric Company recommend the payment of the following final dividends for the year ended December 31 last: 3 per cent. on the preference shares (less income tax), making a total of 6 per cent. for the year; 6 per cent., on the ordinary shares (free of income tax), making a total of 10 per cent. for the year, free of tax; and a bonus of 2 per cent. on the ordinary shares, free of income tax.

The report of the North of Scotland Electric Light and Power Company for 1921 shows a credit balance of £7 776, which, with £634 brought forward from last year, leaves £8 410 to be dealt with. The directors recommend the payment of a 10 per cent. dividend on the preference shares, absorbing £2 500; 1¼ per cent. dividend on the ordinary shares, absorbing £625; placing £4 500 to renewal reserve account, and carrying forward £785.

Presiding at the annual meeting of the British Automobile Traction Company last week, Mr. C. Shirreff Hilton said that the past year had been one of the most successful in the history of the company. Including the amount brought forward, there was a surplus of £49 637, out of which it was proposed to place £10 000 to reserve and to pay a dividend of 10 per cent. on both the participating preference shares and the ordinary shares, carrying forward £19 706, subject to Corporation Profits Tax. The net traffic receipts and other revenues amounted to £56 269, compared with £44 932 in the previous year. Administration and general expenses showed an increase of £867, which, in view of the largely increased turnover, was a very small percentage.

The accounts of the British Electric Transformer Company, Ltd., for the year ended Dec. 31, 1921, show that, after paying all manufacturing costs and expenses of administration, there remains a net profit of £91 416 10s., to which is added the amount brought forward from last year (£6 178), making a total available balance of £97 594 10s., which the board recommend be allocated as follows: To reserve account, £15 000; to depreciation reserve, £4 000; to payment of preference dividend of 7 per cent. for the year ended Dec. 31, 1921, £21 000; to payment of a dividend of 10 per cent. on the ordinary shares (3 per cent. of which was paid as an interim dividend on Sept. 1, 1921) and bonus of 2½ per cent., £40 625; to extra remuneration to the directors in accordance with the articles of association, £4 261 6s.; leaving 12 708 4s. to be carried forward.

The net revenue of the River Plate Electricity Company for 1921 (including arrears of interest for the years 1914-19 upon the 5 per cent. obligations of the German Trans-Oceanic Electric Company, £35 458) amounted to £80 693 (against £62 025), and the sum bought forward is £6 982. The directors have transferred £30 000 to general reserve, as well as other sums amounting to £10 654 held in suspense to cover certain contingencies, and that fund now totals £161 234. A dividend is proposed of 7 per cent. for the year on the ordinary stock, a sum of £10 000 is reserved for taxation, and £9 105 is carried forward. For 1920 the dividend was at the same rate. The directors propose to increase the capital to £500 000 by the creation of 25 000 ordinary shares of £1 each, ranking in all respects *pari passu* with the existing ordinary stock and shares. It is further proposed to capitalise £49 573 of the reserve fund and to issue 49 573 fully-paid ordinary shares of £1 each to the stockholders in the proportion of one ordinary share for every £6 stock held.

Meetings of the Southern Brazil Electric Company six per cent. mortgage debenture holders, eight per cent. 10-year noteholders and shareholders are to be held to-day (Friday) to consider a scheme of arrangement which provides as follows:—(1) The redemption of the first debentures to be suspended for a period of four years; (2) the £182 800 eight per cent. notes to be converted into £182 000 ten per cent. cumulative preference shares, ranking for dividend as from July 1, 1926, and preferential as to repayment of capital and arrears of dividend in a winding-up. In consideration of the noteholders agreeing to forego dividends up to July 1, 1926, the preference shares are to carry a cumulative dividend of 10 per cent. as from that date, and no part of the profits earned prior to July 1, 1926, is to be applied in payment of dividends on the ordinary shares without the sanction of a separate meeting of the preference shareholders; (3) the present paid-up share capital —namely, £650 000—to be reduced by 50 per cent., making the present £1 shares 10s. shares fully paid, and the amount thus written off—namely, £325 000—with the whole or part of the sum of £70 050 standing to debenture redemption reserve, together £395 050, to be utilised for writing off or writing down the following:—The debit balance on profit and loss account to Dec. 31, 1920, of £37 850; the estimated loss for 1921, £30 000; preliminary expenses, £25 000; discount on issue of debentures and expense of further issue, £36 087; eight per cent. notes issue expenses, £440; depreciation reserve, to be applied in writing down investments and assets in Brazil, £265 673.

Prices of Metals, Chemicals, &c.

Tuesday, April 25.

Copper Sulphate.—Per ton £26 10s.
Boric Acid (Crystals).—Per ton £60
Rubber.—Para fine, 10½d.; plantation 1st latex, 8¾d

The metal prices are supplied by British Insulated & Helsby Cables, Ltd.

New Companies.

Bideford and District Electric Supply.

BIDEFORD AND DISTRICT ELECTRIC SUPPLY COMPANY, LTD. (181 201). Reg. April 19. Capital, £25 000 in £1 shares (7 500 preference and 17 500 ordinary). To acquire from S. I. Knill the rights, benefits, and interests referred to in three agreements, and to adopt three agreements with the said S. I. Knill, Crompton & Company, Ltd., and Bartlett, Bayliss & Company, Ltd., and to carry on the business of suppliers of electricity in Bideford and elsewhere. First directors: Major W. Ascott, E. W. S. Bartlett, J. U. Fulford, J. N. A. Houblon, Sir Robert M. Hyslop, H. N. G. Stuckley, and G. C. Smyth-Richards. Secretaries: R. and R. B. Blackmore. Registered office: Alexandra House, The Quay, Bideford, Devon.

James Gordon & Company.

JAMES GORDON & COMPANY, LTD. (181 247). Private company. Reg. April 21. Capital, £15 000 in 8 000 7½ per cent. preference shares of £1 each and 14 000 ordinary shares of 10s. each. To adopt agreements with J. Gordon and J. J. Lassen, and to carry on the business of founders, mechanical, electrical, and marine engineers, manufacturers of water turbines, governors, pipe lines, and other water-power machinery, &c. Subscribers: S. Pennells and B. H. Gower. Life directors: J. Gordon (chairman) and J. J. Lassen. Registered office: Windsor House, Kingsway, W.C. 2.

Instrument Screw.

INSTRUMENT SCREW COMPANY, LTD. (181 233). Private company. Reg. April 20. Capital, £3 000 in £1 shares. Manufacturers of screws and parts for electric and scientific instruments, and small engineering and scientific apparatus, &c., in the United Kingdom or elsewhere. First directors: E. Homberger (managing director and chairman), H. Booty. Secretary: H. C. Booty. Registered office: Stanley-road, South Harrow.

Kohler.

KOHLER COMPANY, LTD. Private company. Regd. April 20 by H. C. Davies & Son, 222, Strand, W.C. 2. Nominal capital, £10 000 in £1 shares. To act as agents, importers and exporters of goods manufactured or sold by the Kohler Company, of Kohler, Wisconsin, U.S.A.; to manufacture and deal in Kohler automatic power and light machines, plant and accessories, electrical and other machinery, internal combustion, gas, and other engines and dynamos, &c. First directors: W. J. Kohler, W. B. Clark, and J. Peacock. Registered office is at 329, High Holborn, W.C. File number, 181 235.

Level-Protractor Engineering.

LEVEL-PROTRACTOR ENGINEERING COMPANY, LTD. (180 100). Private company. Reg. April 12. Capital, £2 000 in £1 shares. Scientific instrument makers, mechanical, civil, and electrical engineers, &c. First directors: J. Sutter, E. H. Newton, and W. C. J. Schlie. Registered office: 3, St. Georges-terrace, Brearley-street, Birmingham.

Peacehaven Electric Light and Power.

PEACEHAVEN ELECTRIC LIGHT AND POWER COMPANY, LTD. Public company. Reg. April 21. Nominal capital, £20 000 in 15 000 10 per cent. preference shares of £1 each and 20 000 ordinary shares of 5s. each. To acquire certain plant and machinery and the right to supply electric light and power to owners, leaseholders, and tenants on the "Peacehaven" Estates and elsewhere, and to adopt an agreement with the South Coast Land and Resort Company, Ltd. First directors: Rt. Hon. Lord Teynham, C. W. Neville, and C. F. Gold. Registered office: 4, Vernon-place, W.C. 1. File number: 181 255.

Power and Traction Finance.

POWER AND TRACTION FINANCE COMPANY, LTD. Reg. April 20. Private company. Nominal Capital, £250 000 in £1 shares. To seek and secure openings for the employment of capital in any part of the world; to apply for and turn to account any Act of Parliament, decree, concession, right, or privilege; to carry on, finance, assist, or participate in trading, financial, commercial, industrial, manufacturing, mining, and other businesses, works, contracts, and undertakings, and to carry on business as exporters and importers of any articles, and as general engineers and contractors, and any business usually carried on by trust, finance, land, mortgage, and agency companies and bankers; to promote companies, to deal in investments and securities, and to acquire, construct, equip, administer, and control public works of all kinds. First directors: Wm. L. Hichens, Sir John Hunter, the Rt. Hon. Lord Meston, P. J. Pybus, Sir Hugh Read, Bt., and J. Sampson File number: 181 220.

Exhibition Notes.

The FOREIGN SAMPLES EXHIBITION, organised by the Department of Overseas Trade, is now held at 7-11, Old Bailey (first floor), E.C. 4 (Tel.: 1 866 City), where 13 500 sq. ft. of exhibiting space are available. It is open to British manufacturers only from 10 a.m. to 5 p.m. daily and 10 a.m. to 1 p.m. on Saturday.

An Exhibition of National Industries is to be opened in SANTIAGO on Sept. 16, under the auspices of the "Sociedad de Fomento Fabril" (Society for the Development of National Industries), and will remain open for two months. Exhibitors of machinery will be permitted to show samples of foreign manufacture, which will remain out of competition. British firms desiring to exhibit industrial or other machinery should communicate with their local agents, instructing them to make the necessary arrangements.

Arrangements for the Week.

FRIDAY, April 28th (to-day).

PHYSICAL SOCIETY OF LONDON.

5 p.m. At the Imperial College of Science, South Kensington, London. Papers will be read on :—

1. "The Position of Best Focus in the Presence of Spherical Aberration," by Mr. T. Smith, B.A.
2. "The Determination of the Absolute Stress-variation of Refractive Index," by Mr. F. Twyman and Mr. J. Perry.
3. "An Experimental Comparison of the Viscous Properties of (*a*) Carbon Dioxide and Nitrous Oxide, and (*b*) Nitrogen and Carbon Monoxide," by Mr. C. J. Smith.
4. Demonstration of the Optical Sonometer. by Mr. F. Twyman.

INSTITUTION OF MECHANICAL ENGINEERS.

6 p.m. At the Institution, Storey's-gate, St. James's-park. London, S.W. Paper entitled "An Account of some experiments on the Action of Cutting Tools," by Prof. E. G. Coker and Mr. K. C. Chakko.

ELECTRICAL POWER ENGINEERS' ASSOCIATION.

7 p.m. At the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London. Lecture entitled "Some Notes on the Design of Generating Plant," by Mr. C. F. Hewitt.

INSTITUTION OF ELECTRICAL ENGINEERS. (NORTH-WESTERN CENTRE.)

7.30 p.m. At the College of Technology, Manchester. Public Lecture on "Recent Developments in Atomic Research," by Prof. W. L. Bragg.

INSTITUTION OF ELECTRICAL ENGINEERS. (SCOTTISH CENTRE.)

7.30 p.m. At Technical Institute, Dundee. Paper entitled "Single and Three-Phase Alternating Current Commutator Motors with Series and Shunt Characteristics," by Prof. S. Parker Smith.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (NEWCASTLE-ON-TYNE).

7.30 p.m. In the Lecture Theatre of the Literary and Philosophical Society, Newcastle-on-Tyne. Paper entitled, "Corrosion—with Special Reference to the Ferrous Metals and the Deterioration of Ships," by Mr. A. Pickworth.

JUNIOR INSTITUTION OF ENGINEERS.

8 p.m. At Caxton Hall, London, S.W. Lecturette. "Some Notes on the Utilisation of Water Power," by Capt. H. Whittaker.

MONDAY, May 1st.

SOCIETY OF ENGINEERS.

5.30 p.m. At the Geological Society, Burlington House, London, W. Part II. of Paper on "The Testing of Small Electrical Plant," by Dr. C. V. Drysdale.

INSTITUTION OF ELECTRICAL ENGINEERS. (WESTERN CENTRE.)

6 p.m. At South Wales Institute of Engineers, Park-place, Cardiff. Paper on "Electric Motor Starters." by Mr. James Anderson.

TUESDAY, May 2nd.

INSTITUTION OF CIVIL ENGINEERS.

6 p.m. At the Institution, Gt. George-street, London, S.W. 1. James Forrest. Lecture entitled, "Some Post-War Problems of Transport." by Sir John Aspinall.

WEDNESDAY, May 3rd.

INSTITUTION OF ELECTRICAL ENGINEERS. (WIRELESS SECTION.)

6 p.m. At the Institution, Savoy-place, London, W.C. 2. Lecture on "Short Wave Directional Wireless." by Mr. C. S. Franklin.

THE INSTITUTION OF METALS.

8 p.m. At the Institution of Mechanical Engineers, Storey's-gate, London, S.W. 1. Lecture on "The Relation of the Elements," by Sir Ernest Rutherford. F.R.S.

THURSDAY, May 4th.

THE IRON AND STEEL INSTITUTE.

10 a.m. At the Institution of Civil Engineers, Great George-street, London, S.W. 1. Annual meeting.

FRIDAY, May 5th.

ROYAL SOCIETY OF ARTS.

4.30 p.m. At John-street, London, W.C. 2. Lecture on "Imperial Wireless Communication," by Prof. W. H. Eccles, D.Sc., F.R.S.

THE IRON AND STEEL INSTITUTE.

10 a.m. At the Institution of Civil Engineers, Great George-street, London, S.W. 1. Annual meeting.

INSTITUTION OF ELECTRICAL ENGINEERS. (LONDON STUDENTS' SECTION.)

7 p.m. At the Institution, Savoy-place, London, W.C. 2. Lecture on "Electrically Oscillatory Discharges." by Mr. R. P. Howgrave-Graham.

THE JUNIOR INSTITUTION OF ENGINEERS.

8 p.m. At Caxton Hall, London, S.W. Lecturette on "Gold Casting under Steam Pressure." by Mr. E. N. Ching.

EDINBURGH ELECTRICAL SOCIETY.

8 p.m. At Philosophical Institute, 4, Queen-street, Edinburgh. Annual meeting.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by MESSRS. MEWBURN, ELLIS & CO., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

COMPLETE SPECIFICATIONS.

142 126 DICTOGRAPH PRODUCTS CORPORATION. Telephone sets. (21/8/17.)
142 845 SIEMENS-SCHUCKERTWERKE GES. Reversing of alternating-current shunt motors. (8/4/14.) (Addition to 2 409/14.)
145 400 FILIPPO, H., LELY, JUN., D., & NAAMLOOZE VENOOTSCHAP PHILIPS' GLOEILAMPENFABRIKEN. Electric glow discharge lamps. (20/6/19.)
145 421 SIEMENS & HALSKE AKT.-GES. Vacuum electric discharge apparatus having an incandescent cathode. (31/5/16.)
145 468 SIEMENS-SCHUCKERTWERKE GES. Dynamo electric machines. (10/11/14.)
145 528 BOSCH AKT.-GES. R. Construction of commutators. (29/4/19.)
145 587 MARSOLLIER, C. J. Electrical connecting devices and lamp-holders. (8/2/16.)
145 741 CORADI, O., & BUCHLER, H. GRAF-. Magnetic work-holders. (19/6/19.)
146 241 SIEMENS-SCHUCKERTWERKE GES. Totally enclosed dynamo-electric machines. (7/10/14.)
146 311 KRUPP AKT.-GES. F. Arrangement for the excitation of continuous current generators in Ward-Leonard systems. (6/1/15.)
146 425 WESTERN ELECTRIC CO., LTD. Telephone exchange systems. (29/12/16.)
148 313 HUTH GES. DR. E. F., & LOEWE, S. Methods of and apparatus for wireless telephony. (28/11/16.) (Addition to 148 312.)
148 316 HUTH GES., DR. E. F. Device for checking and recording at the sending station messages transmitted by wireless telegraphy. (21/10/14.)
148 323 HUTH GES., DR. E. F. Vehicle stations for wireless telegraphy. (4/12/14.)
148 415 SIGNAL GES. Electro-magnetic subaqueous sound producer or receiver. (11/7/18.) (Addition to 147 935, modified by 148 411 and 148 413.)
148 528 CONRADTY, C. (Firm of). Bow collectors for electric vehicles. (17/6/18.)
148 531 CONRADTY, C. (Firm of). Bow collectors for electric railways in which the slip-piece is adapted to turn upon its longitudinal axis. (28/4/16.)
149 282 MARCONI'S WIRELESS TELEGRAPH CO., LTD. Reception of wireless signals. (28/7/19.)
149 351 ALBER, E. Electric batteries. (26/7/19.)
149 975 MASCHINENFABRIK OERLIKON. Synchronous motor for polyphase current. (26/8/19.)
151 253 TROST, S. O. E. T. Wireless telegraphy. (18/7/19.)
151 609 LAFEUILLE, J. L. Electrical resistances. (22/9/19.)
151 613 LA PICHARDAIS, D. M. G. R. DE. Electric switches. (23/9/19.)
152 345 ROHDE, F. Suspension insulators for electric wires and cables. (12/10/20.) (Convention date not granted.)
152 658 VOLET, R. A. L. Dynamo-electric machine commutators and similar electrical apparatus. (13/10/19.)
153 908 MASCHINENFABRIK OERLIKON. Electrical heating device. (13/11/19.)
154 908 SOC. FRANCAISE RADIO ELECTRIQUE. Means for regulating the frequency of alternating currents. (6/12/19.)
155 297 GES FÜR TEERVERWERTUNG. Process for the manufacture of furnaces electrodes of large cross-section. (27/11/19.)
156 673 BERGMANN ELEKTRICITÄTS WERKE AKT.-GES. Construction of conductors for electrical machines. (26/11/17.)
157 103 WEDERSTAND AKT.-GES. FÜR ELEKTRO-WAERME-TECKNIK. Frames for the windings of electric resistances or heating elements. (12/9/18.)
157 438 SOC. ANON. DES ATELIERS BRILLÉ FRÈRES. Relays and synchronised clocks or other apparatus actuated thereby. (26/9/19.)
160 799 LEVY, L. Electric oscillation generator. (29/3/20.)
160 813 COHN, SEN. A. (Firm of). Electric switching or like devices. (23/4/19.) (Divided Application on 147 949.)
161 954 ALLMÄNNA SVENSKA ELEKTRISKA AKTIEBOLAGET. Means for reducing the ground current in electric high-tension transmission systems. (16/4/20.)
161 983 BAYERISCHE VEREINSBANK. Electric fire, burglar and like alarms. (20/4/20.)
163 288 ADAMS, A. H. Telephone exchange systems. (13/5/20.)
163 298 METROPOLITAN-VICKERS ELECTRICAL CO. LTD. Electrical controllers. (17/5/20.)
163 324 SIEMENS-SCHUCKERTWERKE GES. Process and apparatus for connecting additional transformers to a supply circuit. (14/5/20.)
164 725 SOC. D'ELECTRO-CHIMIE ET D'ELECTRO METALLURGIE. Process for obtaining deposits of iron by electrolysis. (9/6/20.)
165 072 METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Control of alternating current electric motors. (17/6/20.)
166 878 METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Control of alternating current electric motors. (19/7/20.)
167 496 AKT.-GES. BROWN, BOVERI, ET CIE. Oil-cooled transformer boxes. (5/8/20.)
168 860 METROPOLITAN-VICKERS ELECTRICAL CO. LTD. Protective apparatus for electrical systems. (8/9/20.)
168 893 BRITISH THOMSON-HOUSTON CO., LTD. Electron discharge amplifiers. (29/10/13.) (Divided application on 147 148.)
169 936 RAPHAEL, F. C., & EDISON SWAN ELECTRIC CO., LTD. Means for fixing electric cables and wires. (22/11/20.) (Divided Application on 32 934/20.)
170 016 BROWNING, W. H. Electrically heated soldering irons. (16/7/20.)
170 021 MARKS, E. C. R. (Nagel Electric Co., W. G.) Electric measuring instrument. (7/4/20.)
170 039 HOLSLAG, J. Electrodes for electric arc welding and like operations. (4/6/20.)
170 043 MONNOT, J. F. Storage battery plates. (8/6/20.)
170 048 HACKETT, P. J. Signalling circuits, particularly applicable to telephony. (9/6/20.)
170 049 WALKER, C. L. Electric signalling or control systems. (10/6/20.) (Cognate Application, 15 692/20.)
170 052 BULLEN, A. G. & JENKINSON, R. L. Electric switch automatically operated by heat. (11/6/20.)
170 072 MACRORIE, A. K., AIREY, H., MORRIS-SHEARING, G., and MULLARD, S. R. Supports for filaments used in thermionic valves and similar apparatus. (7/7/20.)

APPLICATIONS FOR PATENTS

April 10, 1922.

10 117 A. C. BARTON & F. H. LEFFLER. Electric switch.
10 122 E. G. CRAVEN. Rheostat, &c.
10 137 W. MCGEE & SON & J. B. & T. WHITE. Enclosed electric machines.
10 142 J. H. REEVES & J. TAYLOR. Method of locking lamps to holders.
10 143 & 10 144 C. E. WOOD, H. R. JONES, & W. E. LAWTON. Lifting magnets.
10 146 F. RICHARDSON. Drying paper on fibre insulated cables.
10 188 W. G. TURNER. Instrument for indicating simultaneously values of two variable readings.
10 207 B. T.-H. Co., H. C. WHEAT, & W. MILLNER. Electric lamp fittings.
10 214 RELAY AUTO. TELEPH. CO. & B. B. JOHNSON. Automatic, &c., telephone systems.
10 215 SOC. D'ETUDES POUR LIASONS TELEPHONIQUES ET TELEGRAPHIQUES À LONGUE DISTANCE. Long distance telephone installations. (8/7/21, France.)
10 220 RANSOMES, SIMS, & JEFFERIES, & MOSSAY & Co. Controlling mechanism of electric vehicles.
10 224 SIEMENS & HALSKE AKT.-GES. Telephone systems. (9/4/21, Germany.)
10 234 W. H. CHRISTIE & F. N. DENISON. Electric recording and sounding device.

April 11, 1922.

10 243 W. P. DURTNALL. Electric locomotives, tramcars, road vehicles, &c.
10 245 A. C. BARTON & F. H. LEFFLER. Automatic switch.
10 246 C. H.-W. BROWN. Electrically heated treeing iron for boot manufacture.
10 257 F. A. MILWARD. Rotating contact switch for bayonet holder fitting.
10 282 A. J. GREGORY & J. NICOL. Electrically controlled indicating device.
10 300 J. K. CATTERSON-SMITH. Alternating current circuit models for educational purposes.
10 311 M. A. RENISON. Diaphragm for sound recording telephone instruments, &c.
10 343 A. H. MAITRE & V. H. G. MARTIN. Damping device for switch contacts for electro-magnetic vibrating members. (18/4/21, France.)
10 348 LANDIS & GYR AKT.-GES. Prepayment meters for electricity, &c. (12/4/21, Switzerland.)
10 371 CHLORIDE ELECTRICAL STORAGE CO. (Kershaw). Storage batteries.
10 373 A. MELOTTE. Electric brush holders, &c.
10 382 C. C. GARRARD, M. J. RAILING, & W. WILSON. Charging accumulators.
10 393 B. T.-H. Co. (G. E. Co.). Regulators for electron discharge devices.
10 397 E. F. WIEDERHOLDT. Means for connecting conductors to sparking plugs.
10 401 A. H. PEHRSON. Rotating or oscillating electric furnace plants. (12/4/21, Sweden.)
10 402 C. B. KERSTING. Holders and adapters for radio telephonic and telegraphic apparatus.

April 12, 1922.

10 421 FULLERS' UNITED ELECK WORKS & L. FULLER. Galvanic batteries.
10 427 J. A. DAVIES. Device for application of electric power to agricultural machinery.
10 462 G. H. MOODY. Thermionic valve holders.
10 469 SIEMENS BROS. & Co., H. T. BODY, & W. H. GRINSTED. Automatic telephone systems.
10 471 W. PRIOR & C. E. RILEY. Selenium cells.
10 472 W. SANDFORD. Battery lamp.
10 474 F. KRUPP AKT.-GES. Time switches. (23/5/21, Germany.)
10 480 AUTOMATIC TELEPHONE MFG. CO. & H. H. HARRISON. Transmission of telephone numbers, &c.
10 486 EDISON SWAN ELECTRIC CO. Advertising device.
10 498 & 10 499 J. B. TUCKER. Electric switches.
10 507 GENERAL ELECTRIC CO., LTD., & G. C. MARRIS. Telephone repeater circuits.
10 510 STERLING TELEPHONE & ELECTRICAL CO. Indicators for lifts, &c.
10 512 E. P. BARFIELD & L. W. WILD. Electric furnaces.
10 513 M. MORRISON. Rectifiers for electric currents. (12/4/21, U.S.)
10 518 H. PARODI. Contact rail for electric traction.
10 520 H. L. DOWN & W. A. HOLE. Electric discharge tubes.
10 525 F. HERNAMAN-JOHNSON. Single-flash radiography.
10 527 C. A. VANDERVELL. Electric installations on motor cars.
10 538 G. W. HUMPHRY. Devices for connecting electric wires, &c.
10 539 G. W. HUMPHRY. Electric wiring systems for lead-sheathed cables, &c.
10 548 A. HELFENSTEIN. Closed electric furnace. (12/4/21, Austria.)

April 13, 1922.

10 572 T. G. P. HEALEY. Electric horns.
10 580 J. CLEMENT & L. GILLARD. Electric switches.
10 585 & 10 586 J. A. CRABTREE. Electric switches.
10 598 J. F. SCHLEPER. Jointing electric conductors.
10 612 A. G. BULLEN & R. L. JENKINSON. Adjustable clips for electric wiring.
10 628 F. KRUPP AKT.-GES. Permanent magnets. (29/6/21, Germany.)
10 629 F. KRUPP AKT.-GES. Electric overload protective systems. (28/5/21, Germany.)
10 649 BUREAU D'ORGANISATION ECONOMIQUE. Cooling of electrical apparatus. (13/4/21, Germany.)
10 650 R. PECHKRANZ. Electrolysis of water.
10 656 N. TOGAMI. Distributing systems.
10 660 S. M. TOWNSEND. Electric cooking devices.
10 666 VICKERS, LTD., & J. ETCHELLS. Electro-magnetic regulating devices for dynamo electric machines.
10 671 FERRANTI, LTD., & A. H. HIGGS. Alternating current distributing systems.
10 674 CHLORIDE ELECTRICAL STORAGE CO. (Ford). Storage batteries.
10 677 SCINTILLA. Apparatus for preventing operation of electric appliances on motor vehicles (20/5/21, Switzerland.)
10 678 S. J. FROST. Incandescent lamps &c.
10 700 W. S. GRAFF-BAKER & E. T. BAOCK. Electric apparatus for producing Ozone.
10 704 B. T.-H. Co. & E. F. W. ALEXANDERSON. Radio transmitting systems.
10 714 H. R. WRIGHT. Circuit arrangements for electric relays.

The Editorial, Advertisement and Publishing Offices of "THE ELECTRICIAN" *are at 8, Bouverie Street, London, E.C. 4. Telegrams: Benbrotric, Fleet, London. Telephone: City 9852 (5 lines).*

CONTENTS.

Notes of the Week.

The Budget.

Now that the first enthusiasm at the reduction of taxation has died down, the Budget is being criticised from a more sober point of view than was possible in the atmosphere of rumour and petition of a few days ago. A lower income tax and the postal and telephone concessions will mean a direct saving in industrial as well as private circles, and will, therefore, be all to the good, and the customs reductions, by lightening domestic expenditure, may assist in the revival of other branches of trade. The taxpayers of the country ought therefore to be thankful for what they have been given, but the fact remains that they are not thankful, and are eager for still further reductions. There is justice in the claim. For it will be agreed that after nearly four years of peace the burden of taxation is much too heavy. Even now the income tax is at the very high figure of 5s., and for traders there is still that inequitable charge, the Corporation Tax, except in the case of public utility companies, who are, we are glad to see, exempted for another three years, though we hope it will have disappeared long before that. Postal and telephone rates ought to be still lower, and many of the other taxes are unjustly heavy and are becoming increasingly difficult of collection. Even the concessions have only been possible by the adoption of methods which are not too sound, and it is a gamble whether details on both sides of the balance-sheet will come out at anything like the figures estimated. The cure of all these ills is, of course, reduced expenditure, but this is a policy which the Government are as unwilling as ever to adopt. It is not surprising then that the Federation of British Industries are demanding another "Axe" Committee, or that Mr. Bonar Law should say: "The main duty of the Government is to realise that the revenue will fall, and that everything that human energy can do should be done to keep our expenditure at the lowest level."

D

The Protection of Turbo-Alternators.

The Paper on "Protective Apparatus for Turbo-Alternators," by Mr. J. A. Kuyser, which has been read and discussed before various centres of the Institution of Electrical Engineers during the past few weeks, deals with a subject which is not only important in itself, but upon which most electrical engineers have decided views. It is not, therefore, surprising that the discussions generally were interesting, critical, and well sustained. Mr. Kuyser argues that, for economic and operating reasons, turbo-alternators must be protected, and that it only remains to determine what system of protection to use. Most of the existing systems have their drawbacks, and he, therefore, proposes a new method for overcoming these. Coupled up with this is a consideration of the phenomena which occur when the field system is opened, and the different methods at present in use also come in for criticism. A great part of the discussion was influenced by a natural desire to controvert these arguments, and we are led to the opinion that while no doubt turbo-alternators can be protected, there is no general agreement as to how it can best be done.

Why Protection at All?

The most interesting part of the discussion dealt, however, with another phase of the subject. Why, said more than one speaker, have protection at all? Design your machine, both mechanically and electrically, to withstand all conditions, and then discard all external aids to safety. To do otherwise is a confession of failure. In any event, it is a bad policy to hang about your turbo-generator, which is, after all, a more or less engineering job, all sorts of flimsy apparatus, which will probably fail when they are most required. The operating engineer is particularly insistent on this argument, which must not be considered simply as a survival from the days when circuit-breakers were tied-up with string.

Insurance Not Engineering

The question is one rather of insurance than engineering. If at the present time we know all there is to be known about the vagaries and effects of short-circuit phenomena, then it is surely better to design self-contained plant to withstand those conditions. If we do not it is better to insure expensive plant by providing it with protective apparatus. But as time goes on the progress of both these schools must be toward each other, and when they meet protective apparatus will have become very simple, if it is not unnecessary altogether.

Education Estimates.

The discussion on the vote for the Board of Education, which took place in the House of Commons last week, brought out the fact that the total amount allocated for education in the current year is £6 104 653 less than in 1921-22, but this saving is unfairly distributed over elementary and higher education and research. It is unfortunate that the financial condition of the country necessitates drastic cuts in the amounts allocated for the education services, but, in our opinion, these economies should be effected in such a manner as to cause the least damage to educational progress and efficiency. On the ordinary services of the Board of Education it is proposed to spend about £4 900 000 less than in the past year. This represents a cut of about 10 per cent.; but the grant to universities and university colleges is down by £300 000, or a reduction of 20 per cent., and there is a similar cut in the grants for technical colleges. There is to be a further saving of £118 486 on scientific and industrial research, or a cut of 28 per cent., and as there was a substantial reduction in the amount allocated for research last year, it looks as if it were intended that this imporant work should be left to private initiative and enterprise, and therefore we shall soon be again enjoying easy-going pre-war conditions. The lessons taught by the War are in danger of being lost, and higher education, technical training, and research are to be sacrificed for the sake of economies which do not in the aggregate amount to a half-million! In our opinion, this is not economy; it is a reckless disregard of the best interests of the nation and of the Empire.

Hot and Cold.

We have indicated above the attitude of the Government towards technical education as evidenced by the tightening of the national purse strings. But this apparently is not the attitude of Mr. Herbert Fisher, the Minister for Education. Speaking at the first of a series of lectures on "Physics and Engineering Science," which are being delivered before the Institute of Physics by Prof. A. Barr, Mr. Fisher said "the industrial progress of the country was insecure unless it was based on a wide knowledge of science. . . . Science, and science alone, could enable us to maintain and extend our industrial progress." We suppose that to the educationist turned politician this is an excellent argument for reducing the support given to technical education. But if Mr. Fisher really feels like that, and the education estimates are passed as they stand, he ought to resign.

Foreign Engineering Contracts.

Any organisation which helps to develop the export trade of the country deserves encouragement and support, and therefore we welcome the formation of the British Power and Transport Finance Company, which is primarily intended to obtain and execute comprehensive engineering contracts, involving civil, mechanical and electrical work. There are a number of large railway, hydro-electric, and harbour schemes in prospect, but contracts for these are usually let subject to conditions as to finance and date of completion, which preclude individual firms from undertaking them. The new company has been formed in order to overcome these difficulties, and it proposes to concentrate the experience and financial power of a number of engineering firms and financial organisations into one association. It will thus be in a position to undertake and carry out the largest contracts and projects. The directors of the new company are Mr. W. L. Hichens (chairman of Cammell, Laird & Company), Sir John Hunter (managing director of Sir William Arrol & Company), Sir George May (Prudential Assurance Company), Sir Hugh Reid (managing director of the North British Locomotive Company), Mr. John Sampson (director of John Brown & Company), Lord Meston (a director), and Mr. P. J. Pybus (managing director of the English Electric Company). It will be seen that the manufacturing resources of the companies concerned will be equal to any calls that may be made upon them, and the co-operation of engineering and finance, which is foreshadowed, should be capable of meeting the competition of any foreign amalgamation or combination.

The Lighting of Hospitals.

Advances in technical equipment and method in hospitals during recent years have no doubt been considerable, but it would appear, from a discussion before a joint meeting of the Illuminating Engineering Society and the Royal Society of Medicine on April 27, that the methods of lighting employed in these institutions are not always ideal. Mr. John Darch, who read an introductory paper, even warned the audience of Florence Nightingale's trenchant observation that "the very first requirement of a hospital is that it should do the sick no harm!" One of the commonest faults, according to Mr. Darch, in the lighting of hospital wards is the liability of the lights to distract the eyes of patients, owing to the glare from imperfectly shaded filaments within the range of vision. We have no doubt, however, that the problems only need to be clearly stated to receive attention, and the intention of the Illuminating Engineering Society to form a small joint committee to deal with them should have good results.

Illumination of Operating Tables.

Methods used in operating theatres show great variety, some being extremely elaborate, others rather makeshift. The lighting of the operating-table is a difficult problem. A relatively high illumination, not less than 25 foot-candles, is needed. The lights should be so arranged that the surgeon, bending over the table, is not hampered by inconvenient shadows from his head or arms. Scrupulous care must, of course, be taken to avoid dust falling on the table, and accordingly some believe that lighting fittings should not be immediately overhead. Further, the use of lamps of high candle-power is apt to engender an amount of heat, which is trying to the surgeon and possibly harmful to the patient. One interesting possibility mentioned in the discussion is the use of "artificial daylight" in cases where the correct judgment of colours is important. This occurs, for instance, in certain operations, in examining affections of the skin, and in bacteriological work. The lighting of microscopes, touched upon by Mr. Conrad Beck, is again a special problem to which alone an evening's discussion might be devoted. Another feature of hospital lighting is the necessity for providing

plug outlets for inspection lamps, the design of which also presents interesting optical problems. It is not easy to get a sufficiently intense and even illumination from a lamp capable of being run on an ordinary supply voltage, but some new forms of compact lamps shown at the meeting suggest that considerable progress has been made in this direction. The discusssion raised many interesting points, and should form a useful basis for further research.

The Engineering Dispute.

Two important events in the history of the engineering dispute have occurred during the past week. The Government have at last appointed Sir. Wm. Mackenzie to hold a Court of Inquiry under Part II. of the Industrial Courts Act, and the employers announced that the shops were to be opened from Wednesday to those men who undertake to conform to certain instructions. It is too early to say what will be the result of these moves, but we hope they will both bring nearer the settlement which is urgently necessary. We are glad that the inquiry will be open to the Press and to the public, so that as much light as possible may be thrown on the arguments of both parties. There is not wanting the feeling that something is being kept back, that selfish interests are being used to prevent agreement, and that politics are being allowed to prevent production. At a time when trade revival is necessary and possible this should not be allowed.

The Institution Council.

The general body of members having exercised their right to make further nominations to some purpose, the election of the Council of the Institution of Electrical Engineers this year promises to be hotly contested. In addition to the six official nominations for three vacancies among the members of the "Ordinary Members of Council," three unofficial nominations have been made, so that voters will have to erase no less than six names from the ballot-paper. The three additional nominations are Mr. R. A. Chattock, city electrical engineer, Birmingham, who is nominated by an influential Midland group, Mr. R. H. Fletcher, of Cardiff, who obtains similar support from South Wales, and Mr. A. M. Sillar, who receives recognition from both London and Manchester. If all these candidates are elected the local centres will have no right to complain of under representation. Mr. A. F. Harmer is also nominated for a vacancy among the associate members, but here no erasion is necessary. Mr. Harmer has done good work, both in public and private, in connection with the informal meetings, and we are glad his activities will now have wider scope. All that remains is to recommend members to show their interest in Institution affairs by voting, so that the Council, as elected, may truly represent the general body of the Institution.

Revision of Prices.

It is announced that the Electricity Commissioners have granted, and the Ministry of Transport proposes to confirm, the Special Order amending the Brechin and Montrose Provisional Orders. The announcement has aroused considerable feeling in the municipal circles of the affected burghs, and opposition to the Special Order will be continued, though, we hope, without success. The attitude of these Scotch municipal fathers is unreasonable, for they are really endeavouring to enforce rigid agreements entered into and orders issued in the year 1898. The maximum price was then fixed at 8d. a unit, but two years ago permission was obtained under the Statutory Undertakings (Temporary Increase of Charges) Act, 1918, to raise the charge to 1s. a unit for private supply. The company now desires to make permanent provision for the periodical revision of the charges, somewhat on the lines of the Electricity (Supply) Bill, and the Commissioners have, naturally, granted the application, which is quite a reasonable one, and will operate as much in favour of the consumers as the company.

Bumbledom à l'Ecosse.

The contention of the Brechin Council is that as they transferred the original Order to the company on special terms as to the charges for electricity, "they should have the absolute right to fix prices without the interference of the Electricity Commissioners," and they would, therefore, like to limit the company to the pre-war dividend, which was only about $1\frac{2}{3}$ per cent. We doubt if the Council could have made a greater success of the undertaking than the company, but if they think they can we feel sure they can obtain possession of it upon reasonable terms. Many of the old provincial provisional orders were transferred to or secured by companies upon harsh terms, and it is for the good of the industry as a whole that these should be now revised, so that a reasonable return may be earned on the capital invested.

The Indo-European Telegraph System.

There is now a good prospect of the telegraph service of the Indo-European Telegraph Company, which has been completely interrupted for nearly eight years, being restored, as the company has secured the necessary concessions from Germany, Poland, and the Soviet Republic of Russia, the latter having been signed on April 12. Substantial progress has also been made with the work of repairing and renewing the telegraph poles and lines. Parts of the system, especially in Poland, have had to be rebuilt, and the task of restoration has been difficult and costly. However, we congratulate the company upon the success of their long and delicate negotiations, and we hope that their telegraph service to the Near East and India will soon be available for commercial and business purposes. It will add greatly to the existing telegraph facilities, and, by giving an alternative route to India, will relieve the congestion on the Eastern Company's cables, and thus minimise the risk of delays to Indian and Eastern cablegrams. Though the company has not been earning anything since the outbreak of the War, dividends have been regularly paid, as a joint purse arrangement exists with the companies engaged in the Eastern business, and there was also a substantial dividend equalisation fund. The latter, however, is now exhausted, but as the current year should see the company again earning money from international traffic, the return to the shareholders may not suffer in consequence. We notice that the Odessa-Constantinople cable is in working order, and this is a good augury, for we believe it portends the extension of the service to Southern Russia, the Black Sea ports, and the adjacent territories.

"The Electrician" and the British Museum.

A pleasant task, which hardly a day passes but we are called upon to perform, is to advise readers of the whereabouts in ancient Electricians of some article whose contents will prove useful to them in their present work. This pleasant task is, however, not without its unpleasant corollary. For we are often unable to supply the particular copy demanded—a copy which may be dated ten years ago, fifteen years ago, or even in the early 'nineties. We are, therefore, grateful to a correspondent, well known in newspaper circles for his research work, for pointing out that

The Electrician has been regularly filed and bound at the British Museum since its issue of May 25, 1878, thus providing what can only be described as a wonderful budget of electrical history.

The Law and its Application.

To those who have anything to do with publishing this may not seem extraordinary, but although it has been the law since the early 'forties that a copy of every newspaper, book, or pamphlet publicly offered for sale should be forwarded to the British Museum, that statute until comparatively recent times was more honoured in the breach than the observance, so that there is but a small minority of periodicals of which anything like a complete file exists.

"There is no doubt," our correspondent continues, "that when the paper first came into existence it supplied, to use a hackneyed phrase, 'a long-felt want,' and a study of these priceless volumes shows that from 1878 The Electrician had its fair share of public support and advertising patronage, both of which, as the years have gone on, have continued to increase, until it has become a question, the war notwithstanding, whether at any time your periodical ever enjoyed so large a measure of popularity as it owns to-day."

Seekers after electrical truth, as mirrored in the columns of The Electrician, will, therefore, be glad to know where they may refer to a complete file of all our issues, always excepting those less than a year old, which, by the rules of the Museum, may not be inspected. It may be added that very complete files of The Electrician are also to be found in other places in London and the provinces, notably in the libraries of the Institutions of Electrical and Civil Engineers and at the Patent Office.

Switchgear Evolution.

The details of the evolution of switchgear design and construction form an interesting chapter in electrical history. In the early days, when low voltages were general, heavy currents were broken in air by means of hand-operated switches, which made connection on rubbing contacts of elemental simplicity. Conductors were festooned about these switches in a manner more artistic than safe, and the fires which naturally were not uncommon were extinguished by drastic, though effectual, means, which, however, carried wreckage in their train. The switchboards themselves were, of course, fixed in buildings to protect them from atmospheric influences, but in other ways protection, as it is understood to-day, was conspicuous by its absence.

First Steps Towards Safety.

As the operating voltages increased, a movement towards a safer condition of things was made in two ways. First the switches themselves were placed in separate compartments or cubicles and other live-metal work was protected from unauthorised contact by barriers of suitable design. Then with the coming of the oil switch the contacts at which the circuits were broken were themselves protected and the equipment itself was fixed in places remote from human contact under normal conditions. This stage in evolution was a step towards greater safety and certainty in operation, but at the same time was a step towards greater complication.

The Coming of the Ironclad Switch.

The ironclad switch, which may be said to form the next stage, was therefore a step in that cyclic change towards simplicity which is characteristic of all engineering advancement. This switch, by concentrating the protection afforded, at the same time eliminated many complications and allowed the production of a type of equipment which was not only electrically safe and mechanically sound, but was immune from atmospheric influences in a way which was not thought possible in the early days of the rubbing-contact switch. In other words the ironclad switch was a self-contained piece of apparatus which could be used anywhere and for any purpose.

A Courageous Step.

These conditions led quite naturally to a further step forward. It was a step which was taken with so much diffidence that Mr. Coates, in an article on the subject which we publish on another page of this issue, is quite correct in calling it courageous. It was in fact nothing less than placing oil-break switchgear out of doors and so saving not only the cost of sub-station buildings, but gaining advantages from better observation and greater security. This was indeed a great step forward. Twenty years ago it was a step which would have been regarded with horror, and even ten years ago it was considered a fit subject for comic treatment. At present it may be stated with truth that the outdoor sub-station has come to stay. For while not much progress has been made with its application in this country, that is more due to our conservatism and to other conditions that have more recently influenced electrical progress than to anything inherently wrong with the outdoor sub-station itself. For in the United States, where the climatic conditions are, if anything, worse than in this country, and on the Continent it has been largely developed with considerable success. This development has also been helped by an abatence of the restrictions we labour under in this country.

Insulation the Deciding Factor.

The details which Mr. Coates gives in his article make it easy to see why this should be so. The whole problem is insulation. And transmission lines at pressures exceeding anything we have considered for practical purposes in this country have long been used with success elsewhere, so that the insulation problem has been solved. That disposes of everything but the switches, and in them, as Mr. Coates points out, insulation is a mechanical rather than an electrical matter and in some ways becomes easier as the pressure is increased. Instrument transformers introduce some difficulties, but these can be overcome by the use of water-tight terminal boxes and careful workmanship, a remark we imagine which equally applies to the sealing off of the transmission cables where these are employed instead of overhead lines.

Even as regards the switches which introduce the only novelty into the situation, Mr. Coates points out that there is nothing to fear. As we have already stated the modern tendency is to place ironclad protection closely round the switches and to strip everything else away. From its design and construction, therefore, the standard oil switch seems quite applicable to outdoor work with the addition of larger clearances and a careful attention to such minor points as erection and painting. This attention is made easier by the fact that a greater generosity in space is generally permissible, though the total ground area of the two types of sub-station does not usually vary greatly.

An Idea Worth Consideration.

Economically, as Mr. Coates shows, in the details he gives of a 33 kV scheme, the idea is well worth close consideration. A number of alternative designs are of course possible, but in every case a saving amounting to about 25 per cent. of the total can be obtained by adopting outdoor methods. This saving is, of course, obtained on the buildings alone, the cost of switchgear for outdoor work generally being rather more than for indoors owing to the reasons mentioned above. The difference is not, however,

important. These figures have recently been confirmed independently from the results of Swiss practice and indicate therefore that the question is one which, in these days of high voltages and linking up, should be closely considered by our electricity supply engineers.

It is also a question which should be closely considered by designers and manufacturers. For like many other branches of electrical progress the evolution of outdoor switchgear has largely been in the hands of American and Continental engineers. Conditions over here are not, however, the same as in these two countries, and it will be necessary to strike out a line for ourselves. We are glad to think that this is being done.

Transport Problems.

"Michael Angelo," remarked Sir John Aspinall in the James Forrest Lecture which he delivered before the Institution of Civil Engineers on Tuesday, "once said: 'Little things make perfection, little things mar perfection, and little things are the greatest part of perfection.'" The lecture dealt with "Some Post-War Problems of Transport," and ranged big and large over the many phases of this important question, which, as the lecturer pointed out, has been tackled with enthusiasm, vision and wrongheadedness at various times since 1855. All these attempts at solution are, however, alike in two things: they all envisage the enormity of the work and the great costliness which any scheme of improvement will involve, and they have all been pigeonholed in somebody or other's desk. And still the London traffic problem grows like an abnormal infant, gaining power and strength every day, and still optimists and lecturers, at loss for a subject, put forward schemes for its solution. But nothing is done, and it does not look as if anything ever will be.

Herculean Qualities Required.

This is not to say that Sir John Aspinall's address is not worth study. It is very much the reverse. It is worth study because it brings out so clearly how Herculean must be the qualities of the man who undertakes to summon order out of the chaos of London traffic, and how little the much-vaunted increased facilities have contributed to bring about any improvement. It might indeed be said that these facilities have made matters worse. They have encouraged travelling and increased the flow of traffic at a greater rate than the means provided for dealing with that flow. This, of course, is not the whole story. For the conversion of London into a workshop with its dormitories outside has not been entirely caused by the larger number of trains (not the greater ease) provided for travelling to and fro, though the two movements are inseparably bound up. Both have increased the difficulties which were so obvious in 1855, and even earlier, that suggestions for their improvement were already being made. And it is a little difficult to see how matters can be improved.

Cold Comfort for the Suburbs.

For, preaching on the text we have already quoted, Sir John Aspinall has but cold comfort for the suburban passenger. Matters might be bettered, he thinks, by more attention to the methods of platform approach, by the use of plain, well-lighted direction signs, by the better design of rolling stock, by thinking out other methods than those employed for supporting standing passengers, by constructing separate platforms for entrance and exit, and so forth, and so on. But he says: "It is a mere utopian vision to hope that seating room can ever be so ample that straphanging will be abolished in rush hours," and those whose daily travel is by means of that suspensory and uncomfortable method, while thanking Sir John for making their treadmill more scientific and luxurious, may well think modern engineering barren if this is the best it can do for them.

New Lines Wanted.

The difficulties, which Sir John suggests might be solved by the above methods, are nevertheless very real and are becoming every day harder to solve. As we have already pointed out, the schemes for linking up existing suburban systems, though good in themselves, will only mean greater congestion on the central lines, and will therefore tend to make travel more crowded, more troublesome, and less speedy than it is at present. The only real solution for this is the construction of relief lines designed, not for the present-day traffic but for future traffic, and built in the light of experience to include all the time-saving devices which we now know to be necessary. Especially might an outer-circle railway be built on which goods and passengers between two outlying districts could be carried without coming into the central area. To undertake such relief work will require courage and money, but it will in the long run provide a truer solution of the difficulty than any attempt to improve existing methods.

In a greater or lesser degree the same problem is present wherever suburban traffic is handled, and the two most promising solutions are electrification and well-thought-out methods of handling the traffic with all that the phrase implies. Electrification, as Sir John rightly points out, is, for economic reasons, also the best way of handling the main line traffic problem.

Another Solution.

There is one aspect of the traffic problem, which Sir John touches upon by inference, which may in due time prove to be the right road for escaping from many of our present difficulties. A large amount of our railway and road traffic is indispensable in order that the government and industry of the country may be properly carried on. But were our life ordered differently the traffic problem would also assume a different shape. At present a vast amount of train mileage is expended in taking passengers from their homes to their work and back again, in carrying goods from factories to distributing centres and then to the places where they are consumed. All this means a waste of time, rolling stock and energy, which has to be put down in plain figures to be believed. If this could be prevented, or at any rate reduced, one great section of the traffic problem would be solved almost by a stroke of the pen. In a word, if men and women lived where they worked we could reduce what are in reality unnecessary movements and give our present railway system a margin for useful expansion.

The Garden City Idea.

Sir John rather hints at some such solution in his remarks on the supply of electric current, and the idea is, of course, the essence of the garden city movement. If by the help of the Electricity Commissioners and the railway companies cheap electricity can be supplied along the length of our existing lines of communication the establishment of factories and dwellings under better conditions than we know at present would be easily possible. We should have a movement of divergence rather than concentration, a movement which should solve the traffic problem in the best possible way. Failing that it is a little difficult to see what can be done, especially in view of the reluctance of those most concerned to do anything but drift.

High Voltage Switchgear Design.

By W. A. COATES.

The problem of building electrical equipment for the high voltages which are now becoming common is mainly one of insulation. Two main types of insulation are required, that which merely supports the conductor and that which insulates the conductor where it passes through an earthed body. In high voltage work the limitations in design are mechanical rather than electrical, and in other ways greater simplicity is possible than at lower pressures. Though high voltage gear was at first contained in cubicles, it was soon found that this was unnecessary, while in 1908 the advantages of placing the gear out of doors was discovered. Mr. Coates discusses at length the details of modern outdoor switchgear compared with indoor equipment, and points out its economic and engineering advantages.

We have reached the stage in this country where it is necessary to reconsider the nomenclature applied to system pressures. This need is accentuated by the large Colonial developments and by the fact that certain British concerns are actively catering for this specialised market. The British Home Office rules have established the terms:

"Low Pressure" for systems not exceeding 250 V,
"Medium Pressure" for systems between 250 and 650 V,
"High Pressure" for systems between 650 and 3 000 V, and
"Extra-High Pressure" for anything over 3 000 V at the receiving point.

What, then, are we to call a system working at 66 000 V? Confusion has already arisen, due to the use of present phraseology, on systems which include high-voltage transmission, and it is suggested that the time is ripe for the adoption of some new term to meet the occasion. But superlatives in technical phraseology are undesirable, and in the title for this article the simple description "High Voltage" is applied to systems above the generating voltage. An adequate alternative term would be "super-generating pressure." This has the advantage of being self-explanatory, although it may perhaps be a trifle indefinite. There are systems which generate at 650 V or 2 200 V, and then step-up to 6 600 V for transmission.

The great majority of the world's high-voltage transmission systems are in North America, and it is a natural consequence that the two great American manufacturing concerns have led the way in the construction of suitable transforming and switching apparatus. Between them they have probably built 75 per cent. of the high-voltage equipment in the world, the balance having been supplied by some half-dozen Continental manufacturers. Within the past year at least one British concern (that with which the writer is connected) has entered the market and has laid down equipment enabling it to build apparatus for the highest commercial voltages.

Insulation and Switchgear.

Since high-voltage design problems are, in the main, insulation problems, a brief review of the position from that point of view is justifiable. Two main types of insulation are required: that which merely supports a conductor and that which insulates a conductor where it passes through an earthed body.

For indoor work, supporting insulators are comparatively simple to design and construct. The ordinary porcelain post insulator, proportionately enlarged, is customarily employed. Great mechanical strength is not of so much importance as on lower voltages, since the mutual repulsion between the conductors on short-circuit varies directly with the square of the current, and inversely as the distance between conductors. These tall porcelains can, therefore, be made hollow, with walls sufficiently thin to be thoroughly vitrified during the firing process. The longer insulators are usually thrown and turned in two parts, and are then jointed before fixing. To this there is no objection, since puncture-resisting qualities are not required.

Insulator Dimensions.

Full standards for insulator dimensions do not exist. In general, it will be found that for a given system voltage Continental insulators are appreciably shorter than those of British or American manufacturers. The following table gives usual values for the axial length of indoor post insulators:

Table I.

System kV.	Axial Length, inches.	
	British or American.	Continental.
22	9¼	7½
33	13	10
44	16	12
55	19½	14½
66	23	17
88	29	22
110	36	27

Profiles Adopted.

The profiles adopted for insulators of this type vary considerably, although irregularities are usually a matter of taste rather than scientific design. In fact, it is not infrequent for the addition of flanges or ornamental projecting rings to reduce the flash-over voltage of an insulator by providing points for stress concentration. The question of smooth versus corrugated surfaces has been thrashed out to a conclusion in favour of the former long ago. In their somewhat rare indoor installations, American designers still use corrugated high-voltage insulators, apparently because they do not consider the advantage gained sufficient to make it worth changing existing standards.

Insulators and Outdoor Work.

For outdoor work the problem is practically the same as for supporting the transmission line. The ordinary pin-type insulator ceases to be a commercial proposition on systems over 66 kV, as the size and weight of porcelain increase out of all proportion to the voltage. The unit construction—wherein several porcelain discs or sheds, separated by jointed metallic fittings, are used in series—is almost universal above that pressure, and is often employed for lower pressures.

Limitations Mechanical Rather than Electrical.

Where the busbars or connections can be suspended, the ordinary flexible string of line-insulators is employed. For holding the contacts of isolating switches, or other apparatus, rigid constructions on similar lines have been adopted. With these the limitations of design, so far, have been mechanical rather than electrical, although when working at 220 kV changes in the electrical design also may become necessary. In general, these tall, unit-type, post insulators should not be subjected to bending loads of any magnitude, but should rather be worked in compression, tension or torsion. Operated in this way no trouble is experienced.

Bushing Insulators.

Bushing insulators for high voltages are of three general types: (1) Compound-filled porcelain shells; (2) oil-filled porcelain shells; (3) condensers built of concentric layers of micarta, with metal-foil plates at intervals. To some extent bulk bushings made of bakelised micarta are employed also.

All three forms have been successfully applied to both indoor and outdoor working, the vast majority being of the oil-filled or condenser type. The former has the disadvantage of being somewhat delicate to handle, since at least one (usually three) oil-tight joint must be maintained, and, in the nature of things, the potential distribution across its surface is inferior to that of the condenser terminal. Against this, the porcelain shell can readily be moulded so as to incorporate rain-sheds for outdoor work, whereas separate sheds must be fitted over the condenser type.

For a given working voltage, the radial thickness necessary at the ground band is a maximum with the compound filled or bulk bushings, and a minimum with the condenser types. Ring-type transformers will thus be more accurate when used over a condenser than on any other type of terminal.

Apparatus Design.

Apart from the special design of terminal, to which reference has been made, and from the fact that greater clearances to earth must be allowed, there is little difference between the apparatus used on the highest pressures and that employed on our usual British voltages. The probable gas pressures developed in a high-voltage oil switch are less than with one on low voltage, so that the tanks, although much bigger, do not have to be stronger in proportion. When they are placed out of doors, the bottoms of all tanks should be raised sufficiently from the ground to permit the under-surface to be painted. This, of course, applies equally to power and instrument transformers.

Cost considerations prohibit the use of potential transformers on pressures over 66 kV. Metering can usually be done equally well on the low-tension side of a transformer bank. Some very desirable systems of automatic protection necessitate potential connections, but these must be put on one side in favour of protective systems, not quite so perfect, which can be worked from series transformers only.

Where the secondary load on series transformers is small, and the normal full load H.-T. current is of the order of 100 A, ring-type transformers round a condenser or oil-filled terminal can be used. The ring transformer is housed on the under-side of a switch or power-transformer cover, and thus takes up no extra space.

If conditions make wound primary series transformers essential, they are built as separate units, the two high-tension leads, lightly insulated from one another, being taken through the tank-cover in a single bushing. To avoid trouble, due to the inductance of the primary winding, when high-frequency surges occur, a shunt resistance is commonly bridged across the high-tension leads.

On all apparatus placed out of doors, to which small wiring is run, a watertight terminal box must be provided, with a downward outlet for screwed conduit. Plenty of space is desirable in such boxes, since connections may have to be changed or made with cold fingers.

Lightning Arresters Questions.

Lightning arresters for high-voltage work are a fit subject for a separate article, or indeed a book. It may be noted, however, that on pressures over about 50 kV neither the Wurts (multi-gap) type nor the condenser type are practical. The arresters in use are all either of the electrolytic type, or else a more or less elaborate modification of the original horn arrester. The chief point to be watched in installation is consequently the provision of adequate clearance above and around the horn gaps, since the arcs may rise to considerable heights.

There is a growing tendency to omit lightning arresters altogether on lines of 80 kV or more, and to rely solely on the protection of a ground wire run above the transmission lines. This is quite a logical proceeding, and has apparently been quite satisfactory on those systems treated in this way. Probably the majority of engineers will continue to instal the most efficient protective apparatus available, however.

Layouts.

In the layout of switching equipments marked variations occur in the practice followed in different countries. For apparatus working at generating voltage, some form of cellular construction is provided almost universally. In most large power-stations the fact of cubicle work being present does not materially increase the space occupied by the switchgear, since circuit centres are determined rather by the dimensions of the oil-switch. This does not hold good at super-generating voltages.

It is unsound to consider as an insulator the material of which cubicles are built, since in nearly every case such material is hygroscopic. It follows, then, that the clearance from live metal to cubicle wall must be as great as to earth. If the system be insulated, or have the neutral earthed through a resistance, it is necessary to reckon on the possible voltage to earth being the same as from phase to phase. The distance between conductors in different phases will thus be the thickness of the barrier which separates them, plus twice the air distance which would be safe were no barrier present.

Cubicle Design.

Cubicle work is intended (*a*) to limit the fire hazard; (*b*) to protect from adjacent live conductors men working on a dead circuit; and (*c*) where phase barriers are used to protect from accidental phase-to-phase short circuits.

The increased spacings essential with high voltages automatically reduce the risks under (*c*), and, to a degree, those under (*b*) also, leaving only the fire risk. Complete subdivision of phases is very rarely adopted on high voltages. Most Continental designers employ some cubicle work, applied like the flavouring in a cooking recipe, " to taste." There is no uniform practice. " A " employs full circuit barriers and also phase barriers between busbars. " B " does the same thing, but forgetting that fire control is the primary object of cubicle work, saves money by taking conductors through large holes in the cell walls, instead of through insulators which close the orifice. " C " encloses all the gear for a single circuit in a fire-proof room which is not subdivided in any way.

Safety Without Cubicles.

When American designers first approached this problem they took the bold step, and omitted all cubicle work. Safety was secured by guard-rails round the equipment for each circuit. The fire hazard was accounted negligible, for not only are accidental short-circuits less probable, but also

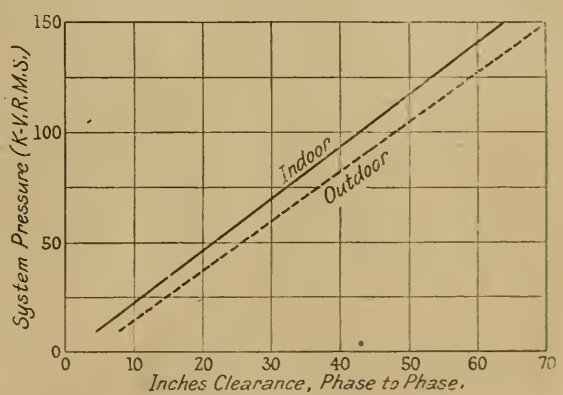

Fig. 1.

high-voltage oil-circuit breakers are less likely to burst when opening on short-circuit than those on lower voltages.

Experience has shown their action to be fully justified, as on these open structures very few accidents have happened which would have been avoided or minimised by cubicles. So far as the writer is aware, the sending and receiving stations on the Shawinigan system constitute the only outstanding exception to this practice. Here each circuit has its equipment in a separate fire-proof room.

Some of the most recent Continental installations have been planned to omit all cubicle work, and it seems reasonable to expect that in the comparatively near future cubicles will be confined to generating voltages only.

The Beginning of Outdoor Work.

In 1908 another courageous step was taken, when for the first time, oil-break switchgear was placed out of doors. The first large installation of this type was erected near Hamilton, Ont., Canada, in 1909. As an extra precaution, snow-sheds were erected above the oil-circuit breakers, but the first winter demonstrated conclusively, first, that the sheds did not protect the switch terminals from the snow, and second, that there was no need to do so, since they functioned just as well when buried in snow as when clean.

For outdoor work it is preferable to use rather larger clearances between phases and to earth than indoors. In Fig. 1 are indicated desirable standard clearances for the

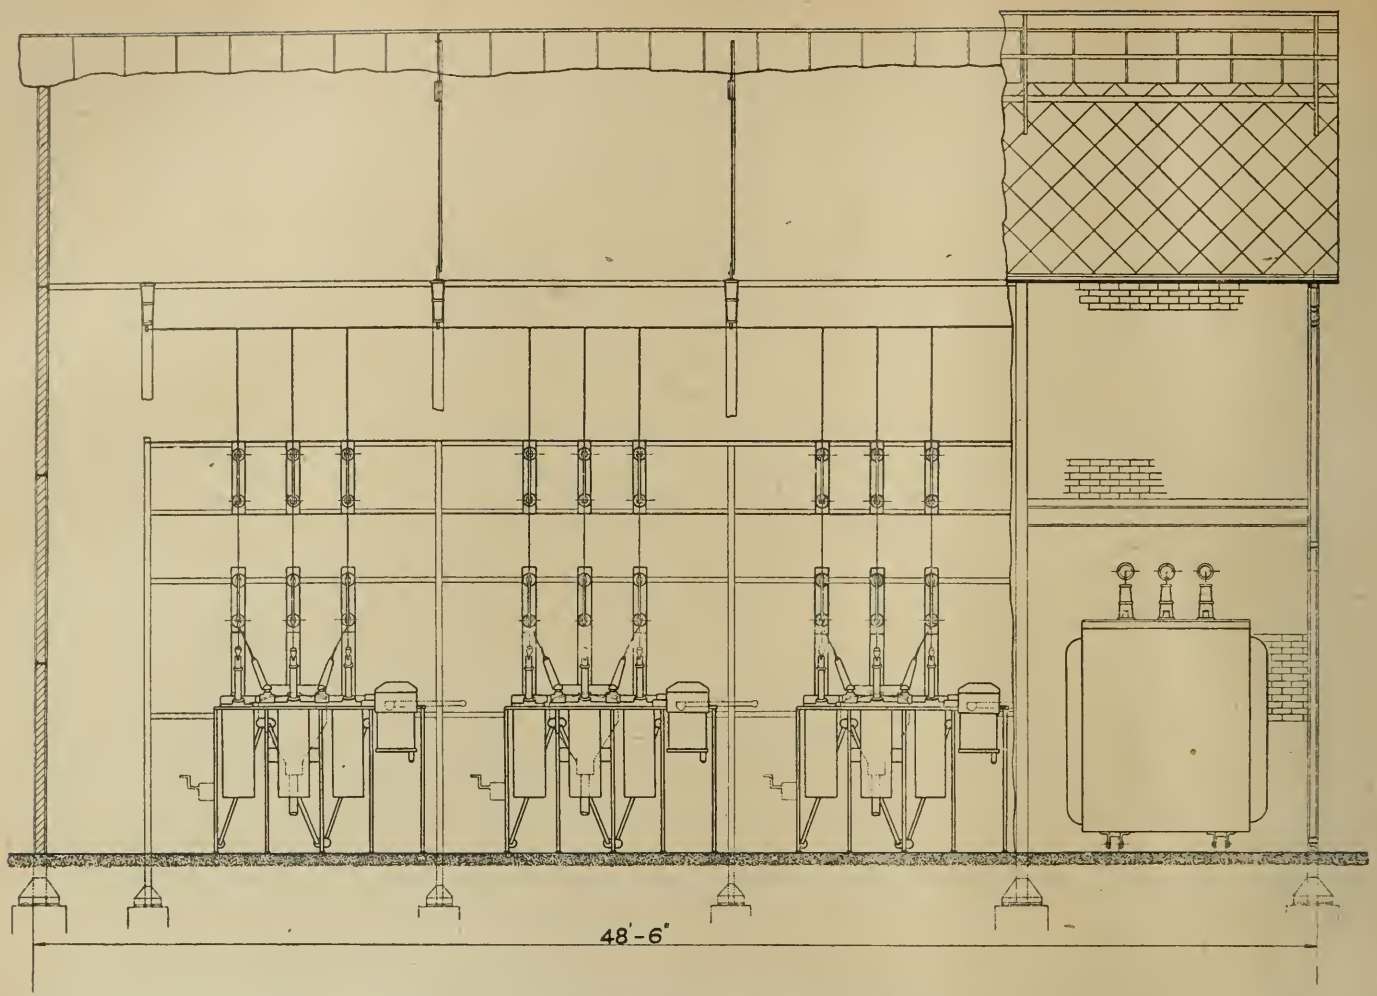

Fig. 2.—Exterior Elevation of Typical Indoor Sub-station, shewing Transformer in Cubicle, with Shutter of Latter Removed. Section "AA" shewing Feeder Switches.

two conditions. These are given for normally located installations at or near sea-level. Where the plant is at a high altitude the spacing should be varied inversely as the air density. For instance, at an altitude of 10 000 ft. the air density is 0·68, and the spacing should be increased by 47 per cent.

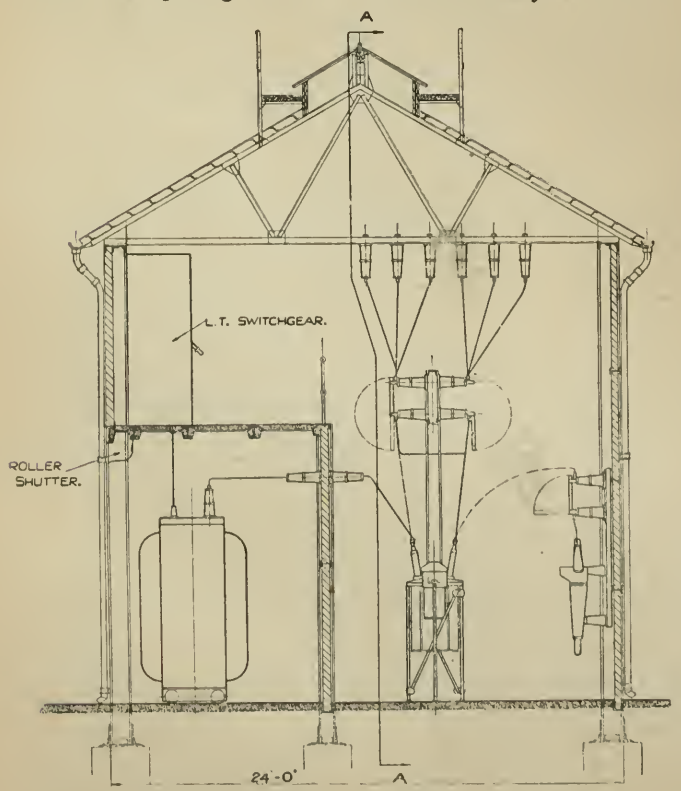

Fig. 3.—End Elevation of Typical 33 kV Transformer Sub-station.

As witness to the foregoing comments on the various types of layout, a large number of typical cases were studied recently, and the following approximate relationships determined for plants of pressures from 30 kV to 110 kV:

Type of Layout.	Per cent. Space Occupied.
Single bus, Continental cubicle layout ..	100
Double „ „ „ „ ...	115
Single „ American indoor „ ..	65
Double „ „ „ „ ...	65
Single „ „ outdoor „ ...	85
Double „ „ „ „ ...	140

Since cubicle structures for super-generating voltages may be regarded as obsolescent practice, it is proposed to discuss more fully the open indoor equipment as against the outdoor station.

The Space Question.

In the first case it will have been noted in the above table that the outdoor equipments occupy more space than those indoors. Primarily, this was not due to necessarily increased conductor spacing, but rather because, in the majority of instances, plenty of cheap ground was available. The whole outfit has been spread out for better and safer handling of equipment, and because so doing has not materially increased the total cost. As a rule, it is possible to get an outdoor switching equipment on to practically the same ground area as the corresponding indoor gear. This is demonstrated hereafter.

As regards cost, the equipment itself—*i.e.*, power transformers, oil switches, instrument transformers, and isolating switches—when built for outdoor service, will cost about 7 per cent. to 10 per cent. more than the corresponding

indoor types. This ratio being approximately fixed, in the typical cases following only the costs of buildings or steel-work structures are separately estimated.

Outdoor equipments at generating voltages are not usually feasible, since the space occupied is greater than with indoor equipment. In two cases recently studied, where the pressure was 11 kV, the outdoor scheme required two or three times the space of an indoor equipment, although there was an appreciable price advantage in favour of the former.

A further point is that on the L.-T. side quite an array of instruments is required which needs adequate weather protection. In small sub-stations these may be housed in a small, sheet-steel, lock-up cubicle, carried from the framework provided for the high-voltage gear if there is no actual switchgear required on the L.-T. side.

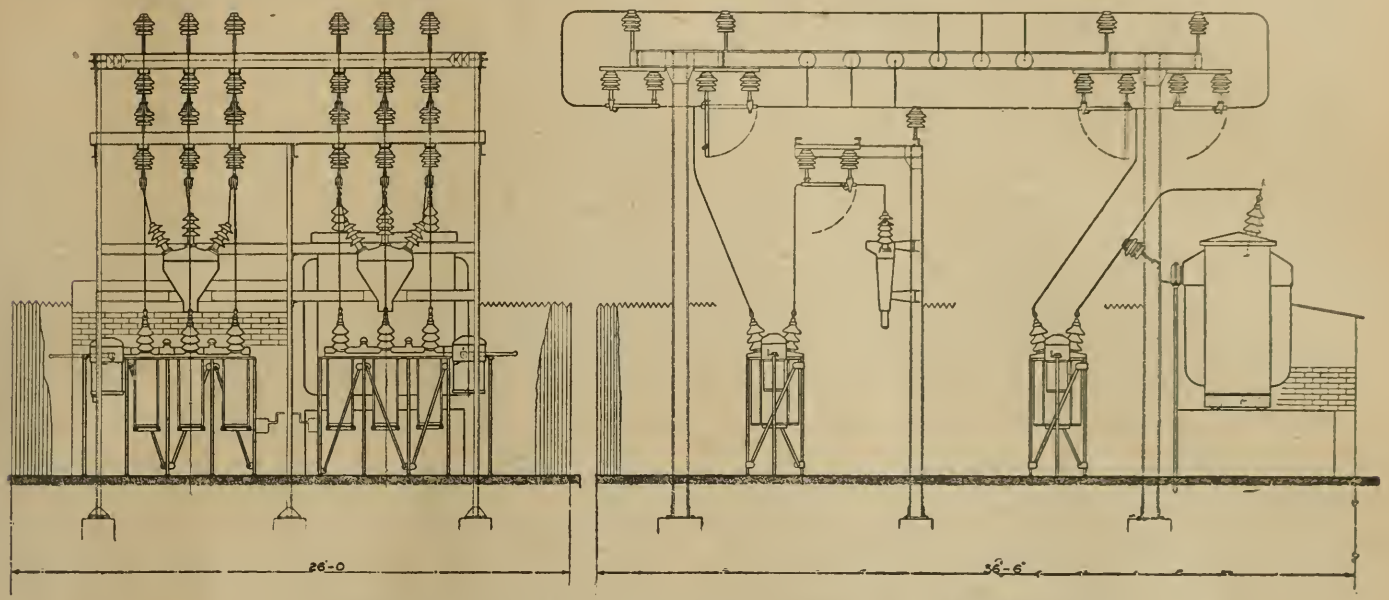

Fig. 4.—End Elevation and Section through One Feeder and Transformer Circuit.

The writer is of opinion that this voltage limitation is not insuperable, but, for the time being, we may confine our attention to those outdoor stations where the pressure is above that of generation.

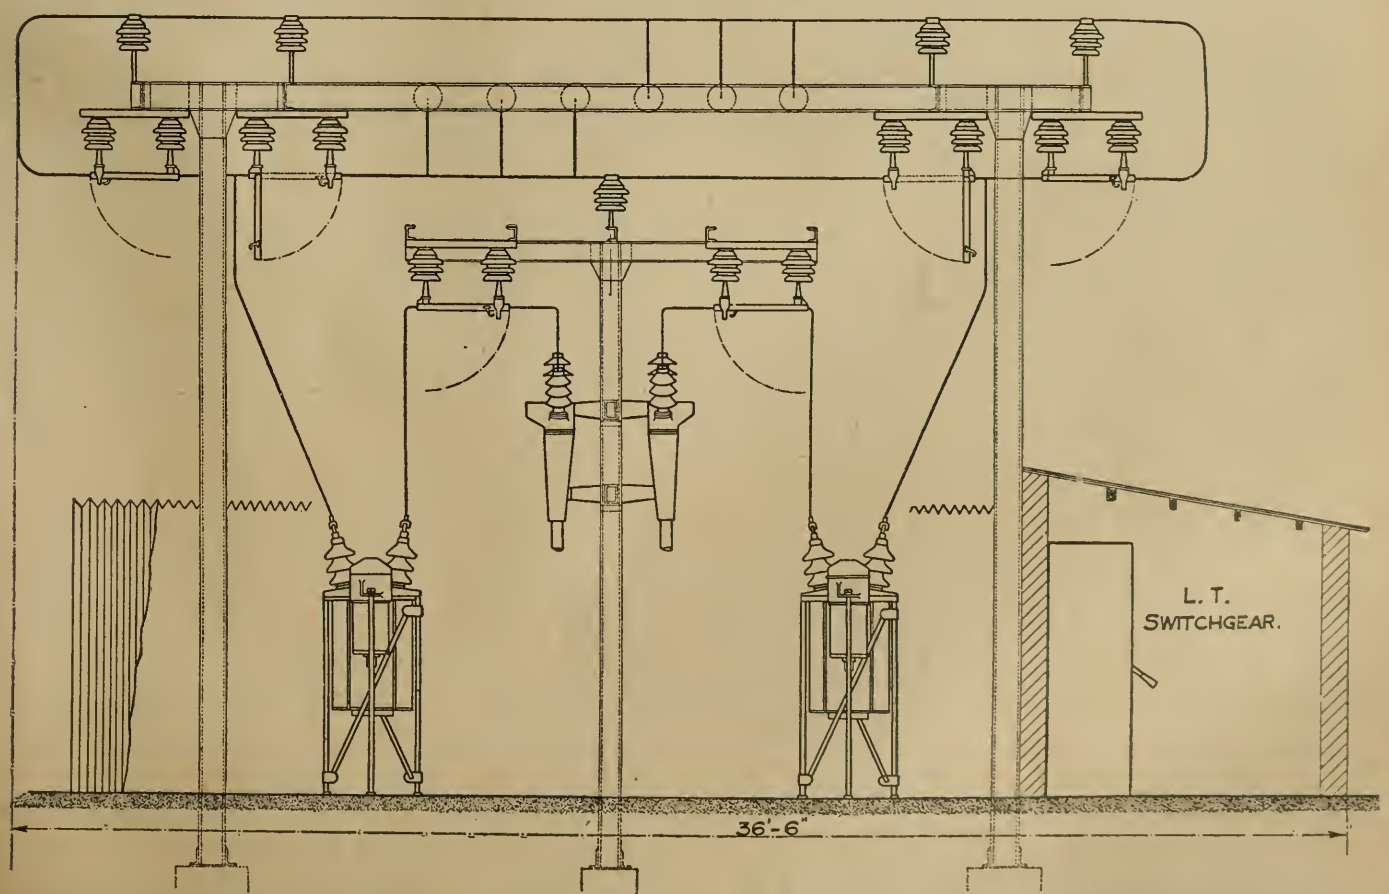

Fig. 5.—Section through Feeder Circuits and L.T. Switch-House.

Protection Against Rust.

A matter of prime importance is the means to be adopted to prevent rust on steel structures exposed to the weather. One solution is to galvanise the steel and assemble with

sherardised bolts. Unless the work be done really well, however, and no drilling or reaming of holes on site be necessary, deterioration will occur in time. Those parts adjacent to live conductors are probably best treated in this way. Ordinary paints are generally useless, because in time they dry hard and crack or flake off, particularly at the vulnerable joints.

The most satisfactory protection for surfaces readily accessible is to apply two or three coats of a paint having a bitumen or graphite base. These do not dry dead hard, but always remain flexible to a degree, permitting slight movements without injury to their surfaces.

It has been suggested that ferro-concrete should be used for supporting structures to avoid this anticipated trouble due to rust. The construction generally necessary does not lend itself to this class of work, which would be extremely heavy and costly. In fact, the design would probably end as a steel structure, encased in a concrete shell, which also would crack and admit moisture if there is any " working " under wind pressure.

To give a clear idea of the possibilities in high-voltage switchgear design two schemes are presented.

Details of a 33 kV Scheme.

In Figs. 2, 3, 4, and 5 are shown 33 kV transformer sub-stations, such as may become common requirements in this country when our super-station schemes are developed. Since in most cases (at least, at the urban terminal end) cable transmission will be essential, it has been assumed that the 33 kV line is brought underground to the sub-station.

Considering first the indoor sub-station, Figs. 2 and 3, a single three-phase O.I.S.C. transformer is housed in an isolated cubicle, which is accessible from outside the building only. Such a construction serves to limit the spread of fire, should one occur.

The L.-T. switchgear might be accommodated on the main floor, adjacent to the transformer cubicle, or if this space can be employed advantageously for stores or offices, advantage may be taken of the height of building by placing the H.-T. switchgear and control panels on top of the transformer cubicle. In an alternative arrangement the door to the transformer cubicle could open into the building, so that for repair work the transformer can be run from its cell into the main building.

The H.-T. switchgear is shown arranged entirely without cubicle work, a rolled-steel or pipe-work structure being employed to carry the selector switches. The space allowed for the operation of the selectors is unusually small, and might with advantage be increased, since it is not easy to withdraw a link from a position almost immediately below it.

In the particular case studied there were two incoming feeders and one outgoing feeder on the H.-T. side, in addition to the transformer circuit.

Floor Space.

The floor space occupied by the complete sub-station is 24 ft. by 48 ft. 6 in. (1 160 sq. ft.), and the cost of building may be put at £1 280. The cost of switchgear and transformer of indoor type erected would be approximately £3 570, giving a total cost for the indoor station of £4 850.

The corresponding outdoor arrangement is practically self-explanatory. The H.-T. circuits are arranged back to back. On one side of the structure the outdoor transformer is mounted on a concrete plinth of such height that, when necessary, the transformer can be skidded direct on to a lorry for removal. Beside this plinth is provided a small, lean-to building to house the L.-T. switchgear and control instruments. To prevent the access of unauthorised persons a corrugated-iron fence surrounds the whole structure.

In this case the ground space occupied is 36 ft. 6 in. by 26 ft. (946 sq. ft.). The cost of steel structure, concrete plinth, lean-to, concrete flooring, and fencing would be approximately £225, and the switch and transformer gear £3 900, giving a total for the outdoor scheme of £4 125—*i.e.*, an economy of 15 per cent.

(To be concluded.)

Reviews.

Thermionic Tubes in Radio Telegraphy and Telephony. By J. Scott-Taggart. (London: The Wireless Press, Ltd.) Pp. xxiii+424. 25s. net.

The volume under consideration appears to be a record of the development of the use of thermionic valves in radio telegraphy and telephony.

A short section at the beginning is devoted to a descriptive explanation of the phenomena occurring in thermionic valves and is followed by descriptions of the two electrode and three electrode valves. The use of these valves is described in following chapters as detectors, as amplifiers, as retroactive amplifiers and as high frequency and low frequency single and multistage amplifiers. Succeeding portions of the book deal with reception of continuous waves, the transmission of continuous waves, the use of valves in oscillators and wavemeters, and in wireless telephony. The two final chapters deal with the dynatron and with miscellaneous vacuum tube devices.

The author appears to have obtained much of his information from patent specifications. Much useful information can be obtained from this source both from the complete patent specifications and also from the volumes of abridgements published by the Patent Office. Though it is necessary to bear in mind that the granting of a patent does not insure its validity, nor does it imply that it will work. On p. 57 the author refers to an appendix giving a list of vacuum tube patents and original papers, unfortunately this appendix has been omitted.

It is thought that the book will be of greatest interest to the wireless amateur as it is couched in simple language and the majority of its statements and explanations are neither supported nor encumbered by any mathematical reasoning. The book is provided with circuit diagrams to an extent almost bewildering and we consider that much unnecessary repetition occurs both in the diagrams and in the text. As an example of the latter we notice that heterodyne reception is fully described on p. 252, it is again described on p. 339 in connection with wavemeter measurements, and once again on p. 348 in connection with measurement of capacity.

A defect in the book is the loose wording which frequently occurs. For example, on p. 150 we are introduced to a " step up " transformer, the resistance of whose primary winding " should be as high as possible." Resistance is not an advantage in a transformer it is an unfortunate accompaniment to a winding with a large number of turns, and statements like this have in the past inspired enthusiastic amateurs to rewind their apparatus with eureka wire. Again, on p. 244, an aperiodic anode circuit shown in Fig. 208 is described as oscillatory. Another instance, on p. 292, " It is unnecessary to have a separate aerial circuit loosely coupled to the *anode oscillatory circuit*. The reasons which necessitate this latter arrangement in an ordinary spark set do not apply."

In dealing with the methods of keying with valve transmitters Mr. Scott-Taggart falls into a common error in describing the marking and spacing wave method as " most undesirable since two wavelengths are being emitted and cause considerable interference with other stations." As a matter of fact this system will usually cause less interference than any other, since it is the only system by which undamped waves are radiated.

Costing for Manufacturers. By W. H. Hazell. (Nisbet & Company, Ltd.) 12s. 6d.

The war has given us quite a literature of costing. The Ministry of Munitions set up the most elaborate machinery for arriving at the cost of the products that it needed, and, at the same time, created a large class of costing experts, several of whom have since the war put their experiences into print, and given to the world their ideas on the science of costing. The volume now published from the pen of Mr. W. Howard Hazell, under the above title, will, therefore, be the more welcome because the author can speak on these matters with an authority greater than that of most writers. Mr. Hazell discusses very briefly the general principles underlying a true costing system, and then dives into detail. The essential features of costing are discussed one by one, and practical advice on the ascertaining, collecting, and application, of costing figures is given under appropriate headings. The matter is copiously supported with diagrams, and specimen accounts, while models for seventeen different forms appear as appendices.

Mr. Hazell fails, however, in a curious and remarkable way to understand the true purpose of the art which he is teaching. He thinks a business is carried on with the intention of charging to the customers the total cost of producing the goods, to which should be added a reasonable profit. The fact is, of course, that a business is carried on with the object of producing goods at a price which the public will readily pay. The latter definition makes a costing system far more important, and puts it on to a higher plane than Mr. Hazell appears to understand.

Protective Apparatus for Turbo-Generators.*

By J. A. KUYSER.

The author details the causes of electrical breakdowns on turbo-alternators, and discusses several well-known methods of preventing damage to the equipment when trouble occurs. He also describes a new system which aims at eliminating some of the shortcomings of existing methods. The need for, and points in the design of, automatic field switches are discussed at some length, and a means of localising fires is given.

The increase in size of distribution systems, power plants and generating units involves new problems in protection. Many improvements have been made in oil switches, automatic tripping devices and in the arrangement of protective reactances to control and limit large amounts of power. So far as the distribution system is concerned, satisfactory protection can now be obtained. Formerly it was not possible to secure the same degree of protection on turbo-generators and supply apparatus, but great advances have recently been made. Electrical breakdowns have frequently occurred on large turbo-generators where the resulting arc has ignited combustible material on the end windings; or, if in the slot portion have burnt the laminations, rendering a complete rewinding and even core rebuilding necessary, and resulting in a prolonged interruption of the supply.

Electrical Breakdowns in Alternators.

The majority of breakdowns in turbo-alternators are due to: (1) Faults between turns in the stator end-connections, or between conductors in the slot; (2) faults between phases on the stator end-connections; (3) faults to earth on the stator end-connections; (4) faults to earth in the stator slot conductors; (5) short-circuits or earths in the rotor winding..

Most serious breakdowns occur on the end-connections of turbo-stators, which are exposed to various prejudicial effects from the cooling air, even though the latter may be cleaned by wet-washing apparatus. Dirt may deposit, free moisture may be carried over due to defective action or freezing of air washers, and condensation of atmospheric moisture may also give trouble. Owing to the complicated shape of core windings the same high grade insulation as on end-connections may be impracticable, and faulty connectors cannot be eliminated by a high-flash test of 50 to 100 times operating voltage when the machine is completely wound. Earths inside slots are rare when mica wrapping has been used, but may occur on older machines and cases of deterioration or slot insulation owing to vibration have been recorded. Faults in rotor windings are usually due to broken connections, displacement of end-windings through centrifugal force, or to the use of combustible material in slots. Such faults, however, do not jeopardise the whole machine.

Precautions for preventing stator breakdowns include (1) care in design and manufacture, (2) installation of suitable air-cleaning apparatus, (3) care in operation, and (4) protective reactances. In dealing successively with these items the author emphasises the necessity of using insulation capable of withstanding the temperature met with, and the dielectric and mechanical stresses. Very few cases of breakdown due to temperature rise have been noted. Bracing the stator winding, especially the end-connectors, and efficient lamination of conductors in large machines are of great importance. Interchangeability of individual coils is sometimes specified, but this feature is of no avail unless protective gear, to localise damage, is provided.

The air-circulating system, which avoids the drawbacks of wet and dry-air filters, is mentioned with approval. The use of internal and external reactances for protective purposes greatly reduces shocks on generators, but nevertheless breakdowns occasionally occur, and in such cases the best that can be done is to isolate the machine and "kill" its field as soon as possible so as to limit the damage. Means for extinguishing fire should also be available.

Alternator Protective Devices.

Modern protective gear should operate on all possible faults in the generator or in the cables between the generators and busbars, but should be inoperative for faults and short-circuits external to the generator and cables. The gear should operate the main circuit breaker, interrupt the field current and reduce the generator voltage to a small value in the shortest time. Further, it should not introduce new weak points and so increase the risk of breakdowns.

The system most commonly used is the Merz-Price balanced protective gear, whose most serious drawback is that if a fault occurs between different turns of the same phase winding the fault currents are purely internal and will not cause unbalancing of the currents in the phase terminals. No protection is therefore obtained for such faults until they develop into an earth or into a short-circuit between phases; moreover, two current transformers seldom have identical magnetic characteristics, and perfect balance is therefore seldom obtained. A heavy magnetisation due to a short-circuit may upset the magnetic balance. This defect is evident on heavy overloads. The difficulty may be overcome by a coarse setting of the relay, but in this case the earthing resistance must have a low value. Hence with a fault to earth the fault current may not be sufficient to trip the gear.

Self-Balancing System.

The self-balancing system, proposed by Mr. J. R. Beard to overcome some of the defects in the Merz-Price system, has been adopted in several power stations. Current balance is obtained by a single transformer, thus eliminating the difficulties in obtaining a perfect balance mentioned above. But as regards faults between turns, the conditions are the same as in the Merz-Price gear.

Mid-Point Protective Gear.

A proposal (by the author and Mr. J. R. Beard) for a protective gear which will operate for all possible faults, including faults between turns, is illustrated in Fig. 1. The protected generator A, B, C, D is provided with tappings E, F, G from the mid-point of each phase. Reactance coils (or potential transformers) are connected in parallel with each phase and also provided with mid-point tappings M, N, O. The mid-point of the generator and that of the reactance coils are connected together. Current transformers are inserted in the mid-point connections and the secondaries of these transformers are connected to the relays.

When the machine is in normal operation the inter-connected points of generator and reactance are at the same potential and no

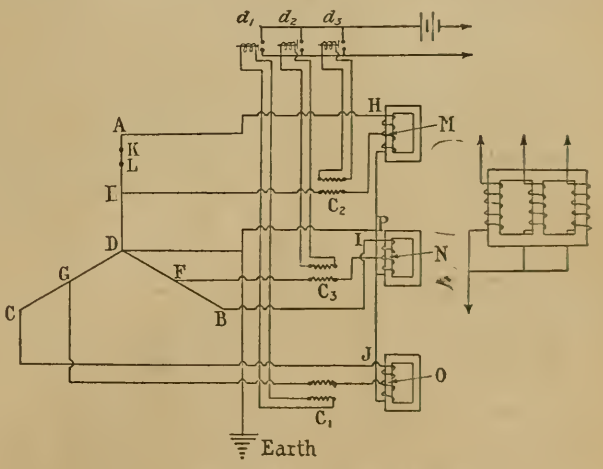

Fig. 1.—Mid-Point Protective Gear.

current will flow in the mid-point connections. If a fault occurs between turns, for example between points K and L (Fig. 1), the number of active turns between points A and E will be reduced and at the same time the flux will be weakened by the demagnetising action of the fault currents. Both actions will reduce the voltage between A and E and, to a smaller extent, the voltage in ED. The voltages in AE and DE will therefore be different, whereas the voltage of HM and NP will remain equal, being generated by the same flux. A current will therefore flow in the mid-point connection EM. The voltage and current induced in the mid-point connection is used to operate a tripping relay (by means of a transformer).

The unbalancing of the voltages in the phase halves or the shifting of the mid-point in the generator phase winding occurs not only on a fault between turns, but also when a fault occurs to earth or between phases.

The system will therefore deal with any fault in the generator winding, including faults between turns, and will give more complete protection than has hitherto been obtainable. A fault outside the generator, for instance, in the cables leading from the generator, will not cause unbalancing, and the generator leads would therefore not be protected. To include the leads in the protection, the cables can be provided with a conducting shield surrounding the central core and insulated for half the phase voltage from the core and from the armour. This shield is connected to the mid-point at the generator end. The reactance coils in this case are located at the switchboard and their mid-points connected to the shield. A fault from one of the cores to earth must be preceded by a fault from the

* Abstract of a Paper read before the Institution of Electrical Engineers.

core to the shield which forms the mid-point connection, and such a fault will operate the gear.

A Simplified Arrangement.

A simplification of the arrangement can be made in the case of a generator where the phases are wound in two parallel circuits. In this case the mid-points of the two parallel windings can be interconnected over the transformer which operates the relay. This system is, however, very limited in its application, as few generators are wound in two parallel circuits.

Automatic Field Switches.

As previously mentioned, a complete generator protective equipment should include an automatic field switch to interrupt the field circuit immediately the fault occurs. The automatic field switch may be located in different parts of the field circuit and may take the form of (1) a switch in the exciter field circuit, (2) a reversing switch in the exciter field circuit, (3) a circuit breaker in the main field circuit, (4) a switch to short-circuit the slip-rings and exciter.

Hitherto, in order to limit the voltage-rise on breaking the induction circuit, it has been standard practice to provide a non-inductive field-discharge resistance or " kicking coil " where a field circuit was to be opened. The normal operation of the field-discharge switch is to connect the field winding in parallel with the discharge resistance and subsequently to open the current supply from the exciter armature. Thus after the switching operation the field circuit is not interrupted, but the current circulating through the winding and the resistance is allowed to die out gradually. The ohmic value of the discharge resistance is, as a rule, roughly equal to the field resistance.

Time Required for Field Discharge.

An appreciable time elapses before the field current decreases to a reasonable value ; thus in the case of a 8 900 kVA 2-pole machine a current of 10 per cent. of no load value is attained in 11 secs. For a 23 500 kVA machine the time might be 30 secs. or even 1 min.

It is evidently necessary in the case of a stator breakdown that the voltage shall disappear as quickly as possible. The present arrangements appear unsatisfactory. The discharge is too slow and the voltage is maintained for a sufficient period to cause appreciable damage. The first remedy is to use a high discharge resistance, as the discharge time is inversely proportional to the total resistance in the discharge circuit. But the use of such high discharge resistances may lead to a high voltage-rise on the rotor winding during the switching If, as is usual, the discharge resistance is equal to the field resistance, the voltage-rise is equal to the excitation voltage, but if a high discharge resistance of, say, 19 times the field resistance is used, the voltage-rise would be theoretically 19 times the excitation voltage.

Influence of Damping Currents in Rotor Body.

The next factor to consider is the damping action of the closed circuits formed by the rotor slot-wedges and the rotor body. The effect of such currents is to reduce the high voltage-rise if a high discharge resistance is used, but to retain the sluggishness of the discharge. The damping circuit may be represented by a separate field winding short-circuited on itself, having the same number of turns as the field winding and lying in the same slots. If the resistance of the main field is equal to R_f, the ohmic value of the discharge resistance to R_r, and the equivalent resistance of the damping circuit to R_d, the equivalent resistance of the two circuits combined will fulfil the conditions

$$\frac{1}{R_e} = \frac{1}{R_f + R_r} + \frac{1}{R_d}$$

The equivalent resistance R_e determines the discharge current and voltage. R_d can be determined experimentally by making two discharges for different values of R_r and recording the current/time or voltage/time curves.

In a case where $R_r = 30\ R_f$ a damping effect equivalent to a discharge resistance of 38 times rotor resistance was recorded. An observed voltage rise of 25 times the excitation voltage on opening rotor circuit was recorded. This is less than the value derived from consideration of time-constants because the circuit was not opened absolutely simultaneously. The discharge resistance which has hitherto been used in conjunction with automatic field switches is therefore unnecessary, there being no danger of an insulation breakdown if the main field is opened by means of an ordinary circuit breaker. The elimination of the discharge resistance will greatly increase the value of the protection obtained, save the unnecessary expense of resistance units and special switches, and reduce the number of moving parts, thus increasing the reliability of the switch.

In the previous considerations the field switch has been assumed to be located in the main field circuit. Another method is to provide a small automatic switch in the exciter field circuit.

Switch in Exciter Field. A Suicide Connection.

A third method is to use a reversing field switch in the exciter field so that the field circuit is opened and subsequently reversed. The reversal of the field has the advantage that the remanence of the exciter is destroyed, and the remanent voltage on the a.c. terminals reduced. The discharge time depends only upon the total resistance in the discharge path, and in this respect there is no advantage over the simple exciter field switch.

An advantage could be obtained from the use of a reversing switch, by exciting the exciter field coils separately from an independent source and allowing the exciter to generate reversed voltage.

The main field switch produces a more rapid reduction of the current during the first period of the discharge, whereas the separately-excited reversed exciter would give a more rapid reduction for the final part of the discharge.

Slip-Ring Short-Circuiting Switch.

A fourth method of interrupting the field current is to establish a dead short-circuit between the two slip-rings. This will short-circuit the exciter armature, and some (though not excessive) sparking will therefore occur on the exciter commutator unless a preventive resistance is used. The method is quite practicable. The disadvantage lies in the fact that the resistance in the discharge path is smaller than in any other method, and the discharge time is correspondingly lengthened.

Method of Tripping Auto-Field Switch.

The field switch can be tripped in different ways, viz., (1) direct from the fault-current relays, (2) by means of an auxiliary switch on the main a.c. circuit breaker, (3) by means of a combination of methods (1) and (2), (4) a time-lag may be introduced after the tripping of the main switch.

If all apparatus in the protective system could be depended upon, that method (1) would doubtless be preferable, on account of the more rapid action. It happens sometimes, however, that the relays operate for a fault outside the generator ; or reverse-power relays may operate for a failure in the motive power. The field switch would then be tripped and, if the main breaker failed to operate due to a defect in the tripping mechanism, the sound machine will remain connected to the system with the field out of circuit. Even so, nothing serious usually happens if the field circuit of one of several parallel-running alternators is interrupted for a short time.

The next possibility is that in the case of faults occurring in the machine the main a.c. breaker fails to open. If the field is not interrupted the system will feed into the fault, as will also the defective generator itself. If the field is interrupted the faulty machine will not contribute to the fault currents. The energy flowing into the fault, and the damage, will therefore be appreciably reduced, particularly if the faulty machine is large compared with the other plant in parallel to it.

The object of method (4) is to prevent large voltages being induced in the rotor due to the inductive effect of the fault currents in the stator. For the same reason it has also been proposed to connect over-tension devices between the rotor slip-rings. Experiments carried out by the author on a machine with a solid rotor have shown that the voltages induced in the rotor in the case of a stator fault are of even smaller magnitude than those observed for a direct opening of the main field circuit under no-load conditions, and are therefore not of a dangerous nature.

The conclusion is, therefore, that operation directly from the fault-current relays is the most satisfactory method, although there would not be much to choose between methods (1), (2) or (3) if the main breaker is very quick-acting and is periodically tested to eliminate all possibility of " sticking."

Extinguishing of Fire.

Although the installation of electrical protective devices greatly reduces the possibility of fire in the windings, it is still advisable to provide means for extinguishing a fire in the extreme case of the protective gear failing and the winding becoming ignited. The usual method of extinguishing is to apply a hose or a fire extinguisher through the inspection covers in the stator end guards. This is a very drastic method and should be used only as a last resort ; also there is usually so long a delay in applying the extinguisher that the winding is ruined. If serious damage is to be prevented, extinguishing must be done *immediately* after the accident and preferably automatically by the action of the fault-current relays, and an extinguisher must be used which will not ruin the insulation. It is sound practice to provide air dampers in the air inlet and outlet, which are automatically closed by means of solenoids energised from the protective relays.

Another advantage of dampers in the air ducts is that the air circulation can be positively stopped while the generator is not in operation, thus preventing a condensation of humidity due to the natural draught in the building. Such condensation may also take place when a cold machine is started up and the air temperature is above the temperature of the machine. When this condition occurs it is therefore advisable not to open the dampers before starting up, but to leave the dampers closed until the generator has attained a temperature above that of the cooling air.

The Institution of Electrical Engineers.

At the meeting of the Institution of Electrical Engineers on Thursday, April 27, a Paper on "Protective Apparatus for Turbo-Generators" was read by Mr. J. A. Kuyser. An abstract of the Paper will be found on another page of this issue. We give below an account of the discussions which took place in London, Manchester and Newcastle.

DISCUSSION IN LONDON.

The PRESIDENT, in opening the discussion, said the Paper raised a subject of great interest. He was inclined to think that when they had Papers on protective gear it would be a useful thing to be given some idea of the cost of the gear, but far more important than that was an idea of the value of the property that the gear was to protect. In ordinary electrical installation work there must be many thousands of pounds' worth of gear put in to provide against faults that happened, he would not say once in a century, but once in a great many years. The protective gear described in the present Paper was not of that class; it was a gear providing protection against an enormous amount of possible damage that could be valued at thousands and thousands of pounds, and those who had to run big turbine plants knew the great amount of damage, loss, and annoyance that was caused because there was no really effective protective gear.

A Designer Unsympathetic.

Dr. S. PARKER SMITH said he had not very much sympathy with the Paper on general lines. He could sympathise with the station engineer who desired to protect his machinery against damage, but from the designer's point of view they should be a little more critical of their own work. They ought to be able to design turbo-alternators—in fact, he was sure it could be done—so that protection against external faults was unnecessary. It ought to be possible to have a short across the terminals without injuring the machine. If the machine would not stand that, then we had not reached perfection. This involved the question of how much we were prepared to pay for reliability. A good deal could be done to prevent the destruction of machines by paying greater attention to mechanical details. The bracing of the overhang, for instance, was now done very much better than it used to be. He mentioned this question of mechanical design because he had not very much faith in the idea of breaking the field rapidly. The effect of cutting off the field current was not to destroy the field, but it was the existence of the field that was going to cause the damage once the short circuit started. When they broke the field circuit the flux might continue for a considerable time; and it would be interesting to know how long the flux did persist inside the alternator. He felt it was wrong to rely on cutting off the field current as sufficient protection until we had more evidence of the time taken by the flux to die away.

Breaking by Relays.

Major K. EDGCUMBE said he was pleased to notice that the author strongly recommended the breaking of the field by the relays instead of by circuit breakers. His own feeling was that it was better to chance the remote possibility of having the machine left on the bars without its field, than to have the certainty that they were wasting valuable fractions of a second before they started breaking the field. The author seemed throughout to have assumed that he had done his job when he had reduced the voltage to zero, but that was not really so.

A Candid Admission.

Mr. H. W. CLOTHIER said the significant general feature of the Paper was the candid admission on the part of an alternator building expert that automatic protection could not be put on one side as an unwarranted appendage, and the user who was content to ignore the study of these automatic protective devices on the plea that they were more bother than they were worth was, to say the least, taking unnecessary risks. The author brought the weight of his experience to bear on three features: (1) The fault between turns; (2) the earth fault near to the neutral end; and (3) the extent to which an alternator would damage itself after the oil switch had isolated it unless the alternator field was suppressed. As regards the fault between the turns, hitherto with the balanced systems of protection we had been satisfied to allow such faults to develop to leakage faults to earth. This they must do, and thereby they disclosed their locality, and could be isolated without incurring much injury to the machine. As to the earth faults near to the neutral end, these might be so reduced in current by the neutral resistances that they were insufficient to operate the relays until they developed to faults between phases. Much depended upon the permissible setting of the relay and the amount of resistance inserted in the neutral. The proper way to shorten the unprotected part of the alternator winding was to use a larger neutral resistance, and so increase the amount of current which it would allow to pass. It was a mistaken practice for these to be installed to pass less than full load current; twice full load current would be better in most cases. With regard to the suppression of the field circuit, exciter field switches had been made to operate simultaneously with the Merz-Price balance protection for some years, but latterly it had been shown to be advantageous to operate by means of a circuit breaker in the main field. He submitted that no serious case had been proved against the fifteen-year-old Merz-Price balanced system or the five-year-old self-balanced system, but he agreed with the author that the mid-point or between turns system should be given a trial. The objections to the system were the introduction of the potential element in the protective gear transformers; the extra tapping on the stator coils; and the absence of protection for the alternator terminals. All these, however, could be overcome by careful design of the detail parts. The insulation of the transformers must be made very sound and with a much higher margin for safety than was usually allowed on potential transformer designs. He was assured by two alternator makers that there was no difficulty in finding a suitable place for the tapping on the alternator winding or for taking a well insulated conductor away from this place to a terminal. The author's proposal to screen the terminals and cable by a mid-point connection to the switchboard depended mainly for its success on a good design of terminal box mounted on the alternator frame which would combine high tension and mid-point screen conductors, preferably compound filled. An alternative method would be to use, in addition to the mid-point protection system, a balanced leakage protection. He felt it was most important on all such protective systems that there should be an ample margin in the sensitiveness of the relays between the test room results and that promised or put into use in actual practice. Just as we had a factor of safety in the strength of a structure, so should we have it in reliability of operation, and it was for this reason that he specially urged that the earth current should not be cut too fine for the sake of saving £100 or so on the cost of the earthing resistance.

Temporary Expedients.

Mr. A. D. SLOAN said that as a designer he was inclined to agree with Dr. Smith's remarks, but at the same time it had reluctantly to be admitted that breakdowns did occur, and that we were not absolutely immune. He understood the author's apparatus had only been tried in the factory, and he would like to know if it was sufficiently quick acting to isolate the machine and kill the field before the incipient fault developed into a fault. If it did not do that it was no use, and they might just as well rely on the Merz-Price gear. Endeavours must be made to secure sufficient reliability in the machines themselves to obviate the use of protective gear altogether.

Necessity for Simplicity.

Mr. H. BRAZIL said that what staggered him in connection with the author's new system of protection was the number of potential transformers which had to be used, things which we were always endeavouring to get away from. That was a very grave objection.

The Operating Engineer's View.

Mr. L. M. JOCKEL, speaking from the operating engineer's point of view, said the author's new system was exceedingly ingenious and was worthy of further research. At present it seemed to be exceedingly complicated, and would add considerably to the capital expense of the alternators in the case of very large machines. Moreover, he doubted whether many operating engineers would care to tackle the system until it had been further tested in practice. His own experience of faults between turns was that they were never evident, and they usually became a fault between phases or a fault to earth. It was, however, refreshing to have a Paper of this nature from an alternator builder. He did not think many operating engineers would tolerate the second arrangement suggested by the author. It seemed to be totally bad from the reliability point of view, and it had several theoretical disadvantages. Moreover, his experience had been that the less potential gear they had in a power station the safer they felt.

Mr. L. ANDREWS recalled that when he read a Paper before the Institution twenty-five years ago on protective devices for a.c. apparatus the topic of the criticism, particularly from the generator makers, was that the devices were very pretty, but if only generators were designed properly they would not be needed. That still seemed to be the criticism now, after that period of twenty-five years. What was wanted was generator makers and switchgear makers to work in parallel with the object of tackling this question, and it was gratifying to see a Paper from a designer treating the whole problem of the generator and the switchgear as one engineering proposition.

More Bother than Worth.

Mr. E. T. WILLIAMS said his experience was that in the majority of cases the troubles involved with the protective devices were

greater than those they were put in to protect. As had already been stated, what was wanted was greater simplicity because that would of necessity bring with it greater reliability, and if the advice of Dr. Parker Smith was followed by designers, and more attention given to the machines and less to the protective devices, we should be on the right lines.

DISCUSSION AT MANCHESTER.

Mr. J. A. Kuyser's Paper evoked a provocative discussion before the North-Western Centre on April 4. In general it was agreed that the Merz-Price system had proved its efficiency in spite of some disadvantages, although power engineers were inclined to be sceptical of protective systems. Those essential auxiliaries, potential and current transformers, were severely castigated and equally as warmly defended.

Improvements in Merz-Price Gear.

Mr. G. A. Cheetham said that Merz-Price gear could now be set to give 15 per cent. of full load without any danger of tripping under overload conditions. Increase in impedence of relay circuits had enabled current transformers to be worked higher up the magnetisation curve, balance then being more readily obtainable. The self-balance gear gave a definite current setting instead of a percentage of the full load current, as the lowest fault current operating the relays was the minimum fixed current which would flow through a bar primary transformer to provide voltage enough to overcome the relay impedance. Under normal conditions self-balancing gear gave lower fault setting than the Merz-Price gear, but an improved scheme recently introduced enabled designers to give Merz-Price gear protection at 7·5 per cent. instead of 15 per cent. with an earthing resistance passing full load current with a dead earth on one phase. The new mid-point protective gear gave protection between turns, but it needed potential transformers, and the generator terminals themselves were not protected.

A Power Engineer's Abhorrence.

Mr. H. C. Lamb said that the power engineer abhorred interruption of supply through automatic gear functioning without cause, and hence he fought shy of protective devices, automatically operated dampers and steam connections. The author had omitted mechanical faults on rotors as a possible cause of damage to high-tension windings. The closed air system had great advantages. The pressure of water in the cooler should be below that of the atmosphere. The system of mid-point protection had something to recommend it, but came rather late in the day, as in these days there should not be any faults between turns, even in end windings. In the author's scheme of connecting potential transformers a breakdown of the winding of one of the transformers or the blowing of one of the protective fuses would cause the relay to operate and cut out the generator. In the scheme for protecting two alternators in parallel two generators would be cut out, one a sound machine, because of a fault on one. The aim should be to kill the field instantaneously.

Mr. G. A. Juhlin said that very small faults frequently caused complete burn-outs due to fire, which would have been avoided had a system of protection been available. The author's remarks regarding the use of string for bracing end connections could not be endorsed. The system of mid-point protection was applicable to transformers needing protection between turns as well as machines.

Protection for Protective Gear!

Mr. H. A. Ratcliff criticised the minimum operating current taken by protective systems, due to the defective design of transformers and relays, and the erratic character of reverse power relays. The weak point of the mid-point system was the potential transformer. Since protective gear had to protect plant it had to be more reliable than the plant to be protected, and this was unlikely.

Mr. D. S. Paxton referred to an air-cleaning apparatus intermediate between the wet and dry filters, consisting of thin copper-plated steel tubes, the surface of which is covered by the cleaning medium, a high-flash, highly viscous oil.

Mr. S. Ferguson suggested that some generator breakdowns originated in surges on the cable system outside the generator itself, causing failure between end turns. This could be prevented by external reactance. The author had not mentioned the Ferranti field protection system, consisting of a core-balanced transformer slipped over the lead cover of the cable. He advocated the elimination of all relays and operating direct with the fault current. The mid-point system was too complicated to be of value, especially as a fault between turns would soon go to earth.

Potential and Current Transformers.

Mr. J. Frith referred to and underlined the criticism expressed about potential and current transformers. They were flimsy and were not engineering devices. He suggested eliminating oxygen from the closed air cooling system and using nitrogen or carbon dioxide to prevent fire spreading in the machine.

Mr. R. Townend asked for a definition of the term "quickly," if the field was to be killed. Was it ten seconds or sixty seconds? Short-circuiting the terminals after opening the main field circuit was the quickest way of killing the voltage practically instantaneously. Regarding short circuits between turns, voltages might be piled up between turns, especially end turns.

Mr. E. P. Hill gave some examples from practical experience of breakdowns and said that it was possible, in the author's mid-point system, to get two faults on even distance from the centre taps.

Mr. J. H. Buchanan defended the makers of potential and current transformers, especially in view of the difficulties created by slight increases in cost. Specifications varied so much that it was impossible to supply all varieties, and standardisation was thereby discouraged. It was true that potential transformers, which had more turns, were less dependable than current transformers, but great improvements had been made. Finally, the best results were obtained by not using the transformer for both protective gear and instruments.

DISCUSSION AT NEWCASTLE.

Mr. Kuyser's Paper was read and discussed in Newcastle on March 27. We give below a summary of the various speakers' remarks:

Mr. C. H. Davidson considered that a neutral switch should be provided as if this neutral switch could be opened sufficiently rapidly all damage to the generator would be prevented. If the generator air ducts were entirely within the station no trouble should be encountered due to condensation of moisture. With reference to the mid-point protective gear which was so arranged that it would trip out two machines when it operated, although one machine would be healthy, and as the author said, ready for synchronising again, how was it possible to ascertain which machine was all right and which was faulty? The arrangement of the slip-ring short-circuiting switch was open to objection, as the exciters were not usually so robust as the alternators and damage was more liable to result. It was necessary to kill the alternator field as quickly as possible and to do away with all damping circuits, but it was not desirable to break down the exciter insulation every time the field switch was opened.

An Unusual Procedure.

Mr. H. W. Clothier made the unusual statement that he had read the Paper—a proceeding apparently not followed by all the other speakers. He considered that the people responsible for the protection of alternators had not previously properly appreciated the necessity for such protection. The balanced systems of protection had been in use for some twelve to fifteen years, but it was only recently that generator manufacturers had realised the extent of the damage which could result to the machine through breakdowns and were beginning to pay more attention to the systems of protection which had been available so long, but had not received due consideration.

Temperature Rise and Damage.

Mr. J. Rosen did not agree that excessive temperature rise in the generators had little effect on the insulation. He considered that excessive temperature rises had caused a large number of breakdowns and was satisfied that the higher the temperature rises encountered, the shorter was the life of the alternator.

Mr. G. L. Porter said the "between-turns" protection was a great improvement on previous generator protective schemes, as the generator was really the only class of apparatus which was liable to breakdown between turns. A breakdown on the machine terminals could be taken care of by means of a screen connected to the mid-point of the gear, which was preferable to the installation of a separate protective system for this purpose. He considered it preferable to put the reactance coil at the generator terminals rather than at the switchgear terminals, as it was not usually possible to get the switchgear close to the generator, and the inductive drop on the cables would often cause a greater potential difference than that at which the gear would operate. The practice of interlocking the main and field switches was sound as, if the main switch did stick, the opening of the field switch would not matter as the damage to the generator would be done in any case.

A Complicated Arrangement.

Mr. J. W. J. Townley also objected to the author's statement that temperature rise did not appreciably affect breakdowns, as this was contrary to his experience. Operating engineers did not have much experience of generator breakdowns, but other machines were seen more often and indicate that the breakdown was frequently due to temperature rise. The breakdown of large generators was much more serious than the cost of repair would suggest. The suggestion of the combination of mid-point protection with ordinary Merz-Price protective gear would give a very complicated arrangement, in which the possibility of a wrong connection causing shut-down would be appreciably increased. Breakdowns were occasionally caused by the protective gear, particularly if proper attention was not available. In small stations, the operating staff might not properly understand the protective gear, and its treatment would suffer accordingly.

Physics and Engineering Science.

On Wednesday, April 26, the first of a series of lectures on "Physics in Industry," entitled "Physics and Engineering Science," was delivered by Prof. A. Barr, before the Institute of Physics. The Right Hon. H. A. L. Fisher (Minister for Education) presided.

In the course of some opening remarks the MINISTER for EDUCATION said that the Institute of Physics had been founded to draw the attention of the public to the importance of physical science as a factor in industrial progress. Appeal had first been made to the business man, but the call had also been addressed to schools and colleges and to the Board of Education. He was very glad that the Board of Education should be officially associated with the admirable purpose which the Institute of Physics was designed to perform. The industrial progress of the country was insecure unless it was based on a wide knowledge of science. We had built up our industrial position in the eighteenth century by the method of trial and error. We had been very fortunate in having cheap coal and cheap labour, and being first in the field with few competitors. Thus we had been able to travel fast and far with but a very slender equipment of scientific principle. But the world had greatly changed now. In every quarter we met with competitors; the old rough and ready methods of business no longer served. Cheap labour and cheap coal had gone; science and science alone could enable us to maintain and extend our industrial progress. A large proportion of our research associations were employing men trained as physicists or physical chemists; this was a welcome sign.

An Inexhaustible Subject.

Prof. BARR said his subject was one which could never be exhausted, but the exposition of the position in regard to one industry might throw almost as much light on the possibilities in another industry as a special treatment of the conditions of that industry would provide. The professor of applied science stood in relation to the physicist on the one hand and the practitioner of the arts on the other in the position of a go-between. He ought to know what were the points of contact and divergency between their fields of activity, to be able to appreciate the standpoints from which they respectively viewed any question bearing upon their intercourse and assist in constructing the lines of inter-communication.

The Relation of Theory and Practice.

There should be little need to-day to re-open the old discussion on the relative value of theory and practice in the arts of construction and production. The question of the relative values of the knowledge gained in the study of pure science and of that gained through long experience in the practice of a particular art could not be discussed in general terms, but we should arrive at no just views regarding the application of physics in industry unless we assigned full values to the mental equipment that might be derived from each of those scources. It appeared to him that in general the practitioner in the arts had sounder views regarding the aims of the men of science than the pure physicists had of the conditions under which industrial processes could be conducted and the limitations which those conditions imposed on men who would gladly avail themselves, as far as possible, of every advance made in the knowledge of the physical principles that underlay the arts they practised.

No Place for Engineering Science.

Coming more closely to his subject, the lecturer said that there had been physicists who held that there was no place for engineering science as a special and a distinct subject in any educational system, and that the study of mathematics and physics as branches of pure science, afforded sufficient systematic training for men preparing for the engineering profession; but there had been engineering chairs in our universities for more than sixty years, and their existence had been justified. The teaching offered by the engineering faculty in a university, was not purely, nor indeed mostly technical in the proper sense of the term; it was not so much so as in a medical school, which supplied the student with a training in the practice of his profession as well as in the science on which it was founded. The term, engineering science, might be usefully taken as embracing all the systematised knowledge that formed the special mental equipment of the engineer in practice from whatever source that knowledge had been derived; and if physics was taken to embrace all that was known of the properties of matter, and the transformation of energy, of course, engineering science, in any sense of the term, must be a branch of physics.

The problems with which the engineer had to deal were in their essence, almost infinitely more complex than those that the physical investigator set for himself. The more we studied the mechanical structure of plants and animals, the more we realised how complex were the functions to be performed, and the conditions to be complied with by each and every part; but if the investigation of the structure of an animal or plant, as bearing upon its functions, involved a complex and difficult problem, how much more difficult would it be to solve the reverse problem of devising the structure that would best meet the requirements in respect of all the functions that had to be performed.

AMATEUR "WIRELESS."

To the Editor of THE ELECTRICIAN.

SIR,—I have noted with considerable interest various articles on the subject of Wireless Telegraphy and Telephony from the amateur's and experimenter's point of view recently published in the weekly journals, and can from a long experience dating back to Mr. Marconi's early experiments, concur with you in lamenting the irksome restrictions placed upon earnest research by British enthusiasts.

One hopes, however, that as a result of your publicity, coupled with the efforts of the Wireless Society of London, a greater latitude may be granted to those who, like myself, have matters wireless very much at heart.—I am, &c.

London, W., May 1. C. J. CLOSE.

Southend's Diesel Sets.

Mr. Robert Birkett, engineer and manager of the SOUTHEND LIGHT RAILWAYS AND ELECTRICITY DEPARTMENTS has long been of opinion that the salvation of the electricity department lies in the gradual substitution of Diesel engines for the old steam plant, which has always worked under difficult conditions owing to the high cost, and the unsatisfactory character of the Southend water, and, in recent years, also owing to the high cost of coal and coal carriage. The two 1 200 H.P. Diesel sets at Leigh saved the situation during the last coal strike, when the supply would have come to a standstill if they had not been available. Five Diesel sets ordered by the Corporation from Belliss and Morcom were disposed of at the request of the Local Government Board for war purposes, and in consequence of the difficulty of obtaining quick delivery of land type Diesels (with which, by the way, Mr. Birkett believes he could generate as cheaply as it could be done in the projected super-stations, having regard to capital and all other charges), the Corporation bought four 1 200 H.P. and two 600 H.P. Diesels, which were taken out of surrendered German submarines, and these are being used with their original generators, four A.E.G. and two Siemens-Schuckert. Two Heenan and Froude water coolers have been installed at each of the Diesel stations.

Visit to the Stations.

On Thursday of last week the Councillors and the Press inspected the six Diesels, of which two are at the main depot in London Road, two at Leigh, and two at Thorpe Bay, and also the battery and booster sub-station at Chalkwell Park. The first of the Diesels was put on load at the Leigh station on December 21, 1920, and by the time of last week's inspection it was expected that all the six engines would be ready for regular work. Mr. Birkett, however, admitted that one of the pair at the main depot still requires further adjustment, which is expected to be accomplished in the very near future. The working of the other five engines has been quite satisfactory. The six sets, which have been converted and installed by Belliss and Morcom, are now actually rated down to a total of 4 000 B.H.P. or 2 500 kW.

The Corporation at "Supper."

At a supper held after the opening ceremony, Mr. RADFORD, Chairman of the Electricity Committee, gave some figures with regard to coal consumption. He said the consumption at Southend was 3·9 lb. per unit, or only about ½ lb. more than at Brighton, where they had up-to-date turbine plant, but as he did not say whether the units generated by the Diesel sets were included in the calculation, the figures are not of much value as an indication of the comparative efficiency of the steam plant.

Mr. BIRKETT, in replying to the toast of his health, said the consumption per head of population at Southend was about the same as in Brighton and Blackpool—40 units per head—and the average price per unit at Southend was 4·24d. compared with 5·38d. at Brighton in 1921, and, according to the "Electrical Times" figures, about half the undertakings in the country charged more than was charged at Southend, and most of these places were in the north where coal was easier to get.

Electric Clocks.

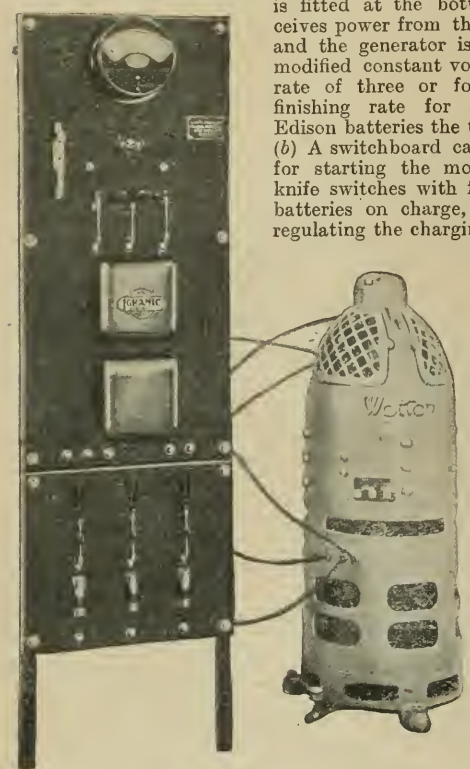
The Liverpool Overhead Railway have placed an order with GENT & COMPANY for a system of their pulsynetic electric clocks. Waterproof impulse clocks in cast-iron cases are being fitted at every station on the system, also in signal cabins, power stations, and administration departments, and all are controlled from a master clock or "transmitter" fixed at Dingle Station.

The installation is of more than ordinary interest, on account of the connecting wires which loop up the clocks being "broken" when the drawbridge at Clarence Dock swings. The timekeeping of the whole system is not affected, however, by the temporary disconnection. Further, the vibration of the steel structure, caused by passing trains, does not affect the timekeeping of the impulse clocks.

Automatic Battery-Charging Plant.

The efficient handling of materials and the uninterrupted operation of the transportation system in every industry where the storage battery, truck, tractor, or locomotive can be used, has always been the keynote in the design and construction of the various types of Wotton Battery Charging Plants manufactured by the Igranic Electric Company. Each type has been designed to meet the battery-charging requirements in connection with some one transportation problem, and they all embody perfections and refinements that are the result of many years' practical experience.

The Wotton vertical motor generator, which we illustrate, is associated with an automatic switchboard having equipment for distributing the charging current to one, two, or three batteries at once. It comprises :—(*a*) The Wotton motor-generator, consisting of an a.c. motor, mounted in the lower half of the frame, driving (through a one-piece shaft) the d.c. generator mounted above it. An annular self-aligning bearing with centrifugal pump oil circulation is provided at the top, while a combined thrust and annular bearing with splash lubrication is fitted at the bottom. The motor receives power from the line at full voltage, and the generator is wound to deliver a modified constant voltage, with a starting rate of three or four times the normal finishing rate for lead batteries. For Edison batteries the taper is not so steep ; (*b*) A switchboard carrying a knife switch for starting the motor, three single-pole knife switches with fuses for placing the batteries on charge, a field rheostat for regulating the charging rate, an automatic cut-off and reclosing circuit breaker and a combined voltmeter and ammeter.



A Wotton Vertical Motor Generator.

Twin Unit Plants.

Many factories are entirely dependent upon the industrial truck for all transportation of material and prefer to divide the charging equipment into two or more sections so that no combination of circumstances can reasonably put the trucks out of commission. Twin unit sets are manufactured to meet this demand. They are adapted to charge two batteries simultaneously at normal rate, or one battery at double normal rate, and at the same time provide a factor of safety against breakdown.

This arrangement includes two switchboards bolted together and two vertical generators. A double-pole switch, for paralleling the generators when boosting one battery, is carried on one of the panels. It is, of course, a simple matter to extend such an installation to charge any desired number of trucks simultaneously.

Assuming that two batteries are to be charged simultaneously, both motor generators are started by closing the motor switches and both charging switches are closed. The plant can then be left unattended. As soon as one battery is charged, two contacts close in the meter which is connected in the battery circuit, thus disconnecting the battery and causing the motor generator to stop. The second set is shut down in a similar manner when its battery is fully charged.

If, during the charging operations, there is a temporary failure of line voltage the set is automatically stopped and the charging circuit is opened. Immediately the supply is resumed the motor generators are automatically re-started and charging continues.

I.E.E. : North Midland Centre.

The Annual Meeting of the North Midland Centre of the Institution of Electrical Engineers was held at Leeds last week, about fifty members being present. In the absence of Mr. W. E. Burnand, Mr. W. B. Woodhouse took the chair, and the accounts were duly passed. The following officers have been elected for the ensuing year :—Chairman : Mr. W. B. Woodhouse ; Vice-Chairmen : Major H. Bell, Major E. A. Barker, Messrs W. Howard Brown, and S. Derwen Jones ; Hon. Secretary : J. D. Bailie ; Committee : T. Roles, T. B. Johnson, A. F. Carter.

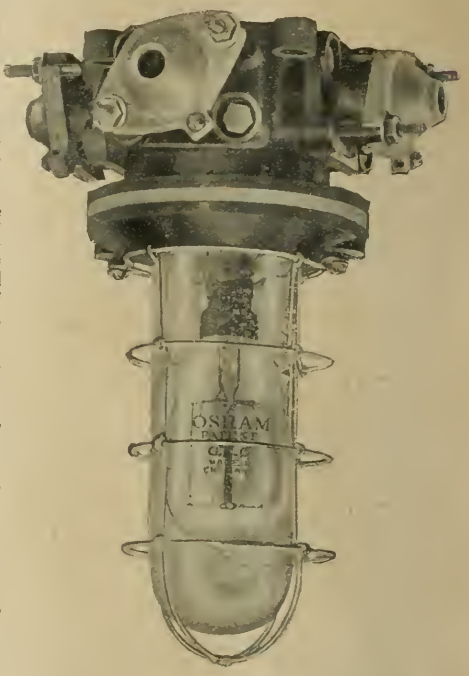
The summer meeting is to be revived, and notice of this will be given in due course.

Mr. W. H. Brown, the representative for the North Midland Centre of the Benevolent Fund, said a few words on behalf of the Fund, for which a collection was afterwards made.

A concert and wireless telephony demonstration then followed, which was thoroughly appreciated by all present.

Flame-Proof Mining Boxes.

The General Electric Company have recently developed a range of flame-proof lighting boxes for use with wire armoured V.I.R. cables in fiery mines, in which, by the use of only three standard forms of box and three types of glands, practically every lighting requirement in dangerous areas has been catered for. It will be seen from the illustration that these boxes are of robust construction. They comply in every respect with the regulations laid down in the Coal Mines Act, and among the important features in their design may be mentioned machined flanges of generous width on both box and cover, a simple locking device, and special attention to details of insulation. The armouring is clamped between two concentric cones, giving a large contact area and ensuring a firm connection and perfect continuity.



Universal Box with Detachable Glands and Well-Glass Fittings.

The Universal Junction box can be supplied as a one, two, three or four-way box with any one of three types of cover —(*a*) a solid front with central outlet tapped ½ in. gas and plugged ; (*b*) a cover for attaching a well-glass fitting ; and (*c*) a cover for attaching a bulkhead fitting. The solid front is supplied where the box is required merely as a junction box or where pendent lights are required. In the latter event, either a conduit drop with well-glass fitting or a cable gland with sealing chamber can be fitted. Two types of glands can be supplied, one forming an integral part of the box and the other detachable. The latter type can be removed, together with the sealing chamber by removing two bolts. In this manner connections or complete branch circuits can be prepared above ground and attached to boxes already erected. In the event of a failure renewals or repairs can be effected conveniently.

The third type of box is a split junction box for use with the mining-type lighting boxes when running cables are employed. By the use of split glands the cable may be tapped at any point and the branch circuit which can be made up complete, attached with the minimum interference with working.

I.E.E. : North-Western Centre.

At the Annual Meeting of the North-Western Centre of the Institution of Electrical Engineers last week the committee reported that eleven ordinary meetings and two special public meetings had been held, the average attendance at ordinary meetings being 115, and the average number of speakers at each discussion being nine. Four of the meetings were informal in character, and the committee felt amply justified in recommending their continuance during the next session. The membership was now 1343, an increase of 129 over the previous session. The following officers were elected :—Chairman : Mr. A. S. Barnard ; Vice-Chairmen : Mr. G. A. Juhlin, Mr. H. C. Lamb ; hon. secretary : Mr. W. A. Coates ; new members of committee : Messrs. A. G. Ellis, A. B. Mallinson, W. J. Medlyn, S. L. Pearce. Mr. Ellis had resigned the honorary secretaryship after three years of office, and Mr. W. A. Coates was elected to the post. The committee was gratified to record the election by the Institution of the assistant secretary, Mr. A. L. Green, as an Associate. Mr. Green had been connected with the North-Western Centre for twenty-one years. The Liverpool Sub-centre, founded in 1919, had a membership of 449, and the Students' Section had had a very active year. After the meeting Mr. J. W. Beauchamp, Director and Secretary of the E.D.A., gave a short lecture on Engineering Advertising, with special reference to the work of the E.D.A.

The Reform Club Kitchen.

The kitchen of the Reform Club, Pall Mall, is to be modernised and re-equipped this summer, and the contract for this work has been placed with Benham & Sons, Ltd., of Wigmore-street, W., who originally fitted up the kitchen in 1842, under the instructions of the famous chef, M. Alexis Soyer. Benham & Sons have in their possession a picture of the first equipment, and a few of the original fittings appear to be still in existence after eighty years. Mr. Stanley J. Benham, the present managing director, is the grandson of Mr. John Lee Benham, who carried out the contract in 1842.

Economic Conditions in Germany.

In the introduction to their report on the ECONOMICAL AND FINANCIAL CONDITIONS in Germany for the year to March, 1922, Messrs. J. W. F. Thelwall (Commercial Secretary to H.M. Embassy, Berlin) and C. J. Kavanagh (Commercial Secretary, Occupied Territories, &c., Cologne) state that there has been further progress towards order within the country; the more distressing features resulting from the war have almost completely disappeared; work has been plentiful and the resumption of overseas relations has taken place on a vast scale; but the bases of commercial life—stability of exchange and the granting of credit—are apparently as far from a satisfactory condition as ever.

Electrical Engineering.

The electrical trades were kept well employed on inland requirements, electricity supply and telephone extensions. The electrical transport developments have provided an appreciable amount of work, and the general activity in reconstruction throughout various industries resulted in a keen demand for plant and apparatus of all descriptions. The collapse of exchange in August led to a flood of orders for foreign account. The electrical groups of the Rhine-Elbe-Union concentration report that the community of interests agreement which they entered into with the steel producers has realised their expectations in greatly facilitating the supply of raw and semi-manufactured materials as regards quantity, quality, and regular delivery.

Research.

In the field of research and development in design the industry was as active as ever. Tests carried out on a gas turbine of a workable output are reported to have given satisfactory results, the development of the brown coalfield led to a stronger manufacturing capacity in specialised plant, and the overland h.t. transmission schemes gave a development to electrical apparatus required in this connection. The interest aroused by the low-temperature distillation of coal gave an impetus to the construction of plant, whereas the extension in the use of brown coal led to considerable attention to steam generators adapted to this class of fuel.

Electric Power.

The Rhineland-Westphalian industrial centre, together with its neighbouring districts, benefit from a very highly developed system of electric supply, and are calculated to receive an annual distribution from the supply stations of 13 milliard kWh, whereas the power generated on the mines and in the blast furnace and steelworks is estimated at 4 milliard kWh. The supply is chiefly in the hands of two large concerns, and augmented by the municipal stations of some of the larger towns, such as Duisburg, Dortmund, Oberhausen, Düsseldorf, Crefeld, Elberfeld, Barmen, and Cologne.

The chief private companies operating are the Rhenish-Westphalian Electricity Works, installed with 350 000 kW capacity, and the Communal Electricity Works Association, with 280 000 kW capacity. The former, which was originally formed with a capital of 2½ million marks, has now a share capital of over 100 million marks. In the initial stages its development was chiefly brought about by the absorption of various small supply stations, and more recently by the installation of new plant, of which the super-power station at Knapsack, operating on brown coal and having a turbo-generator capacity of 190 000 kW, represents its latest effort. An extension of the plant by a further 100 000 kW capacity has recently been decided upon, and it is proposed to install two 50 000 kW turbo-generators.

The impetus to its extension was given by the increased industrial demand for power and the development during the war of large electro-chemical factories. Its later development is interesting in point of view of the acquisition of certain coal interests, giving the company virtual control, and its extension into the field of gas supply, receiving coke-oven gas and distributing it throughout a length of 240 km. Hand-in-hand with the recent development, the company has assumed a new character by a majority participation of municipal interests, thus re-shaping it into a form of a mixed private and municipal enterprise. The Communal Electricity Works Association represents a merger of interests of ten different supply undertakings to promote economy in generating and distribution, to install new plant, to secure favourable deliveries of coal, and, while not encroaching upon the independence of the component companies, to consolidate their technical and financial interests.

Brown Coal.

An appendix to the report gives basic prices of coal in the Ruhr district and the price for Cologne brown coal. In spite of the low calorific value of the latter, the costs per potential heat unit delivered to the boiler bunkers is preponderatingly in favour of the lignite. These prices represent merely the official controlled prices to consumers, delivered at the pit mouth, whereas electricity undertakings having coal interests get their fuel considerably cheaper. The brown coalfields being adjacent to the power houses result in a considerable saving in handling charges, as the operation from mining to tipping into the bunker is completely mechanical. Carrying about 60 per cent. moisture, the transport of raw brown coal is not a commercial proposition, but when consumed on the spot, and the electrical energy transmitted by e.h.t. feeders, its importance as a cheap source of power is very appreciable. It is estimated that the power developed by brown coal and transmitted even into the Ruhr district from Cologne comes out very considerably cheaper than that generated at the Ruhr pit-head.

In the month of December, for example, Ruhr coal at the pit mouth was quoted at about M.500 per ton, as against brown coal at M.60, and, taking in an unfavourable case the calorific value of brown coal as one quarter that of steam coal, the price difference equals about 50 per cent. Having excellent briquetting qualities, it is possible for electricity works operating on lignite to develop a considerable turnover in briquettes both for industrial and domestic consumption, and so reduce the overhead charges. The problem of low-temperature distillation and recovery of by-products is the subject of active research.

Owing to the distance most of the large deposits are situated from centres of industry, it is possible that the future will see many extensions to the h.t. overland transmission schemes.

Rolling Stock.

Some tendency is apparent of the electrical firms engaged in locomotives to combine interests with manufacturers of rolling stock, and examples of this are to be found in the A.E.G.-Krupp, Rheinmetall, and Linke-Hofmann merger, and in the Rhine-Elbe-Union, which embraces the interests, amongst others, of the Siemens-Schuckert Works, the Bochumer Verein, and Dortmund Union. The reasons underlying these alliances might be found in a desire to concentrate upon plant for the electrification of railways, outside of the movement to secure a supply of raw materials.

P.O. Programme of Extensions.

ESTIMATES OF THE EXPENDITURE to be undertaken by the Post Office during the current financial year are given in a White Paper. It is proposed to spend £9 500 000 out of capital on the development of the telephone system. The sum of £2 230 000 is to be spent on trunk lines; £343 000 for extension of the overhead service; £3 500 000 for local works, the provision of subscriber circuits, junction lines, and public call offices; and £2 250 000 for new exchanges and the extension of existing exchanges, including sites and buildings.

The construction of two long underground routes will be put in hand, namely, from Leeds to Edinburgh, *viâ* Darlington, Newcastle, and Jedburgh, and from Worcester to Bristol *viâ* Gloucester. Among the shorter and more important extensions of the existing underground system which will be begun or completed are the following new routes:—London to Southend, Bristol to Bath, Manchester to Preston, Preston to Lancaster, Bradford to Dewsbury, Colchester to Ipswich, Pontypool to Abergavenny, Swansea to Pontardawe, Glasgow to Whitecraig, Kirkintilloch and Kilsyth and Edinburgh to Kirkcaldy. The new overhead trunk circuits will number about 200.

Local Developments.

In connection with the local development works, underground ducts and cables will be laid in various parts of London and in a large number of towns, including Colchester, Cambridge, Tunbridge Wells, Brighton, Nottingham, Derby, Birmingham, Liverpool, Manchester, Leeds, Halifax, Edinburgh, Glasgow, Aberdeen, and Falkirk. The scheme for new exchanges and the extension of existing exchanges includes the installation of equipment for about thirty new exchanges, and for the extension of some forty of the more important existing exchanges.

A new exchange is to be provided in Central London near the Monument, and the work is to be begun at once. In the outer suburbs exchanges will shortly be open at Tottenham and Barnet, and equipment is to be provided for new exchanges at Eltham, Kilburn, Southall, Nunhead, Woodford, Wallington, Addiscombe, Thornton Heath, and Hounslow. In the country the work will include new exchanges at Ramsgate, Eastbourne, Southampton, Swansea, Birmingham, Sheffield, Buxton, Liverpool, Inverness, and Dundee.

The Automatic System.

Provision is made for a considerable extension of the automatic telephone system in the working of the new exchanges at Southampton, Gloucester, Swansea, Sheffield, Shrewsbury, Fleetwood, Dundee, and Kirkcaldy, all of which will be equipped with automatic plant. The equipment will also be extended at the automatic exchanges already existing at Epsom, Newport (Mon.), Chepstow, Leeds, Accrington, and Darlington.

Expansion of Hydro-Electric Business.

In May, 1920, Sir W. G. Armstrong, Whitworth & Company initiated a hydro-electric section as a part of their civil engineering department to secure orders for water turbines, to be manufactured at their Elswick works to the designs of a well-known Norwegian firm. The business of this section has so expanded that the firm formed in January last a separate HYDRO-ELECTRIC DEPARTMENT, as a unit apart from the civil engineering department. The new department, like the old section, is dealing with complete water-power development schemes throughout all the various stages, in addition to the various component parts of such schemes, civil engineering, mechanical and electrical. Messrs. Armstrong now have survey parties out in many parts of the world looking into projects which have been brought before them. The offices of the hydro-electric department are at 8, Great George-street, Westminster, S.W. 1, and the department is under the management of Mr. Douglas Spencer, assisted by Mr. Robert P. Tod and Mr. V. Bataillard, and a large staff.

Factory Magazines.

More than sixty editors of works magazines or "factory newspapers" attended the second Conference of Editors of Works Magazines at the offices of the Industrial Welfare Society last Friday, Mr. Robert R. Hyde (Director of the Industrial Welfare Society) presiding. It is clear that magazines of this kind, if well edited and organised, will prove a valuable stabilising influence in industry. They form a common platform, where all sides can voice their views. Papers were read by Mr. Reginald Pugh (editor of "Industrial Welfare"), Capt. J. Robinson ("Smiths' Dock Monthly"), Mr. E. M. Wright (Sir Wm. Beardmore & Company), Mr. T. B. Rogers ("The Employees' Own Magazine"), and Mr. Oliver Sheldon ("Cocoa Works Staff Journal"). The general opinion was that the factory magazine should be non-political, and that it should contain no deliberate propaganda of any kind. Although the conference was mostly concerned with magazines for general circulation among the employees of large firms, an instructive paper was read on the subject of "An Administrative Staff Magazine" by Mr. Oliver Sheldon, who emphasised the importance of placing essential facts concerning their own firms and industry generally, not only before directors, managers, and departmental heads, but before foremen and others who come into more direct contact with the workers. One firm is publishing a magazine for this purpose.

At the luncheon, over which Mr. Sam Mavor (of Mavor & Coulson) presided, Sir Ernest Benn, who opened the first conference eighteen months ago, said, in the course of his speech, that he understood that the fashionable "axe" had had its effect on the works magazine, and that some of the magazines had been subjected to the operation of economy in the last twelve months. There was nothing he could conceive of as so foolish as the cutting down of that sort of work.

He referred to the deterioration which was now taking place in the general Press, and expressed the opinion that the time was not far distant when the trade and industrial Press would be the sole remanant of all that was worth having in the arts and practice of journalism. Works magazines should avoid politics, as the word was commonly understood, but they might be able to supply the facts to educate the people in the principles of commerce and industry, and thus obtain a greater influence than if they entered into politics as such. Through works magazines they might get at the rights of Communism. As an example of the methods of Communists, he related a true story of an occurrence in Russia during the first revolution, when one of the first proceedings of the workers who took over a factory was to go to the offices to collect the capital.

It was decided to hold the next Conference not later than a year hence.

Chester Electricity Inquiry.

On behalf of the Electricity Commissioners, a public inquiry was held last week at Chester into an application by Chester Corporation for a Special Order to authorise them to supply electricity within the urban district of Hoole, parts of the rural districts of Chester and Tarvin, and a part of the rural district of Hawarden.

On behalf of the Corporation, it was stated that they had plant with 7 396 kW capacity. The maximum demand for electricity during the winter of 1920-21 was 2 282 kW. The Corporation had expended on their undertaking £236 000, of which £193 380 had been provided by loans and £42 620 had been contributed out of the surplus revenue of the undertaking. At present they had 2 500 consumers taking 4 000 000 units per annum, from which an income of £48 000 was received. The electricity produced at the Hydro-Electric Works had a substantial bearing upon the cheapness at which the Corporation could give supply. The present charges were 5¼d. per unit for lighting, and from 2¼d. to 1½d. per unit for small power demands; but for large power consumers, taking not less than 25,000 units per annum, the charge was £6 per kW demanded per annum, plus 0·75d. per unit. There was also a special tariff for domestic purposes of 15 per cent. of the rateable value plus 1d. per unit. Mr. S. E. Britton, city electrical engineer, estimated the capital cost of the compulsory works scheduled in the Order for Hoole and Newton at £7 000, but to deal with the agricultural area £38 725 was required, making a total of £45 725. The charges would depend upon the demand. If the demand was not more than 200 000 units per annum the average per unit would be 11d.; for 250 000 units, 9d.; 355 000, 6d.; 550 000, 4d. He estimated that 500 000 units would be sold during the first year.

On behalf of Flintshire County Council, it was urged that Chester Corporation were attempting to poach on the preserves of the North Wales Power Company, whose scheme had been approved by the Commissioners, and to set up another authority.

Mr. Miller, for the North Wales Power Company, said that the whole trend of the present inquiry suggested a determination to reverse, if possible, the decision of the Commissioners that a big area should be developed by means of the hydro-electric power of North Wales. He contended that the present was not an application which deserved consideration on its merits.

Owing to the splendid response to the invitations issued for the Electrical Engineers' Ball on Feb. 10 last, the sum of 55 guineas has been handed over to the Institution of Electrical Engineers' Benevolent Fund and 55 guineas to the Electrical Trades Benevolent Fund.

Legal Intelligence.

An Electric Furnace Dispute.

The hearing was resumed on Monday, before Mr. Justice Sankey, of the action, the hearing of which was begun in February. The plaintiffs, Electro Metals, Ltd., sued the Malleable Steel Castings Company (1909), Ltd., to recover £1 239 4s. 7d., balance of purchase price of a 30 cwt. electric smelting furnace sold to defendants in May, 1918. Defendants' case was that the plant was unsatisfactory; they alleged plaintiffs failed to comply with certain conditions, and they counter-claimed for loss suffered by the alleged defects of the plant.

Mr. T. W. H. Inskip, K.C., and Mr. Wilfred Lewis were for plaintiffs; and Mr. T. Eastham, K.C., and Mr. R. Bennett represented defendants.

It was explained at the previous hearing that the price of the furnace was £3 300, and the sum now claimed was an instalment of £1 100 and the cost of certain materials required in connection with the furnace which had not been supplied under the contract between the parties, but which plaintiffs ordered at the request of defendants. The furnace had not been used since the moulders' strike in 1919, when the men working it were forcibly driven from the building by the moulders, and it was said that parts of the machinery had perished. Defendants admitted that the furnace was received and set up, and that it was seen by plaintiffs' metallurgist, Mr. Needham, before it was got into working order. Defendants relied on a number of alleged breaches of the contract or warranties; they said that plaintiffs warranted that the furnace should be capable of producing straight steel of a tensile strength of 40 tons to the square inch, and 15 per cent. elongation unannealed; that it would produce steel entirely to defendants' satisfaction, and would not use more than 800 units of electricity per ton of metal melted.

Defendants said that these warranties were not complied with. Plaintiffs denied the warranties, and said the furnace was capable of doing what, under the contract, it was said it would do.

A considerable body of evidence had been given at the previous hearings, and the only witness now remaining was Mr. Edward A. Walsh, director and works manager of defendants, who referred to the giving of the alleged warranties, and said that they were never able to use the furnace successfully; as a commercial proposition it never produced steel suitable for steel castings, nor did it produce steel using 800 units per ton in the ladle.

After counsel had addressed the Court, Mr. Justice Sankey said it was alleged that plaintiffs warranted that the furnace would produce steel of tensile strength of 40 tons to the square inch and 15 per cent. elongation unannealed, but, on the whole, he could not conclude that any such warranty was given. The making of steel castings was an expert work, and he did not think that Mr. Walsh had adequate knowledge of those matters. He thought there was a guarantee that the consumption of electricity would be about 800 to 850 units for continuous working, but he was of opinion he could not find if there had been continuous working or that the guarantee would have been complied with. He was satisfied, on the whole, that the furnace was fitted for its work, but it was a long time being got into proper order, and defendants were entitled to recover as to certain expenditure for wages, electricity, &c. He gave plaintiffs judgment on the claim for £1 139 14s. 7d. and costs, and on the counter-claim he gave defendants judgment for £289 16s. 2d. and half the costs of the counter-claim.

Improper Use of Electricity.

At the Bradford Police Court last week, Harry Wilkinson, a builder, was charged with stealing electricity, the property of the Bradford Corporation, and William W. Threapleton was charged with laying an electric line communicating with another electric line, the property of the Corporation.

Mr. W. H. Leatham, who prosecuted, said it was difficult to say what was the value of the electricity alleged to have been taken. It was probably under £5, but for the purpose of jurisdiction he put it at £2. The defendant Wilkinson had built a house for himself at Baring-avenue, and Threapleton was an electric light contractor. Having described the procedure necessary for obtaining a supply of electricity, he said that Wilkinson applied for electricity in August, 1921. His house being further away from the cable than usual, the Corporation required him to agree to take a supply for five years instead of the usual two years, and to take current to the minimum value of £20 a year. He agreed to that. On Dec. 29 last a service cable was laid to the house and a service box installed. On Jan. 2 a meter was fixed, and that completed the business of the Corporation. They waited for the receipt of the test notice, which never came. The seriousness of the case was that if the wiring installation was not in order, and if it was connected up with the Corporation cables it might cause a fuse, with considerable damage over a great distance in the mains. When the meter was put into the house Threapleton was present. Two Corporation servants lived in the district, and they noticed that between Jan. 2 and March 10 the house was brilliantly lighted with electric light. Inquiries were made, and an inspector, who was sent to the house on March 10, found the service box had been broken and the installation connected direct to the service cable. He suggested that Threapleton had connected the wire direct to the service box without giving the required notice, and he also suggested that Wilkinson knew what he had done.

The Stipendiary Magistrate: You cannot assume that every householder who employs a man to put in an installation has guilty knowledge.

Mr. A. V. HAMMOND, who defended, asked permission to withdraw Threapleton's plea of "Guilty," and the magistrates agreed.

After Mr. Charles Gillin, mains manager for the Electricity Department, had given evidence,

The defendant WILKINSON said he had no knowledge of electrical fittings, and left everything to Threapleton. He had several times complained about the delay.

THREAPLETON said the connection was made on the morning the inspector found it. It was connected for testing purposes only. The testing instrument broke down, and the only alternative they had was to connect it up to the service pipe.

The STIPENDIARY MAGISTRATE said that on the face of it it looked very much as if Wilkinson must have known what was being done, and that his installation was being connected improperly without going through the meter. The Bench were not satisfied that Wilkinson was guilty of larceny, and the summons against him would be dismissed. Threapleton must have known he was doing wrong in making a connection in such a way that the current would not pass through the meter, and he would have to pay the maximum fine of £5.

At LARNE Petty Sessions on the 25th ult., Hugh J. M'Kerrell, proprietor of a motor garage, was charged by the Larne Electric Light Company with fraudulently obtaining a supply of electricity from the company's main.

It was stated that an employee of the company found two wires connected with the company's main and leading into defendant's garage, being there connected to a 100 W fixed lamp, to a portable lamp of 40 to 60 W, and a board for the charging of accumulators erected in the wall. The current for these lamps did not pass through the meter. For the quarter ending Dec. 31 defendant's meter only registered six units, but collectively the lamps on his premises would consume one unit in 2½ hours.

Defendant, who said he had only connected the wires on the previous night in order to get a light into the oil store, was sent for trial to the Quarter Sessions.

Telephone Pole Rental.

On Monday the Railway and Canal Commission Court (Mr. Justice Lush, Mr Tindal Atkinson, K.C., and Sir Lewis Coward, K.C.) delivered judgment in a re-heard action which recently came before Judge Crawford (at Romford County Court), and who fixed the rent of some telegraph poles on private land at Grays, Essex. The County Court Judge had fixed the rent of several poles at 5s. each, of some at 15s., and one at £1.

In delivering judgment, Mr. Justice Lush said the case raised a question of general importance as to the position and rights of the Postmaster-General with regard to the construction and maintenance of telegraph poles and wires. It was the first case under the Telegraph Construction Act of 1916, which enabled the Postmaster-General to apply to the court for a compulsory order if the owner refused his consent to having the posts on his land. The Act of 1916 brought the land of private owners within the range of the limited compulsory powers previously conferred on the Postmaster-General. Certain posts and wires were erected under an agreement between Mr. Brooks and the National Telephone Company; that agreement having come to an end, a difference arose between Mr. Brooks and the Postmaster-General, and that difference was referred to Judge Crawford, who made an award. The Postmaster-General was dissatisfied, and applied that it should be referred to that court. In his Lordship's opinion, a mistake had been made in the procedure adopted. It was never intended that a dispute as to the compulsory entry on land of a private owner should be referred to a magistate or County Court judge in the first instance, and Judge Crawford had no jurisdiction in the matter. Mr. Brooks had properly admitted that the question was only as to the terms and conditions under which his consent should be given. The poles were on woodland and near a private road, which was also his property. If the convenient user or enjoyment of the land was interfered with, such interference was subject to proper consideration. The land in question had a valuable bed of chalk under it, which would shortly be developed or sold in order that the chalk could be worked, and Mr. Brooks' chief complaint was that it would be a serious inconvenience to him, and would certainly cause him loss as a prospective vendor of the land to have those obstructions there. His Lordship thought that the amenities of the land were substantially affected by the existence of the posts and wires, and particularly in respect of three of the posts a substantial payment ought to be made. He held that the sum of 5s. each ought to be paid for all the posts, except those three. For two of the latter 10s. each should be paid, and for the third 20s. He did not think that these sums were excessive when the posts and wires were carried right across a wood, with a right to entry on the land. Moreover, the Postmaster-General had the advantage of taking these short routes for his telegraph wires. The present case must not be treated as a precedent applying to all cases. If a landowner made an unreasonable demand, which was successfully resisted, the court had power with respect to the costs, and the owner might have cause to regret making his claim.

Mr. Tindal Atkinson and Sir Lewis Coward concurred.

As Mr. Brooks said he had not incurred any substantial costs, no order as to costs was made.

Action Over Electrical Installation.

Before Mr. Justice Rowlatt on Monday Mr. George Pittman, electrician, sued Mr. Jerome W. May and Mr. Samuel Walbrock for £200 for electrical installation work at the Brixton Hall, and suggested that he found, after the instructions of Mr. May, that the defendants were in partnership as the Brixton Dancing Palace, Ltd., but he knew nothing of the company till he received a notification from its receiver and manager. The receiver said he had surrendered the lease as he was unable to pay the rent. Mr. May stated that he acted, and to plaintiff's knowledge, as agent for the Brixton Dancing Palace, Ltd., and Mr. Walbrock that he was never in partnership with Mr. May.

His Lordship, in giving judgment, said the question was whether the electrician was employed by Mr. May personally or employed by Mr. May on behalf of the company. The dispute showed how important it was that a contractor, when he was asked to do work, should say, "Who am I doing it for?" and if he was told it was a company, he ought to find out whether it was worth the money. The electrician had done work at Mr. May's own house. In respect of the work in question, May asserted, and plaintiff denied, that there was mention of the company. The documents were against plaintiff. He addressed Messrs. The Brixton Dancing Palace, and received three cheques signed by the company. Plaintiff said he did not notice the company's name on a document, but persons should notice things in business, and that showed him as clearly as possible that the persons to whom he was giving a receipt were the Brixton Dancing Palace, Ltd., and that the rest of the money was to come from them. He might have said, "The contract was with May; I am not going to have it altered now." He did not, and he did not see May till the company had practically gone to pieces. His Lordship did not feel justified in giving him a judgment against May. Judgment must, therefore, be entered for the defendants.

Weston Electric Lamp Company v. Baldes.

Last week Judge Cluer, in the Shoreditch County Court, heard an action, brought by the Weston Electric Lamp Company against Mr. C. Baldes, for the recovery of £2 7s., balance alleged to be due on the purchase price of an electric vibrator. There was a counterclaim for £2 1s., amount paid as a deposit, as it was alleged the vibrator was not up to guarantee. It was stated that defendant paid a deposit of £2 when he purchased the machine on May 31 last, since which time he had not been heard of.

LOUIS SUBTIL, clerk to plaintiffs, said that instalments should have been paid monthly. Defendant cross-examined to show that he paid a deposit of £2 instead of the usual 5s., and agreed to pay the balance in a month if the vibrator was satisfactory, but in three weeks it was useless, so he wrote to plaintiffs to that effect on August 18 and 22, and November 9. Plaintiffs' witness said they never received the letters.

JUDGE CLUER: A business man does not copy letters in a book, and then not post them. He then read the guarantee off the box, which was for a year, by the Fitzgerald Electrical Company, of Toronto and Conn., U.S.A.

DEFENDANT, in his evidence, said he was being constantly asked for the money, but he ignored the demands, as they took no notice of his letters of complaint.

Judge CLUER said there would be judgment for the defendant on the claim, and on his counterclaim for the return of the £2 deposit. "I should like to add," he went on, "that it is a gross untruth to say these letters were not received, and it is a misfortune that a tradesman in this district should send anyone to say such a thing."

Telephone Charges.

At Brighton County Court on the 27th ult. Judge Moore Cann heard an action by the Postmaster-General against Mr. Gordon H. Boswall Preston for the recovery of £22 9s. 4d., telephone rental fees and deposit alleged to be due under an agreement dated May, 1921.

It was stated that the service had been disconnected in consequence of defendant's failure to pay his account, but, notwithstanding the interruption in the service, defendant remained liable for rental, &c.

For the defence it was urged that defendant was willing to pay up to the time of disconnection, but it was contended that the Postmaster-General had no *locus standi* as a corporation to sue or be sued, and that the certified account of telephone charges which had been put in was not sufficient proof of the amount due.

The judge decided that the Telegraph Act of 1878 gave power to the Postmaster-General to sue as if he were a corporation. On the second point his honour held that a certificated account was not sufficient proof of charges, but he was of opinion that under the clause in the agreement the Post Office was entitled to the amount of outstanding rental. Accordingly he gave judgment for £14 9s. 9d.

Kelly v. Alexandra Clothing Company.

In the Shoreditch County Court on Tuesday, before Judge Cluer, Messrs. Kelly & Tarshis, electrical engineers, sued the Alexandra Clothing Company to recover £15 6s., balance of an account for £70 6s. for electrical work carried out.

Mr. TARSHIS gave evidence, and said that they fitted defendant's factory for lighting and power. He supplied a motor and starter for £25. A question arose about a radiator, but he denied that he had ever promised to take it back, as defendants had spoiled it themselves. They had laid it on its side, heated a kettle on it; the water had run over, causing "shorts." The electric lights in the office went wrong, but that was due to a leaky roof and not bad work.

In cross-examination, witness denied that he agreed to send a 3 H.P. motor for £25, but only a 2 H.P.

The defence was that the price had been agreed at £18 for a 2 H.P., which plaintiffs declared they could not get. Finally Mr. Tarshis said he could get a 3 H.P. for £25, to which defendant agreed, but he sent in a 2 H.P. after all. One of the radiators was intended for heating, but there was no heat from it.

Judge Cluer found for plaintiff for £3 16s. only, with costs.

Parliamentary Intelligence.

Grampian Electricity Scheme.

On Tuesday a Select Committee of the House of Commons, presided over by the Hon. W. Ormsby-Gore, commenced consideration of the Bill to authorise the incorporation of a company to construct hydro-electric works, to utilise the waters of Loch Ericht, Loch Rannoch, Loch Mihairg, Loch An Duin, Loch Garry, Loch Seilich, Loch Cuach, and certain rivers in their vicinity, and to supply electricity in the counties of Perth, Kinross, Forfar, Argyll, Stirling, and Inverness.

Mr. W. E. Tyldesley-Jones, K.C., opening the case for the promoters, said the area covered by the scheme was recommended as a desirable one by the Committee on Water-Power Resources in July, 1921. In all cases under the scheme the water would be discharged back into its natural waterway within a reasonably short distance from the places where it was diverted. There was under discussion with the Board of Trade a clause giving the State the right to acquire the undertaking at a certain date, provided such terms would not preclude the possibility of the company being able to raise capital. Last year the promoters deposited a Bill for substantially the same scheme, but withdrew it because one of their counsel retired and another was suddenly taken ill, and the negotiations with some of the landowners were not in an advanced stage. The British Aluminium Company also deposited a Bill last year which conflicted somewhat with that of the present promoters, and the result was that last year's Bill was ultimately dropped. The promotion of the present scheme was originally started by the British-Italian Corporation, and the present promoters, the Hydro-Electric Development Company, Ltd., were representative of those interests, and its shareholders included the British-Italian Corporation, the London County, Westminster & Parr's Bank, Wallace Bros. & Company, the British Steamship Investment Trust, Sir Henry Babington Smith, Sir Austin Harris, Mr. Ernest Cox, and Mr. Manzi Fe.

There were 31 petitions deposited against the Bill, but only three were left. The Spey Fisheries Board had been satisfied by the insertion of a clause requiring the company to main a certain flow in the river, and Dundee Corporation had withdrawn their opposition upon the insertion of a clause precluding the company from supplying in the Corporation's area of supply except for railway purposes. The three petitions remaining were those of three landowners, Mrs. Laterriere, the trustees of Col. Macpherson, and Sir George Macpherson Grant. The pomoters did not desire to oppose the granting of reasonable compensation to landowners whose property was injuriously affected. The estimated total cost of the scheme was 4½ millions, exclusive of generating plant, cables, &c., but in the early stages it was only proposed to raise one million in share capital, and power was sought to borrow 2½ millions. The four generating stations which it was proposed to build would generate 56 000 h.p. Counsel gave a brief outline of the proposed works, and evidence in support of the Bill was then given.

The promoters' case had not concluded when we went to press.

Sheffield Telephone Exchange Contract.

In reply to Mr. Manville, who asked (House of Commons, April 27) if the First Commissioner of Works was aware that a contract for the construction of the buildings of the new telephone exchange in Sheffield had been let by the Office of Works to the Wholesale Co-operative Society; and was it to be the policy of the Government in future to place contracts in the hands of this or similar organisations, which, under the present system of taxation, contributed nothing to the maintenance of the country, Lieut.-Col. Sir J. Gilmour (for the First Commissioner of Works) said that a contract for preliminary work upon the site for a new telephone exchange at Sheffield had been let to the Co-operative Wholesale Society, which submitted the lowest competitive tender. The Office of Works was satisfied that the firm was capable of executing the work in accordance with its requirements as to time and quality of craftsmanship. The decision was based on the general policy of economy. This consideration was entirely separate and distinct from any question as to the taxation of co-operative societies. On that question he referred Mr. Manville to the evidence given before the Royal Commission on the Income Tax and to the Report of the Commission published in March, 1920 (Cmd. 645), from which he would find that the suggestion contained in the last part of his question was based upon a misapprehension.

Imperial Wireless Chain.

In reply to Mr. Hurd (House of Commons, April 26), the Postmaster-General (Mr. Kellaway) stated that the only Dominion which had entered upon any wireless project of its own was Australia, whose representative at the Imperial meetings of last year reserved to the Commonwealth Government full freedom of action to decide in what manner it would co-operate in the Imperial wireless scheme. Precise information as to the project of that Government was not yet to hand, but when it was received its bearing on the remainder of the scheme would be carefully considered. The Indian Government had stated that they would have difficulty in finding funds to erect a high-power station of their own, and the position thus created would also be examined. Communications were proceeding with the Union Government, and the Canadian Government were sending two representatives to this country to discuss the matter. (Since the above date two offers, one by a British and the other by an Indian firm, have been received to construct and work a direct wireless service between India and Great Britain under licence and in accordance with Government requirements.)

Miners' Safety Lamp Glass.

In the House of Commons on Friday, Mr. Bridgeman introduced a Bill to restrict temporarily the powers of approving safety lamps under sec. 33 of the Coal Mines Act, 1911.

The Bill is intended to carry out a pledge given by Mr. R. McKenna, when Home Secretary, in regard to glass for miners' safety lamps. The glass came from Austria and Germany, and Mr. McKenna promised that British makers, in consideration of their laying down plant and erecting factories, should be relieved from foreign competition for three years after the official close of the War. Hitherto foreign glass has been excluded on the ground that it was of a "type" that would interfere with British-made glass. But it has been found that "type" does not, from a legal point of view, include place of origin, and the present Bill seeks to put this right, but a clause provides that the British glass must be adequate in quantity and quality.

Telephone Call Boxes.

Replying to Sir H. Brittain (House of Commons, April 26), Mr. Kellaway stated that the total number of public call-office stations at March 31 last was 15 874. The total revenue, exclusive of trunk calls, collected from public call offices during the past financial year was £490 000. No separate account was kept of the cost of maintaining call offices, but the operating was expensive where coin boxes were fitted, as was usually necessary, and there was, no doubt, some loss on this branch of the service.

Machinery Rating Bill.

That hardy annual, the Machinery Rating Bill, was read a second time in the House of Commons on Friday, and committed to a Standing Committee. This is the twentieth time the Bill has been introduced, and we are afraid, as it is a private member's measure, it will have the same fate as its predecessors.

Morecambe Corporation Tramways Bill.

The Bill to confirm the Morecambe Provisional Order was read a first time in the House of Commons last week.

Electricity Supply in South-Western Victoria.

The Victorian Electricity Commission state, in a report on electricity supply for the South-Western District of Victoria, that the population of the district is about 65 000, and Messrs. Lincolne, MacDougall & Demaine estimate that, at the outset, about 40 per cent. of this population would be served by the undertaking. Three alternatives have been considered: (A) A self-contained scheme, including a steam-driven plant within the district; (B) a transmission line passing through the main centres of population and taking current from the Melbourne Electric Supply Company.; and (C) a similar transmission line receiving its energy from the Government's Morwell undertaking. In regard to (A), with a generating plant at Warrnambool, the cost of the station, including two 750 kW generators, would be £76 400, and the cost of transmission lines and sub-stations £32 420, making a total of £108 820. The Commissioners are, however, of opinion that under (A) Camperdown and Terang would not obtain their requirements, except at a higher cost than under (B) or (C), or from their existing plants, and the average cost to the whole district would be higher than under (B) or (C). (B) and (C) are on identical lines as far as the district west of Geelong is concerned, but under (B) the supply would be immediately obtained from Geelong, while under (C) the supply of Morwell energy would later be made available at Geelong by a line from Newport. The estimates provide for a 44 000 V transmission line, consisting of a single circuit of aluminium conductors, steel reinforced and carried on wood poles. The price (under B) quoted by the Melbourne Company is £3.7 per kW per annum, plus 0.67d. per kWh, while in the case of (C) the estimated average price at which energy could be supplied at the Newport terminal of the Morwell line is £5·05 per kW per annum, plus 0.073d. per kWh, but this should be reduced if the Newport-Geelong line were at some future time called upon to supply in Geelong and neighbourhood, as well as the western district. The total capital cost of (B) is estimated at £117 120 and of (C) at 139 280, including in both cases an import duty of 10 per cent. on the aluminium conductors, but if the duty should be 45 per cent. the figures would be £122 130 and £145 810 respectively, and the annual expenditure would be £23 490 for (B) or £20 479 for (C). Assuming 45 per cent. duty on the conductors, the average price at which energy could be supplied to the towns to be served would be 4.21d. under (B), or 3·67d. under (C) for the south-western district only, or 3·32d. including supply in Geelong district.

The Commission recommend that, as a first step in the ultimate linking up of the South-Western district with the projected State bulk supply scheme from Morwell, the supply of energy to the south-western district be provided by the construction by the Commission of a transmission line from Geelong to Warrnambool, with an extension to Koroit and Port Fairy; and that a contract be entered into with the Melbourne Electric Supply Company for the supply of the whole of the electrical energy required for the recommended scheme at the rates quoted by the company for a period not exceeding five years.

Electricity Supply.

The annual accounts of NELSON (Lancs.) electricity undertaking show a deficit of £6 000.

The Minister of Transport proposes to confirm the NEWPORT (MON.) ELECTRICITY (EXTENSION) SPECIAL ORDER, 1922. Any objections must be sent to the Ministry of Transport by May 22.

At a meeting of the WARRINGTON Electricity Committee last week it was stated that applications for electricity had been received from several local firms and from the L. & N.W. Railway, who intimated that if they could not obtain supply they would apply to the Commissoners for an order to enable St. Helens to supply them with electricity.

To meet the growing demand for electricity, the STALYBRIDGE, etc., Joint Tramways and Electricity Board have sanctioned the installation of a 6 000 kW turbine. It is stated that the demands for current have increased so much that when trade revives and the mills in the four districts go on full time, the Board will have to ask the millowners to work some of their machinery during the night.

Mr. Williams, manager of Edmondson's Electricity Corporation, has asked ELGIN Town Council for their consent to an application by the company for a Special Order to supply electricity to the district. If the council's consent is obtained it is proposed to form a public liability company, called the Elgin Electrical Supply Company, Ltd., with a capital of £25 000, half of which, it is hoped, will be subscribed locally. The Council have appointed a committee to consider the matter.

BLACKPOOL Electricity Department generated 8 825 371 units during the year ended March 31, an increase of 256 848 over the previous year. New connections numbered 574, bringing the total up to 4 932. The estimated profit for the year, after providing for capital charges, is £10 000. The demand for electricity is increasing so rapidly that a big scheme of extensions is proposed, and the Electricity Commissioners on Monday held an inquiry into the Corporation's application for sanction to borrow £220 000.

According to a report prepared by Mr. E. Moxon, borough electical engineer of SOUTHPORT, nearly £70 000 is required for extensions and alterations to the municipal electricity works to meet the rapidly increasing demand for electricity. Between 1919-1922 the increased consumption averaged 333 300 units per annum. Mr. Moxon recommends the addition of a 1 500 kW three-phase turbo-alternator to the generating plant, which consists of two 3 000 kW turbo-alternators. He proposes to reorganise the distributing network and the equipment at a number of the more important sub-stations in the centre of the town. The total estimated cost of the schemes amounts to £69 881, and it will take three years to carry out the whole of the work.

The Minister of Transport proposes to confirm (1) the ISLE OF WIGHT ELECTRIC LIGHT AND POWER COMPANY SPECIAL ORDER for the amendment of the Bonchurch Electric Lighting Order, 1900; the East Cowes Electric Lighting Order, 1901; the Cowes Electric Lighting Order, 1902; the Carisbrooke and Northwood Electric Lighting Order, 1903; the Ventnor Electric Lighting Order, 1897; the Sandown and Shanklin Electric Lighting Order, 1899; and the Newport (Isle of Wight) Electric Lighting Order, 1899, by making provision for revision of the maximum prices authorised to be charged thereby; (2) the URBAN ELECTRIC SUPPLY COMPANY SPECIAL ORDER for the amendment of the Berwick-upon-Tweed Electric Lighting Order, 1900; the Redruth Electric Lighting Order, 1900; the Dartmouth Electric Lighting Order, 1900; the Illogan Electric Lighting Order, 1903; the Kingswear Electric Lighting Order, 1913; the Godalming Electric Lighting Order, 1896; and the Glossop Corporation Electric Lighting Order, 1899, by making provision for the revision of the maximum prices authorised to be charged thereby; (3) EDMUNDSON'S ELECTRICITY CORPORATION SPECIAL ORDER for the amendment of the Dorking Electric Lighting Order, 1897, and the Cromer Electric Supply Order, 1899, by making provision for the revision of the maximum prices authorised to be charged thereby; (4) the ALDERLEY AND WILMSLOW ELECTRIC SUPPLY SPECIAL ORDER for the amendment of the Wilmslow Electric Lighting Order, 1903, and the Alderley Edge Electric Lighting Order, 1905, by making provision for the revision of the maximum prices authorised to be charged thereby; and (5) the LYMINGTON ELECTRICITY (AMENDMENT) SPECIAL ORDER for the amendment of the Lymington Electric Lighting Order, 1899, by making provision for the revision of the maximum charges authorised to be charged thereby. Any objections to any of the proposed new orders must be sent to the Ministry of Transport by May 13.

New Schemes and Mains Extensions.

ABERDEEN Town Council have passed the plans for the new boiler-house extension at Dee Village-road. The estimated cost is £11 000.

BARNSTAPLE Town Council has received sanction to loans of £2 100, for condensing plant at the Electricity Works, and £1 500, for mains, services, and meters.

LUTON Town Council is applying for a loan of £3 733, for transformers and switchgear, and £8 267, for trunk cables, in connection with a supply of electricity in bulk from the North Metropolitan Electric Power Supply Company.

A public inquiry was held at NAVAN (Ireland) last week into a scheme of the Urban Council to establish electricity supply works in the town. It was stated that the cost would be £9 991, and no objection was raised by the ratepayers.

The decision of the Electricity Commissioners into the schemes for the reorganisation of electricity supply in the NORTH LANCS AND SOUTH CUMBERLAND electricity district is not expected until June, as the Commissioners have been busy on other work.

ROYTON District Council have decided that they have waited long enough for Oldham to supply them with electricity, and have appointed a sub-committee to meet representatives of Crompton Council in order to see if some joint scheme for supplying the districts cannot be decided upon.

At a meeting of BROWNHILLS Urban Council last week it was reported by Mr. C. Jones (electrical engineer to the Cannock Chase Colliery Company) that the company had decided to proceed with the scheme for supplying Chasetown, Chase-terrace, Burntwood, and Hammerwich with electricity. For private purposes the charge would be a maximum of 8d. per unit for lighting, and for public lighting the suggested charge was £3 per lamp per annum for the Brownhills West district and £3 5s. for the remainder of the Brownhills area. The company would bear the cost of the cables and standards. The council expressed its full sympathy with the scheme.

Alteration of Charges.

BARNSTAPLE Town Council has reduced the price of electricity for lighting to 9d. per unit, and for power to 7d. per unit.

WARRINGTON Electricity Committee announce a reduction in the price of electricity of 20 per cent. for power and heating, and of 10 per cent. for lighting and traction.

GRAVESEND Town Council have decided to reduce the electricity charges. As from March 31 last the flat rate has been reduced to 8½d. per unit, and the other rate from 80 to 75 per cent. over the pre-war figure. The minimum charge for the June and September quarters is to be 10s. per quarter, and for December and March 15s. per quarter.

MANCHESTER Electricity Committee have agreed to recommend the Council to make a slight reduction in the electricity charges as from the June quarter. The amount is not fixed. During the past year it was reported there had been an approximate net profit of £43 229, after meeting all capital charges and income tax, and this amount is to be placed to reserve account.

BIRMINGHAM Electricity Committee have decided, as from March last, to reduce the prices for l.t. supplies by ½d. per unit in the case of ordinary lighting, and by ¼d. for power supplies. The Committee report that there has been a marked improvement in sales during the past few months. There has already been a substantial reduction in the prices for manufacturing prices under contract.

The CITY OF LONDON ELECTRIC LIGHTING COMPANY announce the following reduced tariff :—For lighting, 8d. per unit in the winter quarters for the first eight units per 30 W connected, and 4d. per unit for all energy consumed in excess, and in the summer quarters 8d. a unit for the first four units per 30 W and 4d. after; for power, 1 2-3d. per unit, plus a fixed charge of 10s. a quarter per kW of connected demand; heating, 1½d. net per unit.

The following revised scale of charges for electricity for lighting purposes has been approved by CANTERBURY Town Council, the charges to become effective as from April 1 :—Up to and including 4 000 units per quarter, 8d. per unit; not less than 4 001 units per quarter, 7½d. per unit; 5 001 units, 7d. per unit; 6 001 units, 6½d. per unit; 7 001 units, 6¼d. per unit; 8 001 units, 6d. per unit; 9 001 units, 5¾d. per unit; above 10 000 units, 5½d. per unit. The maximum demand rate is to remain as at present—9d. and 6d. per unit. Current for motor generators for cinematograph purposes is also to remain at 3½d. per unit.

Institution Notes.

Sir Charles Parsons has placed unreservedly at the disposal of the council of the BRITISH ASSOCIATION a gift of £10 000 5 per cent. War Loan stock. The total grants in aid of research made by the association since its formation in 1831 exceed £83 000.

Mr. B. Welbourn has been nominated chairman of the LIVERPOOL SUB-CENTRE of the North-Western Centre of the INSTITUTION OF ELECTRICAL ENGINEERS. Messrs. E. M. Hollingsworth and H. H. Harrison have been appointed vice-chairmen, and Mr. O. C. Waygood, hon. secretary.

The annual meeting of the ROYAL INSTITUTION was held on Monday, Sir James Reid, vice-president, in the chair. Fifty-seven new members were elected in 1921; sixty-three lectures and nineteen evening discourses were delivered; 651 volumes were added to the library during the year, including 210 presentation volumes. The following were elected officers for the ensuing year :—*President*, the Duke of Northumberland; *Treasurer*, Sir James Crichton-Browne; *Secretary*, Colonel E. H. Grove-Hills.

In connection with the DOMESTIC LABOUR-SAVING COMPETITION organised by the Women's Engineering Society, prizes have been awarded as follows :—*Section A* (engineering devices suitable for mechanical, electrical and automobile work, &c.) : Miss Ashberry, for dish-washing machine; *Section B* (structural improvements) : The assessors have decided not to award a prize in this section, as the designs did not reach a sufficiently high standard to warrant an award; *Section C* (any other labour-saving appliance for the home) : Miss Ramage, for "Ideal Oven." Two certificates of merit were also awarded in Section C : one to Mrs. Lockyer, for the "Hotlock and Coldlock," and one to Miss Long, for "Forty Plates in One."

Electric Traction.

NELSON (Lancs.) tramways were run at a loss of over £3 000 last year.

For the year ended Dec. 31 last, DARLINGTON TRAMWAYS DEPARTMENT shows a net loss of £2 364, against £3 166 in the previous year.

The accounts of ROCHDALE Tramway Department show that for the year ending March 31 last the tramways were run at a loss of £19 500.

LUTON Town Council has applied for an extension of time, until August 11, 1923, to complete the work authorised by the Tramways Order, 1905.

GLASGOW Tramways Committee are recommended by the Sub-committee on Extensions to offer £250 000 for the purchase of Paisley District Tramway Company.

As a result of a deputation from ratepayers to the EDINBURGH Tramway Committee, the electrification of the tramways on the Stockbridge route is to be started at once.

PRESTON Tramways Department report a decrease in the March returns, as compared with last year, of 110 857 passengers, and a decrease in the receipts of £638. A request from an advertising agency for permission to erect electrically-illuminated signs on the tramway standards has been refused.

In a report of the Birmingham Corporation Salvage Department just issued, the Committee state that the department has at present a FLEET OF THIRTY-FOUR ELECTRIC VEHICLES, and that it is intended to buy seven more. The vehicles are used in the collection of refuse under the continuous system in those districts which are considerable distances from depots, and which could only be worked on the continuous system by horses at greatly increased cost.

The SOUTH EASTERN & CHATHAM RAILWAYS COMMITTEE have agreed with the Trade Facilities Advisory Committee upon the general principles for raising the capital for their scheme for the electrification of the suburban sections of their lines. The capital, which will be guaranteed by the Government, will amount to about £6 000 000, and as authority to raise it can be obtained under the Electrification of Railways Powers Act, it is probable that the actual work will soon be commenced.

For the three months ended March 31, the receipts on the YORK tramways system have decreased £1 480, or an average of £114 per week, compared with last year. In order to reduce expenses the Tramways Committee have decided that on four routes the service shall be reduced from 7½ to 10 minutes on all days except Saturdays, during the morning hours between nine and noon. This will effect a saving in mileage of 20 373, in wages £320, and in current of £246 per annum. The maintenance charges will also be smaller, and the reduced staff will be utilised to work in place of men taking their annual holidays.

Personal and Appointments.

Major WILLIAM PAXMAN has been elected to succeed the late Mr. J. N. Paxman, as chairman of Davey, Paxman & Company.

Dr. W. E. S. TURNER, Prof. of Glass Technology at Sheffield University, has been elected President of the Society of Glass Technology.

Mr. A. H. DYKES (Handcock & Dykes) has been elected chairman of Beckenham Urban Council for the ensuing year, which office he held also in 1914.

The marriage took place in Chester last week of Mr. D. JENKINS (Swansea district manager for the Metropolitan Vickers Electrical Company) and Miss J. W. Thomas.

CARLISLE City Council has adopted the recommendation of the Finance Committee to reduce the salaries of the electrical engineer (Mr. C. W. Salt) and the assistant electrical engineer by 10 per cent., as from Oct. 1 next.

Mr. W. L. GRIFFITH has been appointed by the Canadian Government to succeed Sir George Perley as the Dominions representative on the Pacific Cable Board. Mr. Griffith is permanent secretary of the High Commissioner's Office.

Mr. HENRY H. OXLEY has recently resigned the position of London and District Manager to Mann, Egerton & Company with a view to organising and developing the sale of the Sims light and power plant. Before joining Mann, Egerton & Company Mr. Oxley was on the staff of Vickers, Limited, for some years.

Mr. C. I. BAKER, Superintendent of Blackpool Corporation Tramways, entered upon his duties as manager of the Ashton-under-Lyne tramways on Monday. Prior to his departure he was presented with a cheque by councillor H. Brooks, chairman of the Electricity and Tramways Committee, on behalf of the Electricity and Tramways Employees' Institute (which Mr. Baker was largely instrumental in establishing, and of which he has been secretary). He was also the recipient of an oak grandfather clock from the tramways employees.

The late Mr J. N. GREENALL, of Nottingham, managing director of Thomas Danks & Company, has left estate valued at £23 255 (net personality, £17 633).

Telegraph and Telephone Notes.

The new underground trunk telephone service between MANCHESTER AND LONDON was opened for commercial use last week. One of the chief features of the new line is the adaptation of the thermionic valve amplifier. We recently gave particulars of the construction of this line.

Four AUTOMATIC TELEPHONE CALL BOXES have been installed at Charing Cross Railway Station, and five at the Bank. The method of procedure with the new instruments is that, instead of waiting for the operator to connect the caller with the number desired before the pennies are placed in the box, the pennies are inserted before connection is obtained. The insertion of the pennies causes the operator's lamp to glow, and she then inquires what number is required. Should the caller desire to cancel the call, he may depress a button labelled "B" and his money will be returned. Should the call proceed, the caller will hear the subscriber at the other end give the usual signal "Hello," but he will be unable to make himself heard until he has depressed button "A." The caller does this immediately on hearing "Hello," which depression transfers the pennies deposited into another channel, completing the circuit and enabling subscriber and caller to carry on as usual.

Wireless Notes.

The SWISS MARCONI WIRELESS STATION was formally opened at Munchen Buchseo, near Berne, on the 26th ult.

The NORTH ESSEX WIRELESS SOCIETY, of which Mr. H. E. Adshead is president, and Mr. F. T. Smith, Rutlands. Felstead, is hon. sec. and treasurer, hold weekly meetings at 15, Rayne-road, Braintree, for discussion of wireless topics.

The TORONTO correspondent of the "Manchester Guardian" states that the radio fever has spread from the United States to Canada, and all the electrical firms, and even other organisations not closely associated with electrical apparatus, are experiencing an extraordinary inflation of trade. Factories are running under pressure, with three shifts every twenty-four hours, under conditions similar to those prevailing in munition works in the urgent days of the war.

The INTERNATIONAL WIRELESS CONFERENCE, composed of representatives of the Radio Corporation of America, Compagnie Generale de Telegraphie sans Fil, Gesellschaft fur Drahtlose Telegraphie m.b.h., and Marconi's Wireless Telegraph Company, completed its sittings last week. A number of important questions dealing with the development in different parts of the world of wireless telegraphic and telephonic communication have been considered and satisfactorily settled. As a result of the agreement between the four companies a number of new international wireless telegraph services are to be opened in the early future. In order that commercial wireless telegraphy and telephony should be developed to the best advantage in the interests of the public and of international commerce, it has been decided that the companies should not erect any stations which would entail the harmful radiation outside an agreed radius of harmonics or secondary waves which are beyond the definite wavebands allotted to each particular station.

Business Items, &c.

WILKINSON BROS., electricians, of Eldon-street, Barnsley, have recently opened new showrooms at 15, The Arcade, Market-hill, Barnsley.

Mr. G. LOCK, late of the Surbiton Electric Company, has commenced business as an electrical engineer at 164, Thornhill-road, Tolworth, Surbiton.

ARTHUR JONES & COMPANY, of 15, Dock-street, Middlesbrough, have been appointed sub-agents for Middlesbrough and Teeside under the Simplex and Credenda joint sales service.

GREEN & SMITH, LTD., electrical engineers and contractors, Albert Works, Meadow-lane, Leeds, have been appointed sole agents in the West Riding of Yorkshire for Greenwood & Batley, Ltd., Leeds, a.c. and d.c. motors, dynamos, and alternators, and are open to receive inquiries for complete electric light and power plants, also a.c. and d.c. motors, dynamos, and switchgear.

JOHN M. HENDERSON & COMPANY announce that they have made arrangements with Mr. F. G. Mitchell, of The Mitchell Conveyor & Transporter Company, contracting engineers, Atlantic House, 45-50, Holborn-viaduct, London, E.C. 1, to undertake the manufacture of Krom crushers, Maxecon mills, and new-type Kent mills for that company. They have also acquired joint selling rights of these machines.

It is announced that the UNITED STATES GOVERNMENT have withdrawn their action against the Postal Telegraph Company for the recovery of £500 000 alleged to have been advanced to the Postal Telegraph Company during the period of Federal control of telegraph communications. The company, as well as the Commercial Cable Company, are subsidiaries of the Mackay Companies, who were strong opponents of Mr. Burleson's effort to take over the control of cable communications.

Imperial Notes.

The SHAWINIGAN WATER & POWER COMPANY has increased its capital from $20 000 000 to $40 000 000.

ST. GEORGE (N.S.W.) County Council has in course of erection generating plant for supplying current to the towns of Hogarth, Bexley, Rockdale, and Hurstville.

In the report of the NEW BRUNSWICK ELECTRIC POWER COMMISSION for 1921 it is stated that there are undeveloped water power resources in the Province capable of yielding 200 000 H.P. continuously. Apart from the Grand Falls, estimated at 90 000 H.P., the various falls vary from 1 000 to 10 000 H.P.

The AUSTRALIAN POSTMASTER-GENERAL recently informed a Sydney deputation, who complained of the INEFFICIENT TELEPHONE SERVICE, that this was due to the inadequacy of the sums voted by Parliament for the service, and the delay caused by having to wait for Parliamentary sanction to orders for materials. To bring the service up to date would require £9 000 000.

The accounts of the ADELAIDE (S. AUSTRALIA) MUNICIPAL TRAMWAYS TRUST for the half-year ended January 31 show revenue £288 696, operating expenses £206 249, and net surplus of £3 569, after providing for instalment of loans, interest, &c. The Trust is unanimously in favour of early connection of the Port Adelaide system to the Adelaide lines in order to reduce the loss on the former. Fifty additional cars were on order at the time the report was issued, and plans were being prepared for various extensions of tramways under the control of the Trust.

Foreign Notes.

An electrical crematorium has been opened in OSAKA.

The Griesheim Electron Chemical Works, GERMANY, are selling, it is stated, some of their patents to United States interests.

It is announced that a German firm has secured a contract for rebuilding PETROGRAD, including the restoration of the tramways of the city.

The CHINESE MINISTRY of Communications has decided to install a long distance telephone between Nanking, Chinkiang, Yangchow, Kiangying, and Shanghai. The material for this work will be supplied by the Japanese branch of the Western Electric Company of New York through its agents, the China Electric Company, Ltd., of Shanghai.

A Commission has been appointed by the DUTCH GOVERNMENT to examine a scheme for erecting five large power stations, which are to be linked up by a 50 000 V cable. One station will be in Amsterdam, one in Rotterdam, one in Dutch Brabant, and another in the Dutch coal-mine area. The situation for the fifth station has not yet been chosen.

The water power at St. Martin de Landres, HÉRAULT (France), is being developed by an agricultural co-operative society in order to provide electricity in thirty-seven communes. The projected station will be able to supply 1 500 H.P. for eight months, and for the remainder of the year at least 500 H.P. The necessary capital (three million francs) will be provided by members of the society, and electric current will be used for light, power, and domestic purposes.

Miscellaneous.

A NEW X-RAY APPARATUS was formally opened at Clayton Hospital, Wakefield, on Monday by Sir Edward Brotherton, by whom it has been presented.

The India Rubber, Gutta Percha & Telegraph Works Company have been awarded the first prize (£1 400) in the Air Ministry competition for SAFETY FUEL TANKS FOR AIRCRAFT.

Prof. ALEXANDER HORNE has notified his intention to resign on June 30 from the Chair of Engineering at Robert Gordon's Technical College, Aberdeen, having been appointed head of the Polytechnic School for Engineering, London.

A complaint has been made that OPTICAL AND SCIENTIFIC INSTRUMENTS manufactured in Germany are being sold in the United Kingdom at prices below those at which British goods can be profitably manufactured, and the Board of Trade have referred the matter to a committee to consider the question of the imposition of a duty under Part II. of the Safeguarding of Industries Act on such German goods. The committee will hear evidence on May 15.

Obituary.

The death occurred at Leigh-on-Sea on April 22 of Mr. JAMES F. CLUNAS, who for the last four years had been attached to the staff of Vickers, Ltd., in their electrical, and latterly in the hydro-electric, department. Mr. Clunas was trained and started his engineering career in the works of Bruce, Peebles & Company, and subsequently served in the London office of that firm. Previous to the outbreak of War, he had been a number of years in the office of Tozer, Kemsley & Millburn, whose service he left to volunteer for Service. He served in the Royal Naval Volunteers Signal Division, having gone through the Gallipoli Campaign from the second day until the withdrawal, and afterwards served a year and a-half in Flanders, when he was invalided out of the Army, owing to an accident. Mr. Clunas' cheerful, straightforward, and conscientious disposition had gained him a wide circle of friends, who will be grieved to hear of his sudden death.

Possible Trade Openings.

A WESTERN CANADIAN FIRM of wholesalers and distributors of electrical supplies desire to get in touch with United Kingdom manufacturers of radio-telephone apparatus and supplies, including tubes and bulbs.

A firm of machinery merchants and agents in Christchurch, with connections throughout the DOMINION OF NEW ZEALAND, desire to receive catalogues from manufacturers of engineers' supplies (mechanical and electrical), motor accessories, &c. The firm, who have shipping agents on this side, specially desire the catalogues of manufacturers who exhibited at the recent British Industries Fairs. Particulars can be obtained from the Department of Overseas Trade (Ref. No. 462).

H.M. Vice-Consul at St. Vincent, CAPE VERDÈ ISLANDS, reports that a local firm, which has secured the concession for lighting the town with electricity, is anxious to obtain an agency for a United Kingdom manufacturer of electric lighting house fixtures (switches, lamp sockets, reflectors, insulated wire, &c.), and for incandescent electric lamp bulbs of 200, 100, 32, and 20 c.p. The firm also require quotations for fixtures for electric (incandescent) street lamps. Applications for name and address must be sent to the Department of Overseas Trade (Ref. No. 475).

H.M. Trade Commissioner at WINNIPEG (Mr. L. B. Beale) has recently been consulted by a Western Canadian company, regarding the supply of transformers. Mr. Beale states that the general type in use throughout Western Canada is a single-phase service transformer, pole type, 60 cycle, 2 200 to 110/220 V. The prices in all cases quoted for these transformers include cut-outs and hangers. For the guidance of United Kingdom firms he has secured from the Winnipeg Hydro-Electric System details of tenders received during the past month for all sizes of transformers (single and three-phase). He has also forwarded to the Department of Overseas Trade, from whom further paticulars may be obtained, a rough sketch of the type of transformer that is in use in Western Canada.

Openings for Trade in the Netherlands.

Extracts from the Dutch press of recent dates include the following, which may lead to openings for British trade :—

The N.V. Provinciale Utrechtsche Electriciteits Mij. (Provincial Electric Supply Company of Utrecht), of 32, Catharijnesingel, Utrecht, are preparing plans, in co-operation with the management of the municipal electric works and tramways (Nicolaas Beetsstraat 3, Utrecht), for the building of a large provincial ELECTRIC POWER STATION NEAR UTRECHT.

Proposals have been put before Rotterdam Town Council to extend the telephone exchange by an additional building with a capacity of 20 000 numbers. Estimate Gld. 450 000. It is also proposed to build an additional electric power station, which will probably have three generating sets of 1 500 kW each. Estimate, Gld. 600 000.

In connection with works to be carried out in the Prise d'Eau, of the Dune Waterworks, and at the pumping station, "Leiduin," proposals have been put before the Town Council of Amsterdam for the erection of a pumping station and the adoption of electrically-driven pumps at the stations on the Westerkanaal and the Barnaart-Schusterkanaal; the laying down of a l.t. cable and of the necessary telephone communication; the erection and equipment of a transformer sub-station in the pumping station at the Barnaart-Schusterkanaal; the erection of a steam dynamo with condensing plant for the existing Laval steam turbine at the pumping station, "Leiduin."

Catalogues, Price Lists, &c.

An illustrated pamphlet, entitled MODERN WELDING METHODS, has been issued by Mr. C. L. Jones. Many patents covering improvements in welding methods and welding material have been filed by Mr. Jones, to whom also is said to be due the discovery of how to weld effectively alloy metals by the use of metal electrodes which will produce in the weld metal of the same composition as the metal welded. The illustrations show work being carried on in Mr. Jones's welding shops at Islington.

Great strides have been made since the war by FULLERS' UNITED ELECTRIC WORKS, LTD., in the manufacture of their "Ebonite" mouldings, and the firm state that they consider they are now equipped to compete with Continental manufacturers in most of the mouldings of which these firms held the monopoly. List No. 150 A, recently published, illustrates the variety of mouldings the company now manufacture, and includes telephone components, insulators, motor-car radiator caps, knobs, lead conduits, steering wheels, accumulator lids, stoppers, separators and grids, also containers for accumulators.

Two excellently produced and fully illustrated publications are to hand from METROPOLITAN-VICKERS ELECTRICAL COMPANY. Publication No. 7 874/2, entitled "Power in the Textile Mill," deals with both electrical and mechanical drive, and the illustrations show typical examples of installations carried out by the firm in this country, including electrical installations at the Premier Mills Company, Stalybridge; James Halliwell's Townsfield Mills, Darwen; Peel Mills, Bury; T. Ashton Harrison & Company; John Haigh & Sons, Huddersfield; Joshua Hoyle & Sons, Summerseat. Publication 7 840/2, "The Electrical Drive and Control of Machine Tools," embodies the results of the firm's investigations in regard to the individual electrical drive and control of machine tools, which for tools requiring approximately 5 H.P. or above has, they claim, an overwhelming advantage over the group system.

Companies' Meetings, Reports, &c.

British Electric Transformer Company.

The nineteenth ordinary general meeting of this company was held at Winchester House, E.C., on Tuesday, May 2, Mr. A. F. Berry (the chairman) presiding.

In moving the adoption of the report and accounts, the chairman compared the items in the accounts with those of the previous year, the principal point being the addition of £47 000 to the freehold land, buildings, plant, machinery account, &c., the bulk of which represented new plant and machinery installed during the past year. The loan on mortgage and interest accrued, amounting to £31,851, had disappeared from the balance sheet as being paid off in full. Of the available cash, £68 536 had been invested, and such investments had since been sold, the money realised being reinvested as opportunity afforded, so that it could be readily used when required for manufacturing purposes. The general charges on profit and loss account were £10 500 more than the previous year, but gross profit on trading had increased by £40 000 and net profit by over £21 000. Out of the available balance of £97 594 they were able to pay for the fourth year in succession a dividend of 10 per cent., plus 2½ per cent. bonus, and to carry forward £12 708. This was the nineteenth annual meeting, and none of the previous years had shown anything so good.

A Difficult Period.

Continuing, the chairman said: We have been, and are going, through times of such difficulty of late, that I cannot help feeling that the time may not be distant when the strong confidence of the shareholders will be needed to help us tide over the one or more years during which it may be impossible to produce the splendid results to which we are by now accustomed and therefore expect. To-day it would have been pleasant to say nothing but those things that please.

We have, however, at the annual general meeting, always endeavoured to give to the shareholders as much information as we could, and where it has been in any way possible to forecast results we have endeavoured to do so. You may remember that last year we started with 50 per cent. more work in hand (in money value, or 30 per cent. more in horse power) than we had at the beginning of 1920. This year we started with roughly 60 per cent. *less* work in hand (calculated in horse power, it would be still *worse* in money value) than we had at the beginning of 1921. This work in hand will not carry with it the same ratio of profit which we looked forward to at our last year's meeting. The difficulties due to this shortage of work, magnified as they are by strikes and lock-out troubles, cannot be overlooked.

Some Signs of Improvement.

Last year I ventured the opinion that "The next few years will test the capacity of even the best captains of industry." Some of us hoped that adversity would bring the different interest in the ranks of industry rather closer together, but we all know this is a state of affairs to be wished for and worked for rather than one accomplished. It appears to me that the active minorities, whose business or avowed intention it is to make trouble between the different members of the various British industries' teams, are having their own way far too much, and I fear that industry will not prosper as we desire until its natural leaders are actually encouraged to lead. You are well aware that the Stock Exchange, which usually bases its opinions and judgment upon the ideas of those best able to advise it, are indicating in no uncertain way their belief in a return of comparatively good times.

There are signs, too, in the heavier industries of some improvement, but I shall be agreeably surprised if the return of prosperity will be sufficient to enable ordinary dividends of any appreciable value to be obtained, at any rate, for the next year. These extremely bad times through which we are passing can be made to have their uses, and in a company such as ours there is very much to do in the way of staff work and co-ordination of effort with other sections of the industry. It is only by a continuance and even an improvement on the efforts of office and factory staff that we shall fit ourselves to play our full part in those better times which somewhere ahead we are steering and working for.

The Result of Prudent Planning.

Few of the shareholders outside this company realise what an effort it has been to achieve the results shown. They are the result of a carefully thought out policy carried out loyally and efficiently in the main by office and works staff, and it is a pleasure once more to be able to thank all those who have pulled their full weight during the past year and enabled us to accomplish what we have done. Some of you may be shareholders in concerns which are considered less fortunate than ourselves. I may tell you that unless our plans had been laid long ago with the greatest prudence and carried out with persistent care, we might, even during this past year, have found ourselves with a heavy loss instead of record profits. I do not mention these facts in any boastful spirit, but I wish shareholders to appreciate the position and times through which we are passing.

Once again it is my pleasure, on behalf of the board to thank not only those of the company's employees who have done their best in the company's interests during the past year, but also those shareholders who do their utmost to make it possible for themselves and their fellow shareholders, including those who work in office and factory, to derive the greatest advantage from this company by taking an intelligent interest in its products. On the other hand, it sometimes surprises me how little many of our shareholders do to further their own general and particular interest in this company, in spite of my requests made from year to year that they should take an interest *in* their company's products if they desire to take the maximum interest *out*. The real and ascertained value of what *is* done by the comparatively few gives a very clear indication of what great benefits to themselves and the company would result from individual interest and action by the many. For instance, shareholders might well go into electrical shops of all descriptions and ask about "Tricity" goods—"'Tricity' as Advertised"—"How it can help ME—Where—Why—and to what extent." Such action on your part may appear small to you, but please think of its effect taken with that of thousands of others in and out of this company. The report and accounts were adopted unanimously.

Indo-European Telegraph Company.

Presiding last week at the annual meeting of the Indo-European Telegraph Company, Mr. J. Herbert Tritton said that they were still without the necessary information from other administrations to enable them to close the books for 1921. The investments continued to show an appreciation, while, having regard to actual political developments, the position of the Russian assets might be regarded in a somewhat more favourable light; the directors were therefore of opinion that any drastic step, such as writing off, need not at the moment be taken. With regard to the final dividend for 1921, the equalisation of dividends fund was, as the shareholders were informed at the last meeting, now exhausted, and the total dividend for 1921 was, therefore, restricted to 7 per cent. The directors had at last good news to communicate. The Polish concession was signed some time back. Within the last few days they had been advised by the Russian Department of Posts and Telegraphs that their concession from the Moscow Government was signed on April 12. This was a very important fact, as the concession covered the whole territory traversed by their line from the Polish frontier on the west to the Persian frontier on the east, transiting various Federated States, who had also approved the concession. Their concession from Persia was already in existence, and that from the German Government, although not actually signed, owing to international politics, had for a long time been agreed in principle, and should offer no difficulty.

The condition of the company's line was more satisfactory than had been expected. They were informed from a reliable source that the line was workable for a stretch of over 200 miles north-west of Odessa, while east of Odessa a similar state of affairs existed for 300 miles into the Crimea. Beyond the Straits of Kertch the line was in working order between Ekaterinodar and Tiflis. Between Tiflis and Erivan there was a short section where the repairs had not yet been completed. The section Erivan-Djoulfa, on the Russo-Persian frontier, had undergone repair, and was now in working order, as was also the company's Persian section, Djoulfa to Teheran. The Black Sea cable, Odessa-Constantinople, was again in working order, and, they understood, had already been officially opened by the Soviet Government representatives at Odessa. This cable would, therefore, shortly be able again to carry the classes of traffic formerly dealt with by it, and would, they hoped, help to re-establish business relations generally with Southern Russia and the Black Sea ports. They were also informed by the Indo-European telegraph department that their Persian lines were in good order. The most arduous part of their work was undoubtedly the section from the German and Polish frontier on the west to the Polish-Russian frontier on the east. Much of their line in that territory had absolutely disappeared as a separate international line, and where three or four wires were suspended there were now ten to twenty of all sorts, including telephone wires; they, therefore, in accord with the Polish Government, arrived at the conclusion that their line must be rebuilt in a new location—namely, along the great *chaussées*, or high roads. The directors hoped before long to be able to announce that the Indo route was once more carrying international traffic, after being totally interrupted since July 31, 1914.

National Electric Construction Company.

In moving the adoption of the report and accounts at the annual meeting of the National Electric Construction Company last week, Mr. G. H. Nisbett (the chairman) said that the year's working had again shown an improvement, and the balance of profit amounted to £9 681, compared with £6 726 in 1920. Adding the balance of £8 538 brought forward, there was a total available of £18 219. It was proposed to write off £1 000 from the sum of £4 510, at which the free-wired installations appeared in the books, to start a general reserve fund with the sum of £3 000, and to provide a similar sum for a reserve for equalisation of dividends, with a view to providing as far as possible for the payment of a steady dividend in spite of the fluctuations which were inevitable with a trading company. It was further proposed that £1 300 should be added to the reserve on the Dewsbury and Ossett Tramways, thus providing a total reserve for renewals of £2 000. A dividend of 6 per cent. on the ordinary capital was recommended, leaving £4 819 to be carried forward. The Debenture Redemption Fund stood at £25 090, as compared with £21 700 the year before. The overdraft at the bank was £7 997 at the date of the balance-sheet, as compared with £12 003, but they had now a balance to their credit of over £4 000. Contracts in course of completion (less payments on account) were only £1 736, as compared with £12 106 last year, but they had reason to think that some further business of value would shortly be in hand. The expenditure on the Wisbech Electric Light & Power Company still continued. This concern was doing very well, and it followed that with a light and power company the better it did the more the capital expenditure increased for the provision of additional plant, mains, and services.

The directors of the City of Buenos Ayres Tramways Company (1904) have declared a dividend of 1s. 3d. per share (5 per cent. per annum), less tax, for three months ended March 31.

Chagford and Devon Electric Light Company are offering for public subscription £8 000 7½ per cent. guaranteed first mortgage debentures in 1 600 debentures of £5 each at par, and 5 000 9 per cent. cumulative preference shares of £1 each at par.

Mexboro' & Swinton Tramways Company announce a dividend of 2½ per cent., tax free, for the year. The sum of £2 000 has been placed to reserve renewal account, £245 written off for plant, &c., £500 for income tax, leaving £246 to be carried forward.

The sum of £3 064 on account of the sinking fund of the British Columbia Electric Railway Company's Vancouver Power Debentures, 1923, and first mortgage debentures is held by the British Empire Trust Company, who are prepared to receive offers for sale of the debentures up to May 22.

The directors of the Great Northern Telegraph Company of Denmark recommend a total dividend and bonus of 22 per cent. for 1921, including 5 per cent. already paid. The sum of £33 333 has been set aside for reserve and renewal, £55 555 for pensions, and £222 222 for extraordinary taxes, leaving £302 679 to be carried forward.

The scheme of arrangement (Electrician, April 28), considered last week at the meeting of the eight per cent. ten-year noteholders and shareholders of the Southern Brazil Electric Company, was unanimously adopted. The meeting of the six per cent. mortgage debenture holders was adjourned to next week in the absence of the necessary quorum.

The income of the Direct United States Cable Company for the year ended March 31, 1922, amounted to £45 224, plus £4 265 brought in, making a total of £49 489. After providing for income tax, directors' fees and administration expenses, a balance remained of £37 913, out of which the directors have paid a dividend of 4 per cent. for the year, carrying forward £3 916.

The net profit of Craigpark Electric Cable Company for the year ended March 31 was £12 054, after making provision for corporation tax, making, with £2 160 brought in, £14 214. The directors recommend that £2 000 be placed to depreciation of machinery, &c., £2 000 to reserve, and that a dividend be paid on 37 500 ordinary shares at the rate of 12½ per cent. for the year, leaving £2 676 to be carried forward, subject to directors' fees.

The net profit of the International Lighting Association for 1921 was £1 046, making, with the balance brought in, less dividend on the ordinary shares and directors' fees, £1 815. After payment of a dividend on the preference shares at the rate of 5 per cent. for the year, the balance of profit was £1 042, which the directors recommend be carried forward, subject to directors' fees. The report states that the dividend on the 6 per cent. cumulative preference shares of the Para Electric Railways & Lighting Company is in arrear from November 30, 1920.

In moving the adoption of the report and accounts at the annual meeting of the City of Santos Improvements Company, last week, Mr. N. B. Dickson said that the progressive results of the company's operations for the last two years had not been maintained owing to the acute depression, both financial and commercial, which had existed in Brazil. The approximate trade returns for 1921, however, indicated that the adverse trade balance of the country would be about £1 800 000, against £17 000 000 in 1920. That implied some improvement in the financial situation, and they might be justified in hoping that during the current year a favourable trade balance would be secured. An abstract of the accounts appeared in our issue of April 21.

The accounts of the Radio Corporation of America for 1921 show gross income from transoceanic communications $2 138 626; gross sales, $1 468 920; from marine service, $553 298; making a total of $4 160 844. After deducting general operating and administration expenses, depreciation of plant and cost of sales ($3 762 231), a balance of $398 613 remained, making, with other income, $426 800, applied against amortisation of patents. No dividend was paid during the year on either the preferred or the common stock outstanding. The report states that the current liabilities have been reduced by about $930 000, and that current assets exceed current liabilities by nearly $4 000 000. During the year $3 000 000 was spent in extending plant and equipment, investments in which now total $12 702 086. Reserves for depreciation and obsolescence of plant and amortisation of patents amount to $2 318 135.

The accounts for the year ended December 31, 1921, of the Madras Electric Tramways (1904), Ltd., show a gross profit of £34 661. After debiting interest and London office expenses, making provision for the debenture stock sinking fund, and transferring £10 000 to depreciation and renewal account, there remains a balance of £9 744. To this has to be added the sum of £5 556 brought forward from last year, making a total of £15 299. From this sum is deducted dividends on the preference shares paid, less income tax, on September 30, 1921, and March 31, 1922, amounting to £6 000, leaving a balance of £9 299. The directors recommend the payment of a dividend on the ordinary shares of 5 per cent. for the year, free of income tax (£2 863), leaving £6 436 to be carried to next year's accounts. The traffic receipts and running expenses in rupees show decreases of 15·5 per cent. and 10·5 per cent. respectively on 1920. Repairs and maintenance have been debited to revenue, and special improvements and renewals to "depreciation and renewal account," as usual The debenture stock sinking fund now amounts to £13 691.

Tenders Invited and Accepted.

UNITED KINGDOM.

Eccles Town Council. May 8.—Supply and erection of overhead distributing mains for 200 houses. Particulars from the Borough Electrical Engineer, Cawdor-street, Patricroft.

Mountain Ash Urban Council. May 8.—Extra high-tension overhead and underground transmission mains. Specification from the Electrical Engineer.

Bradford Corporation. May 9.—Wiring and fitting 120 houses, comprised in the municipal housing schemes. Specification from the City Architect, Town Hall, Bradford.

Fleetwood Urban Council. May 9.—One 1 000 kW d.c. turbo set, with switchgear and condenser. Specification from the Engineer and Manager, Electricity Works, Fleetwood.

Great Western Railway. May 15.—Supply for three or six months from June 1 of (18) telegraph instruments, (19) electrical apparatus (insulators), &c., (21) telegraph ironworks and tools, (22) telegraph drysalteries, (24) electric lamps. Samples and patterns may be seen and tender forms obtained on application at the office of the Stores Superintendent, Swindon.

Rathmines and Rathgar Urban Council. May 15.—Two 200 kW converting sets, with high and low tension switchgear, cable connections, &c. Specification can be obtained at the Electricity Works.

Edinburgh Corporation. May 15.—Six or twelve months' supply of electricity meters. Particulars from the Engineer and Manager, Electricity Department, Dewar-place, Edinburgh.

Edinburgh Corporation. May 16.—1 180 tons steel tram rails, 45 tons fishplates, 110 tramcar trucks, 110 trolley standards, and one electric welding plant.—Specifications, &c., from the Tramways Manager, 2, St. James's-square, Edinburgh.

High Commissioner of India. May 26.—Insulator cups, porcelain or glass. Particulars from Director-General, India Store Department, Belvedere-road, Lambeth, S.E. 1.

Stepney Electricity Department. June 8.—Manufacture, supply and erection complete of (*a*) three water-tube boilers, together with chimneys, economisers and other accessories; (*b*) two 10 000 kW turbo-alternators with condensers, accessories and switchgear. Particulars from Mr Wm. C. P. Tapper, Borough Electrical Engineer and Manager, 27, Osborn-street, Whitechapel, E. 1.

Hackney Electricity Department. June 14.—Pipework and valves. Particulars from the Borough Electrical Engineer, 306, Mare-street, Hackney, E. 8.

Kingston-upon-Hull City Council.—Automatic telephone exchange for Hessle. Particulars from Mr. T. Holme, Mytongate, Hull.

Powell Duffryn Steam Coal Company.—Six months' supply of copper wire and electrical accessories. Forms of tender, &c., from the Stores Manager, Aberaman Offices, Aberdare.

AUSTRALIA.

Department of Public Works, New South Wales. May 29.—*Supply, delivery and erection at the State power-house station, Uhr's Point, Sydney, together with the testing and maintenance thereof for a period of three months, of one 1 000 kW steam turbo-generator, complete with all fittings and accessories.

Cheadle and Gatley Urban Council has accepted the tender of the Macintosh Cable Company, for cables for the electricity scheme, at £18 736 17s. 9d.

Ventnor Urban Council has accepted the offer of the Isle of Wight Electric Light & Power Company for street lighting for three years for a quarterly payment of £68 15s., plus 6d. per unit for current consumed.

London County Council have accepted the tender of Emerson Bros. (lowest tender received) for the installation of electric lighting and fire alarms at the Intermediate Schools, Swaffield-road, Wandsworth, at £366 12s. Forty-seven tenders were received, the highest being £1 148 15s.

Sunderland Corporation have accepted the following tenders: British Insulated & Helsby Cables, Ltd., 600 yards 0·15 four-core cable; Callender's Cable & Construction Company, service boxes and link boxes; Armstrong, Addison & Company, capping; Ferguson, Pailin, Ltd., low-pressure switch panels: Cambridge & Paul Scientific Instrument Company, temperature and flue-gas recorders; Consolidated Pneumatic Tool Company, electric drilling machine.

Books Received.

"Electricity." By Sydney G. Starling, A.R.C.Sc., B.Sc., F.Inst.P. (London: Longmans, Green & Company.) Pp. viii.+245. 10s. 6d. net.

"A Course in Electrical Engineering." Vol. II., Alternating Currents. By Chester L. Dawes, S.B. (London: McGraw Hill Book Company, Inc.) Pp. xiv.+526. 20s. net.

County Court Judgments.

[Note.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

BARRACLOUGH, W., Ridgemont, Wyke, electrical engineer. £15 7s. 7d. Mar. 3.

BURROWS, Frederick, 52, Victoria-road, Clapham Common, electrician. £15 3s. Feb. 20.

HURLINGHAM ELECTRIC COMPANY, 28, New King's-road, Fulham, electricians. £11 11s.. Feb. 28.

MARCUS, C. A., 212, High-road, Willesden-green, electrical engineer. £17 0s. 1d. Feb. 24.

PERRIN, Francis Leopold, 5 and 7, College-street, Northampton, electrical engineer. £47 2s. 5d. Mar. 1.

SMART, Mr. W. N., Cross-street, Oldham, electrical engineer. £32 17s. 7d. Mar. 4.

SOHO ELECTRICAL WORKS, 6, Soho-street, Islington, Liverpool, electrical engineers. £19 1s. 3d. Feb. 28

SPRINGER, Robert, 253, Plymouth-green, Manchester, electrical engineer. £44 9s. 10d. Mar. 1.

Deed of Arrangement.

GRIFFITH, Benjamin, trading as EXCEL ELECTRIC COMPANY, 30, South Castle-street, Liverpool. In this matter (see our last week's issue) the following are creditors:—Siemens Bros. & Company, Ltd., London, £68; Newman Electric Company, London, £32; Baxendale Bros., Ltd., Liverpool, £946; Moore & Barker, Ltd., Liverpool, £63; British Thomson-Houston Company, Liverpool, £32; General Electric Company, Liverpool, £41; Woolliscroft, J. H., & Company, Liverpool, £18; Downes & Davies, Liverpool, £15; Buying, G., Liverpool, £15; Burns, D., Liverpool, £200; Thomas, F. G., Liverpool, £80; Ward & Goldstone, Ltd., Salford, £22.

Mortgages and Charges on Limited Companies.

[Note.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

LLANGEFNI ELECTRIC LIGHT & POWER COMPANY, LTD. Registered April 20, transfer of mortgage securing £700, to bank, charged on power station and electric light works, Mill-street, Llangefni. *£2 400. Jan. 14, 1921.

NEWCASTLE & DISTRICT ELECTRIC LIGHTING COMPANY, LTD. Registered April 15, debentures dated March 27, 1922, securing £10 000 and further sums not exceeding in all £20 000; general charge. *£301 180. April 7, 1922.

OMEGA LAMPWORKS, LTD., London, S.W. Registered April 18, £1 000 debentures; general charge. *£1 000. December 27, 1920.

WILKINSON (THOMAS) (ARNSIDE), LTD., electrical engineers. Registered April 18, £10 250 debentures and mortgage collateral thereto, to bank; general charge and land and works at Arnside. *Nil. May 14, 1921.

Satisfactions.

ELECTRIC CONSTRUCTION COMPANY, LTD., London, E.C. Satisfaction registered April 19, £47 200, part of amount outstanding July 1, 1908.

Private Meetings.

[*Inclusion under this heading does not necessarily imply failure. Many private meetings are called merely for the purpose of the debtor consulting his creditors as to his position when he may not be insolvent.*]

HUBERT D. CARTER (BANGOR), LTD. (in voluntary liquidation), electrical merchants, &c., Bangor. The statement of affairs presented at the statutory meeting of creditors showed ranking liabilities of £2,073. The indebtedness to the trade was £1 035. Assets were estimated to realise £617, or a deficiency as regarded the creditors of £1 456. The company was registered in February, 1920, when it took over an existing business as a going concern. The company was to act as a distributing agency for another concern on a 10 per cent. basis. The purchase price paid by the company was £2 500, practically all of which was satisfied by the allotment of fully-paid shares. A petition has been presented for the compulsory winding-up of the company, but it was stated at the meeting that if the voluntary liquidation was continued Mr. Carter would withdraw his claim for £794. Several creditors expressed the opinion that it would not be advantageous for compulsory liquidation to take place, and a resolution was passed confirming the voluntary liquidation with G. G. Poppleton, of Poppleton & Appleby, Birmingham, as joint liquidator.

WATTS, WILLIAMS & COMPANY, LTD. (in voluntary liquidation), electrical engineers, Leysfield-road Works, Goldhawk-road, Shepherd's Bush, London, W. At a meeting of creditors, held recently, a statement of affairs was submitted which showed ranking liabilities of £25 607, against assets estimated to realise £11 027. After allowing £198 for preferential claims, the assets were estimated to realise £10 829, or a deficiency of £14 778. The company was registered in April, 1920, with a nominal capital of £60 000, and shares to the value of £35 700 were issued for cash. A further 5 000 shares of £1 each were issued as fully paid to the British Generator Company, Ltd., as consideration for assets transferred. The company had manufactured lighting sets, but had experienced great difficulty in perfecting them, while the sole selling agents recently went into voluntary liquidation owing Watts, Williams & Company, Ltd., £2 200, of which nothing had yet been paid. The company had also carried on a welding business and repair shops. During the year ended March 31, 1921, there was a loss on the trading of £8 350, while since that date there had been further losses aggregating £16 000. Owing to the heavy losses the directors and their friends had advanced substantial sums to enable the company to continue, and they were now cash creditors for rather more than £18 000. The creditors decided to confirm the voluntary liquidation of the company, with Mr. F. J. Carpenter, of W. B. Keen & Company, C.A., 23, Queen Victoria-street, E.C., as liquidator.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Companies Winding-up Voluntarily.

BRITISH GENERATOR COMPANY, LTD. F. J. Carpenter, of W. B. Keen & Company, 23, Queen Victoria-street, London, E.C., appointed liquidator. Meeting of creditors at the offices of the liquidator on Monday, May 8, at 3 p.m. Particulars of claims to the liquidator by May 27.

STANTON & COMPANY, LTD., electrical and general engineers, Albert-road, Hinckley, Leicestershire (in voluntary liquidation). Meeting of creditors at the offices of Watson & Meller, 29, Friar-lane, Leicester, Monday, May 8, at 3 p.m. Particulars of claims to the liquidator by May 24.

Bankruptcy Information.

MAYNER, Robert Victor, 62, Harris-street, Peterborough, late Narrow-street and Wentworth-street, Peterborough, electrical engineer. First meeting, May 9, 12.15 p.m. Public examination, June 9, 10.30 a.m., Law Courts, Peterborough.

MORRISON, Roy Thomas, 82, Lumb-lane, Bradford, electrical enigneering contractor. First meeting, May 6, 10 a.m., 12, Duke-street, Bradford. Public examination, May 24, 10 a.m., County Court, Manor-row, Bradford.

ORMONDE, Frank Sinclair, in co-partnership with another under the style of the SOHO ELECTRICAL WORKS, 125, Islington, Liverpool, electrician. First meeting, May 11, 11 a.m., 11, Dale-street, Liverpool. Public examination, May 30, 10.30 a.m., Court House, Government Buildings, Victoria-street, Liverpool.

RIMMER, W. F. (male), 21, Ellesmere-street, Patricroft, Lancashire, electrical engineer. Receiving order, April 28. Creditor's petition.

THREAPLETON, William Walton, Thornbury-drive, Bradford, electrical, &c., engineer. Receiving order, April 26. Debtor's petition. First meeting, May 10, 10.30 a.m., 12, Duke-street, Bradford. Public examination, May 24, 10 a.m., County Court, Manor-row, Bradford.

Edinburgh Gazette.

LIVINGSTONE & MALCOLM, electricians, 7, Canal-street, Coatbridge (James Livingstone & Frank Malcolm, trading as). Estates sequestrated April 22. Meeting to elect trustee and commissioners, Library Hall, County Buildings, Airdrie, on Monday, May 8, at 11.15 a.m.

Bankruptcy Proceedings.

CAMP, WILLIAM, trading as WILLIAM CAMP & COMPANY, Carr-lane, Slaithwaite, near Huddersfield, Yorkshire, electrical engineer. The first meeting of creditors was held recently at Huddersfield. The statement of affairs showed gross liabilities of £594, all of which was expected to rank, against assets of £100, or a deficiency of £494. Debtor attributed his failure to shortness of capital, bad trade, and ill-health. The case being a summary one, was left with the Official Receiver.

HENDERSON, Charles Archibald, 63, Queen Victoria-street, E.C. At the statutory first meeting of the creditors, held on Monday, the Official Receiver reported that, according to statements, the debtor, shortly after being demobilised in 1919, bought for £450, which he borrowed, the business of Allen &

McMaster, insulating materials merchants. The trading was a success until some nine months ago, when he found himself short of capital in consequence of guarantees. Certain of his customers also curtailed their credit when they heard that it was his intention to manufacture on his own account. He had been hoping from day to day that friends would provide the money necessary to equip a factory, but he had done practically no business for some months past. He roughly estimated his liabilities at £2 000, of which, he said, £500 was due to moneylenders and the balance in respect of trade accounts. Those liabilities were, however, apart from contingent liabilities amounting to £20 000 (less £2 000 repaid), which represented loans to him on security of life policies for £30 000. Those liabilities were guaranteed jointly and severally by certain other persons. He added that he had received no part of the loans in question nor any consideration, and that the money had been lent to another company. He had roughly valued his assets at £19 540, excluding the equity of redemption in a freehold house at Sutton. He attributed his present position to the failure to equip a factory to manufacture the goods in which he had dealt, and to heavy interest and loans and guarantees from friends. He was prepared to make an offer for the payment of 7s. 6d. in the £ to trade creditors. It was understood that for the purposes of such a proposal the family creditors would withdraw their claims. On behalf of creditors, Mr. Webb pointed out that the bankruptcy petition was adjourned for months to enable the debtor to make a proposal. He was not very hopeful. The chief creditor, however, remarked that he was in favour of an adjournment, and the Official Receiver thereupon adjourned the meeting until May 22.

MAIDMENT, Percy Charles, electrical engineer, &c., 13, Beauchamp-place, South Kensington, W. This debtor attended last week for his public examination on a statement of affairs showing liabilities of £1 688, all of which were expected to rank for dividend, and assets £92. Debtor stated that after he was demobilised in February, 1919, he entered into partnership with two other persons, and they began business as electrical engineers, under the style of Wright Brothers & Maidment, at 164, Sloane-street, S.W. They continued together until August, 1919, when the partnership was dissolved. The debtor said that he agreed to pay his late partners £4 250 for their interest in the business, stock, lease and fixtures, and he continued the business under the style of P. C. Maidment until March of last year, when he disposed of it for £4 500. He then began to trade as a builder, decorator and electrical engineer at 13, Beauchamp-place, where he carried on business until January, when his stock-in-trade was sold under an execution. He attributed his insolvency to lack of capital and to bad trade. His brother prepared a balance sheet in October, 1920, which disclosed an excess of liabilities over assets amounting to £800. In March, 1921, his brother left him, and the debtor, having no knowledge of book-keeping, had not since kept up the books. He realised that he was in a very bad way in October, 1920, but, notwithstanding the loss shown in the balance sheet prepared, he continued the business in the hope that trade would revive. He tried to find a purchaser for the business, and that he eventually did in March, 1921, when his liabilities approximately exceeded his assets by £1 500. Since starting the business in Beauchamp-place he had contracted further debts amounting to £100. To enable him to carry out the purchase he borrowed £3 600 from his bankers, which loan he had since repaid, and he also obtained a loan from his father, which was still outstanding. This was the only occasion on which he had been bankrupt. The examination was concluded.

VIVIAN, ALBERT, electrical engineer, 140, Gray's inn-road, W.C. Under a receiving order made against this debtor, on April 10, on the petition of the Burke Electrical Company, of Westminster, the act of bankruptcy alleged being notice given by the debtor on March 10 of suspension of payment, the statutory first meeting of creditors was held last week. The debtor in June, 1920, entered into partnership with another person, and they traded together as bakers' engineers in Birmingham under the style of A. Vivian & Company. The business was, however, unsuccessful from the beginning, and in March 1921, the partnership was dissolved; his partner taking over the assets and liabilities. He then met another person, who suggested that he should begin business by himself. Financial backing was promised provided that the debtor took two of this person's relatives into the business as employees. A sum of £355 was actually provided. The business, however, from the outset was not very brisk, and the coal strike affected his trade very adversely. Moreover, not having sufficient capital, the debtor was unable to buy advantageously, and his business rapidly declined. In January the other person, who had guaranteed his overdraft at the bank, stopped his account, at that time overdrawn to the extent of £140, and through his solicitors applied for repayment of his advances. The debtor, therefore, placed his affairs in the hands of another, who immediately took possession of the business and acted as trustee. A private meeting of the creditors was afterwards held, when joint trustees of the estate were appointed. In March he executed a deed of assignment of his property in favour of his creditors. He estimates his liabilities at £2,200 and values his assets at £140. He attributes his insolvency to depression in trade and to his having begun the business without sufficient capital. The case remains in the hands of the Official Receiver as trustee.

Arrangements for the Week.

FRIDAY, May 5th (to-day).

THE IRON AND STEEL INSTITUTE.

10 a.m. At the Institution of Civil Engineers, Great George-street, London, S.W. 1. Annual meeting.

ROYAL SOCIETY OF ARTS.

4.30 p.m. At John-street, London, W.C. 2. Lecture on "Imperial Wireless Communication," by Prof. W. H. Eccles, D.Sc., F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.
(LONDON STUDENTS' SECTION.)

7 p.m. At the Institution, Savoy-place, London, W.C. 2. Lecture on "Electrically Oscillatory Discharges," by Mr. R. P. Howgrave-Graham.

THE JUNIOR INSTITUTION OF ENGINEERS.

8 p.m. At Caxton Hall, London, S.W. Lecturette on "Gold Casting under Steam Pressure," by Mr. E. N. Ching.

EDINBURGH ELECTRICAL SOCIETY.

8 p.m. At Philosophical Institute, 4, Queen-street, Edinburgh. Annual meeting.

SATURDAY, May 6th.

ROYAL INSTITUTION OF GREAT BRITAIN.

3 p.m. At 21, Albemarle-street, London, W. 1. Lecture on "Industrial Relationships: (II.) The Problem of Structure," by Mr. D. H. MacGregor, M.A.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

6 p.m. At Cannon-street Hotel, London. Sixty-ninth Anniversary Festival.

MONDAY, May 8th.

ROYAL INSTITUTION OF GREAT BRITAIN.

5 p.m. At Albemarle-street, London, W. 1. General Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS.
(LIVERPOOL SUB-CENTRE.)

7.15 p.m. At Compton Hotel, Church-street, Liverpool. Third Annual General Meeting.

TUESDAY, May 9th.

INSTITUTION OF ELECTRICAL ENGINEERS.
(EAST MIDLAND SUB-CENTRE.)

6.45 p.m. At Loughborough College, Loughborough. Annual General Meeting.

THURSDAY, May 11th.

THE OPTICAL SOCIETY.

7.30 p.m. At the Imperial College of Science and Technology, London, S.W. 7. Discussion on "Motor-car Head-lights."

FRIDAY, May 12th.

PHYSICAL SOCIETY OF LONDON.

5 p.m. At the Imperial College of Science, South Kensington.

1. "A New Apparatus for the Measurement of the Polarisation Capacity of Platinum Plates in Sulphuric Acid," by Dr. A. Griffiths and Mr. W. T. Heys.
2. Demonstration of Some Electrical Properties of Neon-filled Lamps, by Mr. S. O. Pearson and Mr. H. St. G. Anson.

New Companies.

Gardner Engines, Ireland.

GARDNER ENGINES, IRELAND, LTD. (N.I. 23). Private company. Reg. in Belfast April 27. Capital, £3 000 in £1 shares. To carry into effect an agreement between Norris, Henty & Gardners, Ltd., and L. Gardners & Sons, Ltd., and to carry on business as mechanical, Electrical engineers, &c. Subscribers: C. Kendrick Edwards, M. R. Wylie. Secretary: Mary R. Wylie. Registered office: 65, 66, 67, Scottish Temperance-buildings, Donegal-square South, Belfast.

Invincible Electrical Engineering.

INVINCIBLE ELECTRICAL ENGINEERING COMPANY, LTD. (181 286). Private company. Reg. April 24. Capital, £1 000 in £1 shares. To carry on business as indicated by the title. First directors. J. H. Challinor, B. A. Kelsall, and C. J. Arnold. Registered office: 134, Park-lane East, Tipton, Staffs.

Sturge & Baker.

STURGE & BAKER, LTD. (181 382). Private company. Reg. April 27. Capital, £8 000 in £1 shares (1 500 6 per cent. cumulative preference and 6 500 ordinary). To take over the business of electrical accessories manufacturers carried on by W. H. Sturge and E. T. Baker at Premier Works, Sheepcote-street, Birmingham, as "Sturge & Baker." Permanent directors: W. H. Sturge and E. T. Baker. Secretary: E. T. Baker. Registered office: Premier Works, Sheepcote-street, Birmingham.

Winsor Engineering.

WINSOR ENGINEERING COMPANY, LTD. (12 171) Private company. Registered in Edinburgh April 25. Capital, £15 000 in £1 shares. Ventilating, heating, cooling, air conditioning, insulating engineers, &c. First directors: J. Marshall, G. Browning, and T. Neilson. Registered office: 41, Cogan-street, Pollokshaws, Glasgow.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by Messrs. Mewburn, Ellis & Co., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

Complete Specifications.

170 114 British Thomson-Houston Co. Ltd. & Whitaker, F. P. Dynamo-electric machines. (14/7/20.)
170 117 Nichols, E. F. Electric circuit closers. (16/7/20.)
170 148 Bolton, R. A. R. Construction of electric switches. (3/8/20.)
170 154 Franklin, C. S. Continuous wave telephony and telegraphy. (5/8/20.)
170 158 Bailey, H. & Pritchard, A. C. Means for use in the testing of internal combustion engine ignition apparatus as employed on motor vehicles and for remagnetising the permanent magnets of such apparatus. (14/8/20.)
170 170 Robinson, J. & Crowther, H. L. Apparatus for indicating the reception of sound, light, heat or electricity. (23/8/20.)
170 180 British Thomson-Houston Co. Ltd. (General Electric Co.). Electric regulating systems. (4/9/20.)
170 191 Staunig, K., Fritz, O. & March, A. Method of spectrum analysis of Röntgen rays and for apparatus therefor. (1/10/20.)
170 207 Dick, E. Electrical quick-acting step regulator. (4/11/20.)
170 237 Igranic Electric Co. Ltd. (Cutler-Hammer Manufacturing Co.). Electric switches. (16/2/21.)
170 327 Taggart, J. Scott-, & Radio Communications Co., Ltd. Construction of vacuum tubes and the like as used for radio-signalling. (10/6/20.)
170 331 Brecknell, Munro & Rogers, Ltd., & Willis, A. M. Bow current-collectors in overhead wire systems of electric traction. (17/6/20.)
170 344 Hanman, J. Sparking-plugs. (12/7/20.)
170 357 Poole, G. Portable dynamo-electric lamp. (14/7/20.)
170 371 Master, S. D. Trolley wheel guides for electric tration. (16/7/20.)
170 375 Stone & Co., Ltd., & Honey, A. E. Dynamo-electric machines. (16/7/20.)
170 377 Taggart, J. Scott-, Radio Communication Co., Ltd., & Turner, L. B. Trigger relays especially for use in radio communication. (17/7/20.) (Addition to 130 408.)
170 378 Taggart, J. Scott-, & Radio Communication Co., Ltd. Modulation systems and the like in radio comn.unication and the like. (17/7/20.) (Cognate application 25 066/20.)
170 385 Automatic Telephone Manufacturing Co., Ltd. (Automatic Electric Co.). Relays and their application to automatic telephone or like systems. (19/7/20.)
170 400 Riley, G. B. Telephones. (20/7/20.) (Cognate application 4 737/21.)
170 401 Nadaud, C. L. J. B., & Young, F. Electric switches. (20/7/20.)
170 402 Reyrolle & Co., Ltd., A., & Harriman, W. A. Contacts for electric fuses, cut-outs, and the like. (20/7/20.)
170 414 Lamb, H. R., & Huartson, H. Method of and apparatus for conveying electric current to a movable truck or the like. (24/7/20.)
170 420 Sykes Interlocking Signal Co., Ltd., W. R., & Sykes, F. J. Mercury signal arm contact. (26/7/20.)
170 435 C. L. I. Manufacturing Co., Ltd., & Watson, E. A. Control devices for electric circuits. (9/8/20.) (Cognate application 27 360/20.)
170 459 Joseph, B. C., & Joseph, N. C. Electrically-heated cooking utensils. ((27/8/20.) (Addition to 158 073.)
170 469 Brown, A. G. Sparking-plugs. (6/9/20.) (Addition to 145 348.)
170 472 Atkins, J. Electric switching systems for charging batteries. (8/9/20.)
170 605 Jackson, W. J. Mellersh- (Taylor, A.). Radio-telegraphy signalling systems. (12/4/20.)

APPLICATIONS FOR PATENTS

April 18, 1922.

10 728 D. C. Williamson. Circuit controlling devices for ignition systems.
10 744 H. J. Osborn. Incandescent lamps, wireless valves, &c.
10 754 S. R. Gibbon. Electric switches.

CONTENTS.

Notes of the Week.

What More Wireless Means.

As we pointed out a fortnight ago, the awakening of public interest in the employment of wireless methods for the dissemination of news cannot fail to have a satisfactory influence on the progress of that branch of the electrical industry which is concerned with such matters. This progress will be accelerated by the decision of the Postmaster-General to establish a number of broadcasting stations which will be operated by approved British firms, the selection of which we hope will be as wide as possible. But at the same time it will bring with it an increase in responsibility. For the wireless amateur will require simple, cheap, and efficient apparatus if he is to be able to take advantage of the facilities provided, and equipment of the same qualities will be equally required by the "broadcasting" stations. Designers and manufacturers will, therefore, have to devote close attention to a study of all the questions which the production of this class of wireless apparatus will involve, and to keep themselves acquainted with what is being done in both theoretical and practical fields. To ensure that acquaintance is obviously the duty of a technical journal.

"The Electrician" and Wireless.

For that reason we propose to devote a certain amount of space in The Electrician, which appears on the second Friday of each month, to a consideration of technical wireless matters, in the hope that by so doing we may assist in the "broadcasting" of information on this most important question. Not the least useful part of this scheme will be the series of articles by Prof. G. W. O. Howe, which we shall publish in these issues, in which he will discuss theoretical and technical matters of a controversial character connected with the progress of wireless telegraphy and telephony. In this particular issue Prof. Howe deals with the recording and printing of high-speed radio signals, and points out to how large an extent the economic success of long-distance radio-telegraphy must depend on the development of both transmitting and receiving apparatus for this purpose. He mentions what has been actually done in this direction, and describes a new type of siphon recorder which has been developed by the Radio Corporation in America. This is a matter to which it will be agreed close attention must be paid, and the development of which will be of the greatest of use for the purposes we have mentioned above.

A Survey of Wireless Literature.

There is, perhaps, no electrical subject upon which more is being written at the present time than that which can be conveniently placed under the heading of radio communication. But the earnest seeker after truth finds the distribution of the information so wide that it is a matter of considerable difficulty not only to find any particular detail for which he is seeking, but to discover what has been written on a particular subject. We propose to make this task easier by publishing in our second issue each month references (they are hardly abstracts) to articles and other publications on wireless subjects, always excepting patents, which will be found, as heretofore, in our Patent Record. This last is an important reservation, for in modern patent literature there are perhaps to be found the most accurate indications of the trend of wireless progress, and, not less interesting, the attempts and failures that have been made to reach success by a particular route. It may also be pointed out that a great deal of useful wireless information is to be found in publications which are not strictly technical, and to which the scientific worker does not have access or of which he is not even aware. That gap will, we hope, be filled by the feature which appears for the first time in our columns this week.

Imperial Wireless Communication.

In the Paper on "Imperial Wireless Communication," which he read before the Dominions and Colonies and Indian Sections of the Royal Society of Arts last Friday, Prof. W. H. Eccles took the wise course of summarising in non-technical language what has been done to bring radio communication to that state when it can not only render useful international service, but can be used with pleasure and profit by any ordinary human being. His avowed object was to publish information which ought to be in the possession of those who wish to form their own opinion on the proposal to erect an Imperial Wireless Chain. And though some of his conclusions were traversed by Mr. Godfrey Isaacs in the course of the discussion, they are not the less valuable for that. Prof. Eccles, of course, represents the official view; Mr. Isaacs an alternative method of providing a similar service. It is hardly likely they would agree on all points.

The "2 000" Mile Scheme.

One of the points of difference seems to be the advisability or otherwise of working on the "2 000 mile scheme" recommended by the Imperial Wireless Committee. Mr. Isaacs, argued against the scheme, but Prof. Eccles, by means of an interesting meteorological analogy, was able to show the technical disadvantages of building stations with ranges beyond that limit. Purely from the traffic point of view, the argument in favour of the shorter range is also the more cogent, as messages can be both transmitted and received at the intermediate stations, and a more distributed and efficient communication thereby maintained. It is significant that Prof. Eccles's review states that few stations are working normally at a much greater range than 2 000 miles, though, of course, the extreme range at times may be much greater for reasons that are well-known.

The Patent Situation.

Speaking upon the patent situation, Prof. Eccles also made some interesting remarks. Except for the Meissner "feed-back" invention, owned by the Marconi Company, the heterodyne patents of the Metropolitan-Vickers Company, and two small German patents, no other patents of outstanding fundamental importance appear to be employed, and wireless communication is, therefore, free to develop on the technical side without what cannot be regarded other than as a most serious stranglehold. We hope that the other kind of monopoly which might be brought about by business and financial combinations may also be dissolved, if necessary by Government action. It is essential for the general good that it should.

Amateur Wireless in the United States.

The possible wide extension of the use of wireless equipment by amateurs as a result of the concessions which it is understood are to be granted by the Postmaster-General receives striking confirmation in reports that have been published in the United States, where the use of radio apparatus has evidently become a craze. It is stated that there are now about one million people in that country who amuse themselves by listening to the broadcasting of news, picking up "commercial codes," and taking the time from Arlington. As there were only forty thousand receiving stations a year ago, the rapid increase is truly astonishing, even for America. On the industrial side, we note that organised efforts are being made to sell radio receiving apparatus and equipment, and to develop the business as a distinct branch of the electrical industry. There is, however, another aspect of the matter, as we pointed out last week, for the multiplication of stations has made the exercise of some control by the Government necessary, and this will not appeal to the average American, who strongly resents any check on his actions.

Control of Radio Apparatus.

The Technical Committee of the Radio Control Conference have, in fact, issued a long report, which recommends complete control by the Department of Commerce over transmitting stations, though receiving stations are to be exempt. It is also recommended that wave lengths below 6 000 metres should be reserved for radio-telephone service, but wave lengths which have become standardised for telegraph service within this range, such as SOS signals, are to be retained. The present development of radio art warrants the employment of twenty different wave bands, of which seventeen are below 2 000 metres, and the Committee consider that in assigning these wave lengths the "broadcasting" service should have priority; but in dealing with this "broadcasting" the Government should come first, then education and public work, with private broadcasting (including entertainment, news, &c.) third, and toll broadcasting last. Amateurs are to have wave lengths of 150 to 275 metres reserved for them, but are to be given some opportunity to use experimental wave lengths. It is further proposed to limit the amount of power used in transmitting stations, in order to confine each of them to some special zone, and thus minimise interference with one another. This is an excellent provision, and a Bill has been introduced authorising the Department of Commerce to prevent the establishment of a transmission monopoly and to regulate the hours during which sending stations may operate. We do not envy the task of the Government officials who will have to enforce these regulations. They will have a lively time, and what is more—an unusual thing with officials—they will fully earn their salaries. What we may learn from what has happened is that rules for amateur wireless should be laid down at once, not in a rigid, restrictive spirit, but so as to protect the community generally.

Ultra Vires.

We wonder how many electricity supply underakings commonly perform actions which are *ultra vires*, or, on the other hand, fail in some respect to comply with some stipulation that is laid down by statute. The fact is that many supply engineers are but imperfectly acquainted with the contents of the various Acts that are supposed to govern their actions, and it would be interesting to know how many officers of position in undertakings could acquit themselves satisfactorily under even an elementary catechism of these formidable documents. It is true to say that every one in any position of authority ought to have at his fingerends the chief points in electricity supply legislation, and this should not be difficult, as the public Acts make in the aggregate only a quite slender volume. Nevertheless, we are often astonished at the vagueness shown by many officials on points connected with their own special work. Most of them, of course, know generally what is required, but that is quite a different thing from being able to give the exact text. Fortunately, consumers are more ignorant still, though this is no argument for a state of affairs which cannot be commended.

An Illegal Advertisement.

As an example of what we mean we may cite a case which occurred in the Midlands. A large supply undertaking

advertised that a special discount would be given for a certain period to all new consumers. This policy was, of course, adopted merely as an advertisement, and as such is to be commended as the awakening of the commercial spirit. Unfortunately, it ignores the stipulation in the Electric Lighting Act that preference must not be given to one consumer as against another of the same kind. So far as we know, no question was raised, probably because no one knew of the statutory provisions governing the matter. But such ignorance or indifference cannot always be defended, and an intimate acquaintance with the few Acts governing the industry is certainly a duty incumbent on everyone to whom any section of an electricity undertaking is entrusted.

Paying for Electricity Inquiries.

Under Section 34 of the Electricity Supply Act, 1919, the Electricity Commissioners are empowered to make rules as to the cost of any inquiries they may undertake. The draft rules, which have now been issued, scheduling all costs and expenses of the Commissioners arising out of any inquiry held by them, are, therefore, of interest. They lay down that the costs shall be borne by the parties concerned, or by such of them and in such proportions as the Commissioners may direct. As heretofore, of course, the individual expenses of the various parties at all public inquiries will be borne by themselves, and the Order refers to the special expenses incurred by the Electricity Commission, the general expenses of the Commission being borne by the industry as a whole. This seems to be the most equitable procedure, and though we do not know on what basis the Commissioners will apportion the expenses, we hope the effect will be to get rid of the long-windedness which has been too prevalent. If the parties find that the more they talk the more they have to pay a most desirable succinctness will result. To act in this way would, therefore, be well-warranted self-protection on the part of the Commissioners, since they are already worked hard enough without having to spend valuable time in listening to long-drawn-out arguments and counter-arguments that everyone in the industry by this time knows by heart. Arguments, too, which fill legal pockets, drain the industry, and lead nowhere.

The Gas Light and Coke Company's Order.

It is not often necessary for us to deal with the Legislation governing the supply of gas, but the Special Order of the Gas Light and Coke Company contains some provisions of such far-reaching effect that attention must be called to them. The Company, which seeks authority to purchase the Ilford Gas Company's undertaking, also desires to obtain power to lay pipes through parts of premises for the supply of other parts in different occupation without apparently obtaining either the consent of the owner or occupier. Only twenty-four hours' notice of the intention to lay the pipes is to be given, and neither the owner nor occupier is to have a voice in determining the position of the pipes or the manner of laying! If a similar suggestion was made by some electricity supply undertaking what an outcry there would be by the gas journals.

Control of Fittings.

This, however, is not the only high-handed procedure which the Company would like to adopt, for it is also seeking power "to specify the size and material of the pipes, with the fittings thereof, which are to be laid by the owner or occupier of any premises, either in the first instance or on the occasion of any renewal." Notice of any such work must be given to the Company which is to be empowered to approve or disapprove of the work, and in case of disapproval to refuse a supply of gas. While we sympathise with the desire to secure proper fittings and good workmanship, the power sought is altogether too wide for the protection of the Company's interests, and goes farther than the corresponding powers of electricity supply authorities. The only safeguard which the prospective gas consumer will have is a right of appeal to a Petty Sessional Court. In practice this will prove quite ineffective, as magistrates have little or no technical skill, and a monopolist Company like the Gas Light and Coke Company will have pretty much its own way. A better plan would be to refer any dispute concerning fittings to an engineering inspector of the Board of Trade or to an arbitrator.

Minimum Charge to be Enforced.

There is a third point in the Company's Order which seems to call for some modification. The Company wants to be in a position to make a minimum charge, not to exceed 25s. a quarter, for a stand-by supply of gas. The principle of the stand-by charge is now well known and is generally inserted in Electricity Supply Special Orders and in Gas Acts and Orders, but a sum of £5 a year is an exorbitant charge and cannot be justified. It would appear to be required as a menace to would-be users of electric light and power, who may wish to retain a gas supply for occasional heating or some other purpose, rather than as a protection to the Company. Those who wish to secure modifications of the clauses we have referred to should take steps to make representations at once to the Board of Trade. We believe the electrical industry is not likely to be affected by the provisions, which, if adopted, will assist rather than retard the progress of electricity supply. Their real effect to us therefore will be beneficial, though that is not their evident purpose.

Supply of Domestic Electrical Apparatus.

With the rapid expansion of the applications of electricity, particularly in the domestic sphere, new demands and changes in practice have arisen. These developments, which are the outcome of public needs and requirements, are of gradual growth, and frequently their true significance and trend are not understood or appreciated at the outset by those who are most interested or affected. We are afraid that many electrical contractors and supply dealers are not yet sufficiently alive to the need for meeting the increasing demands for domestic electric apparatus. This business has already become an important branch of the industry, and in the course of time it will attain to far greater importance. Therefore, we hope that steps will be taken to keep the supply of vacuum cleaners, electric washing machines, and other domestic apparatus in the hands of those who are competent to handle it. From the letter of Mr. Morton, which appears in another column, there would seem to be some danger of this lucrative trade being captured by those engaged in another trade. Apparently others believe there is money to be made by catering for modern domestic requirements, and we venture to suggest that those whose primary duty it is to develop this growing branch of the electrical industry should organise themselves so as to keep this trade in their own hands.

Inadequate Illumination and Miners' Nystagmus.

Much is heard in these days of the importance of good industrial lighting, but we doubt if there is any problem more urgent than the provision of adequate light in mines,

where work is carried on in such abnormal and difficult circumstances. It may be recalled that this point was illustrated in a discussion before the Illuminating Engineering Society last year, when a concensus of opinion emerged that the disease of the eyes known as miners' nystagmus is due mainly to work by insufficient light. This conclusion is now endorsed in a report recently issued by a committee working under the Medical Research Council. The committee unanimously regard deficient illumination as the chief cause of this disease. The small candle-power available from many forms of miners' lamps, the distance at which they have to be placed from the working surface, the very dark nature of the coal-surface itself, and the effect of coal dust and grime in absorbing light are all contributory factors. The committee suggest that an increase in candle-power to at least 2 to 3 candles is desirable, that lights might with advantage be so designed as to be used on the miner's head and so brought nearer the work, and that in parts of the pit other than the coal-face whitewashing would form a useful method of increasing the available illumination. If such remedies are adopted it is believed that miners' nystagmus of sufficient severity to cause disablement can, by degrees, be entirely prevented. We should like to take this opportunity of referring to the very valuable pioneering work done in this field by Dr. T. Lister Llewellyn, the secretary of the committee, who was responsible for opening the discussion before the Illuminating Engineering Society last year. It is gratifying that this country has taken a leading part in this research, and we have no doubt that makers of miners' lamps will be quick to respond to the requirements indicated as essential.

International Radio-Communication.

A most important measure of agreement was arrived at last summer at the meeting of the Technical Committee on International Radio-communications, as appears from the report, printed in the French and English languages, which has just been issued. This Committee, which comprises representatives of the Governments of the United States, France, Great Britain, Italy, and Japan, has been considering a number of important questions, and while decision on some of these is left in abeyance, in other cases complete agreement has been attained.

Ether Becoming Too Small.

To those in touch with wireless matters, it has been obvious for some years that the ether—usually considered as of vast extent—was becoming much too small, in the two-dimensional sense, for the enormous number of electrical signals continually being shot into it, and that unless some systematisation, based upon international agreement, were inaugurated, this valuable method of communication would suffer a setback owing to the chaotic conditions which the near future would probably bring. For this reason little surprise will be felt that the deliberations of the Committee were concerned almost entirely with the broad, yet enormously important, question of the classification of waves and their distribution among the various communication services, so that unnecessary interference is avoided.

Fourteen Important Points.

For the benefit of those who have not yet seen the Report, it may be mentioned that after dealing with certain small matters such as nomenclature, and the use of frequencies (kilocycles per sec., kc/s) rather than wave-lengths, the remainder of the Report is concerned with fourteen questions, to which answers were to be supplied by the Committee.

The first question, which deals with the classification of waves, furnishes the key to the objects of the conference. The next three questions are concerned only with particular wave-lengths. Question 5 raises the matter of the privileges of different classes of waves, Questions 6 and 7 further dealing with this. Questions 8 and 9 consider undesirable emissions; Question 10, the long-wave services. Question 11 asks for a definition of normal range, while Nos. 12 and 13 deal with radio-beacons and radio-goniometry. Question 14 was left open in order that other matters which might be brought forward by the delegates could be dealt with under this head.

Classification of Waves.

The Committee has adopted a classification under which five *types* of waves are recognised, namely, four types of A or continuous waves, and a fifth type, B, damped waves. The four A types of waves comprise A for unmodulated continuous waves, A1 for key-modulated C.W., A2 for audio-frequency modulated C.W., and A3 for speech-modulated C.W. Within each type waves are classified according to the degree of interference they produce at some distance away, this degree being estimated by the "equivalent decrement" (more fully defined in the Report). In the waves of Class 1, the equivalent decrement may be anything from zero up to 0·005 in Class 2, from 0·005 to 0·02; in Class 3, from 0·02 to 0·08 while in Class 4 it may range from 0·08 to 0·10. Under this scheme it results that the only type of wave permissible for stations of longer wave-lengths than 8 000 m. is Type A1. Class 2. In the next lower range of wave-lengths, namely, 2 850 to 8 000 m., the damping of waves used for high-speed signalling on waves of Type A1 has to be such that the emission complies with the requirements for Class 2.

Wave-Lengths for Radio-Telephony.

Now that so much interest is taken in wireless telephony the question of the range of wave-lengths permitted is a matter of concern to numbers of people. For fixed stations this has been agreed on as from 1 550 to 1 650 m., and for mobile services from 300 to 340 m., but using continuous waves of Type A1 only.

Long-Wave Fixed Services.

The recommendation that a study of the world needs for wave-lengths above 2 800 m. should be made should be of value in preventing the indiscriminate putting into operation of mammoth stations without due regard to the interference which may be caused with stations already working; and the fact that it is proposed that each nation should supply to the next International Conference a table of data relative not merely to stations in operation, but to those which are to be put into operation during the subsequent period of five years, will assist this laudable endeavour. A further recommendation, that a nation, before employing a new wave-length, should endeavour to utilise the directional properties, is of interest as showing that more attention will have to be paid to improving the directional qualities of transmitters using long waves, in the sense of narrowing the beam of rays emitted, as in the recent attempt of Franklin with very short waves.

Normal Range.

The normal range is assumed to be the distance obtained from the formulæ in the report, calculated on the basis of an induced E.M.F. in the receiving antenna of 150 mV per metre. In a table are shown the values of hI (the

product of the radiation height of the antenna and the current at the base of the antenna) that are necessary at the transmitter for this value of 150 mV to be obtained in the receiving antenna at ranges of 100 to 300 km. for waves of 450, 600, and 800 m.

The ranges adopted for mobile, short range, and long range beacons are respectively 10, 30, and 200 nautical miles. Radio-goniometric coast stations must be able to give bearings either on 600 *or* 800 m. only, or else on 600 *and* 450 m. or 800 *and* 450 m.

Distribution of Wave-Length Amongst the Various Services.

Perhaps the most interesting thing in the whole report—interesting because it has never before been shown up clearly—is the graphic chart given at the end, showing the distribution of frequencies and wave-lengths among the different services. The range of wave-lengths dealt with is 200 m. up to 5 000 m., and the distribution is shown among the following four classes of service: Mobile, fixed, military, special—for each type of wave and class. Little fault, it is felt, can be found with the rather extensive bands of wave-lengths appropriated for the military services. The mobile services, however, also claim a fairly extensive series of bands, and the result is, that only comparatively thin bands are left for the fixed services—namely, four, at 200 to 280 m., 950 to 1 050 m., 1 550 to 1 850 m., 2 850 to 3 300 m., and 3 900 to 4 800 m. respectively. These bands are, further, only of this extent for the highest class of wave, A1, there being only three bands of reduced width for the more damped Class A3 wave. For the special services there are six wave-lengths allotted, not bands; these are well known (450, 600, 800, 1 000, 2 100, 2 650 m.).

Post Office Matters.

It is often our duty to deal in these columns with the ethics of municipal trading as evidenced by the electricity supply departments all over the country. Our view is that consonant with financial stability, the prices charged should be kept as low as possible, and that under no circumstances should the electricity consumers' pockets be searched for the benefits of the general body of ratepayers. These views are, it will be agreed, sound enough, and are equally applicable to Governmental as to municipal trading. In other words, to fix the postal rates high in order to relieve the general body of ratepayers is economically unsound, and is, moreover, which is an added argument against it, likely to defeat its own object. The operations of the Post Office, which is the principal Government trading department, should, therefore, be governed by the principle of keeping the rates at the lowest possible level. For it is one of the disadvantages of any public trading department that it is not necessary for it to make a profit, but at the same time it is important that it should not be allowed to do so.

Trade and Lower Postal Charges.

The Postmaster-General is, therefore, to be congratulated upon reducing the postal charges, and may also be adjured to pluck up his courage, as he seems a little fearful of the result. For this reduction will assist trade, increase revenue, and will, we hope before long, make still further reductions possible. The figures on which these reductions are based are of interest. In 1920-21 there was a loss of £7 300 000. In the first six months of last year there was a loss of £2 800 000, and in the second six months, when the increased charges began to operate, a surplus of £1 000 000, leaving a deficit of £1 800 000, which would have been the enormous sum of £5 000 000 but for the increased charges. Owing, however, to the present improved position, which is entirely due to a reduction in expenditure from £67 120 000 to £53 800 000, the estimated surplus in 1922-23 with the old charges would have been £9 300 000. The Postmaster-General is, therefore, quite right in reducing the charges as he has done, and quite right, too, to resist the attempt of the Treasury to sequester the balance.

It may be pointed out that the reduction now given will not entirely wipe out the surplus, but Mr. Kellaway feels it is wiser, in view of the uncertainty as to revenue, to go slowly. We think that he is a little pessimistic, as with lower charges, especially on printed matter, the revenue might be considerably increased without any difficulty. The Postmaster-General must also turn his attention to the reduction in the rates for telegrams and parcels.

Telephone Enterprise.

To electrical engineers, however, the most interesting portion of the Postmaster-General's review, apart from that on wireless broadcasting, upon which we comment elsewhere, is that which deals with the telephone system. We are glad to see that the report of the Select Committee on this ever-burning subject has induced Mr. Kellaway not only to reduce the present high charges, but to prepare a scheme of development on enterprising lines. It is a good beginning, which will have good results, especially if the pressure is kept up. By this time the Post Office Engineering Department should have caught up with its war arrears, and should be in a position to launch out into a development which is badly needed.

This development will be encouraged by a reduction of the rental to private users by 30s. a year, by a reduction in the local message rate from 1½d. to 1¼d. per call, by a 25 per cent. reduction on trunk calls between 2 p.m. and 7 p.m., by improved facilities in country districts, by the abolition of local fees on the longer trunk calls, and by a reduction of the hotly-resented mileage charges from £10 to £8 per mile. This, once again, is a good beginning, but progress must go on at the same rate.

High Charges No Check on Progress.

It is interesting to note that in spite of the present high charges the total number of telephone stations on March 31 was 995 242, an increase of 16 991, and that the total number of new subscribers was 75 000, and the number of cessations 64 000, of which 29 000 were due to an increase of tariff. The remainder are probably explained by trade depression, and, we hope, by the gradual cessation of Government departments' activities. During the year 530 rural call offices were opened, while 3 290 party line subscribers were taken on, showing that the prejudice against this system of inter-communication is departing. This is satisfactory as far as it goes, but it does not go far enough. For, as Sir Henry Norman said, in the course of the debate: "The Post Office must do what any business man would do—reduce charges, risk a gamble, and advertise. The Postmaster-General must thrust the telephone down the throats of the people."

Economy a Necessity.

But what is wanted more than anything else in the Post Office, as in other branches of the Government service, is rigid economy. The lack of necessity of obtaining a profit, which we mentioned above, is inclined almost unconsciously to induce invertebrateness and to engender a disregard of these true principles of trading, by following which alone can true success be obtained.

The Recording and Printing of High-Speed Radio Signals.

By Prof. G. W. O. HOWE.

There can be little doubt that the future economic success of long-distance radio-telegraphy depends to a large extent upon the development of reliable high-speed transmitting and receiving apparatus. The speed of hand-sending and direct telephonic reception cannot exceed about twenty-five words per minute, and the large amount of capital represented by the equipment of a high-power radio station cannot obtain a satisfactory return on the limited amount of traffic which it is possible to put through at this rate. The Wheatstone automatic working over ordinary land lines is capable of transmitting and receiving at speeds of 300 to 400 words per minute, and the radio engineer cannot regard the wireless problem as satisfactorily solved so long as the speed attainable is very much inferior to this figure.

Is the Limitation in the Transmission or Reception?

Whether the limit is at present imposed by the transmitting or by the receiving apparatus it is difficult to say. In a paper recently read before the Institute of Radio Engineers, Mr. Weinberger, of the Radio Corporation of America, stated definitely that "the limitation of working speed is practically confined to the receiving side of the radio system, so that it is obvious that increased speed possibilities must be obtained entirely by the development of receiving apparatus." In our opinion, this is an unduly optimistic view of the position with regard to high-speed transmission, although the thermionic valve has done much to reduce the instrumental difficulties on the transmitting side.

In discussing the Hoxie recorder in the same paper, the author states that "it has extraordinarily high speed capabilites (far in excess of what is actually required)," which certainly suggests that the speed is limited elsewhere than in the recorder. Hoxie himself, in describing his recorder on another occasion, showed a record taken at 600 words per minute.

The Lorenz and Hoxie Recorders.

One of the first to develop a system capable of recording radio signals at high speed was C. Lorenz, who in 1908-9 adapted the Einthoven string galvanometer with photographic recording and automatic development and fixation. It was operated by a crystal detector, and in the absence of reliable amplifiers it is not surprising that it was little used on a commercial scale, although very good experimental results were obtained on high-speed signals from Poulsen arc transmitters. It was capable of operation at 300 words per minute. The Hoxie recorder, which has been developed by the General Electric Company of America within the last three or four years, also employs photographic recording, with automatic developing, fixing, washing, and drying.

The actual recording instrument is really a vibration galvanometer inserted in the anode circuit of the last valve of the audio-frequency amplifier and tuned to the note frequency, which, in the case of continuous wave transmission, is adjusted by means of the local heterodyne generator. The coils and polarising magnets of the galvanometer are fixed, and the received signals cause the vibration of a thin iron strip stretched between the poles of the magnet; this movement of the strip is transmitted by a light rod to a mirror rotating about a knife-edge on jewelled bearings.

This recorder has been used at several stations in the United States on Transatlantic work, and, as already mentioned, can operate at speeds up to 600 words per minute. A single 1 000 foot roll of sensitised paper records about 10 000 words, and this suffices for several hours at the speeds of forty to fifty words per minute commonly employed in high-speed transmission. One of the great advantages of the Hoxie recorder is the large degree of freedom from interference obtained by the sharp mechanical tuning of the vibration galvanometer to the audio signal frequency. This is enhanced by shunting across the instrument a sharply tuned, closed oscillatory circuit, which acts as a shunt for all but its resonant frequency.

Phonographic Recording.

Quite a different direction along which much work has been done is that of recording the high-speed telephonic signals upon the wax cylinder of a phonograph or upon the steel wire of a telegraphone. The instrument is then run at a reduced rate, and the message read by means of a telephone receiver, as in the dictaphone. A limitation is imposed on this method by the fact that the pitch of the note is reduced in the same ratio as the speed. One advantage of this method is that it utilises the operator's power of discrimination between the signals and disturbances due to other stations or atmospherics; it has the disadvantages of being expensive in operation, of allowing a considerable time to elapse before any faults of transmission or reception are discovered and reported to the transmitting station, and of leaving no permanent record of the message as received.

In the very early days of radio-telegraphy it was considered essential to record the signals, and telephonic reception was unknown. Two methods were employed; the Marconi coherer operated a Morse inker, and gave dots and dashes on the tape, whilst the Lodge-Muirhead mercury and steel wheel detector operated a siphon recorder, and gave a line with humps of shorter or longer duration. Both these methods have lately been modified and applied to the recording of high-speed signals, using, of course, modern methods of detection, amplification, and rectification, by means of thermionic valves.

The British and German Post Office engineers have developed methods in which the beats produced by the local heterodyne are rectified and, through an intermediate relay, caused to operate a Wheatstone receiver, in which the message is recorded as dots and dashes on the tape.

A New Type of Moving-Coil Siphon Recorder.

The Radio Corporation of America have lately developed a new type of siphon recorder, which was very fully described in the paper by Weinberger referred to above. One advantage of the siphon record, as compared with that of the Wheatstone, is that it is easier to detect and allow

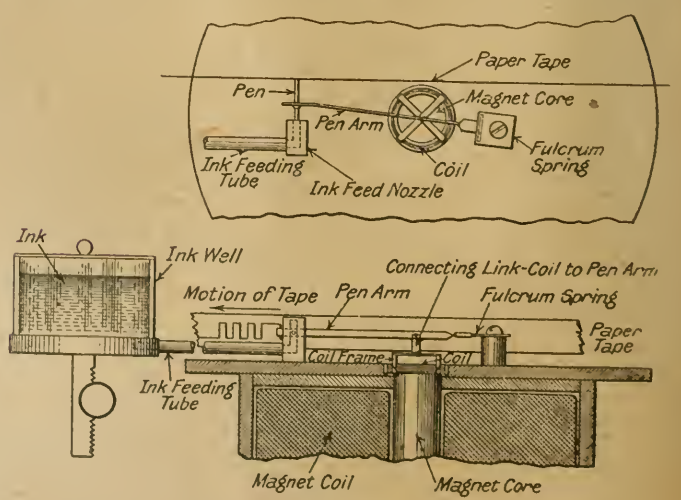

Fig. 1.—Essential Elements of Ink Recorder.

for the effects of atmospheric disturbances in the continuous ink line of the former than in the dots and dashes of the latter.

The new siphon recorder, or ink recorder, as its designers prefer to call it, is a very robust and well-designed apparatus. The circular moving coil is very light, and moves

vertically in the annular gap between the top of the central vertical core and the surrounding iron cover of a cylindrical electromagnet. The moving coil hangs, by means of an aluminium link, from the spring-supported pen-arm, which

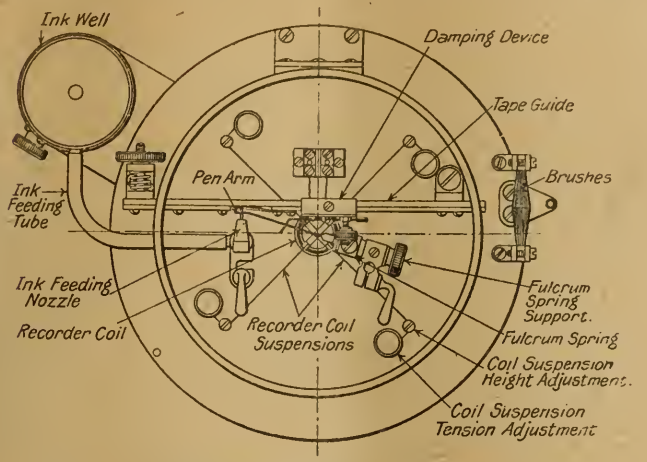

Fig. 2.—Ink Recorder, Commercial Model, Top View.

carries a pen consisting of a short piece of fine brass tubing. One end of this pen-tube moves over the surface of the paper tape whilst the other moves freely up and down in a groove in a fixed metal block, the groove being kept charged with ink by means of a flexible tube connecting the block with an ink-well, the height of which can be adjusted to maintain the ink level at the correct height. The slot being only a sixteenth of an inch wide, the surface tension prevents any spilling of the ink. Details are given in the accompanying illustrations.

The moving coil has 600 turns, a resistance of 1 000 ohms, and gives a full-sized record of $\frac{1}{8}$ in. at 100 words per minute, with a current of 4 mA. For higher speeds the fulcrum-spring which carries the pen-arm has to be changed, and at double the above speed double the current

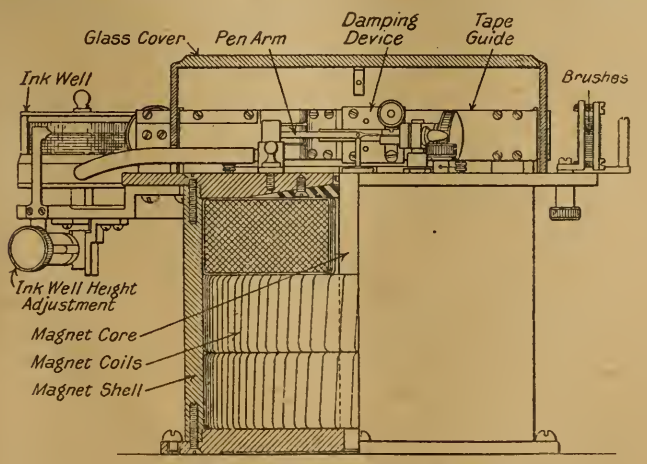

Fig. 3.—Ink Recorder, Commercial Model, Section.

is required. On its way to the recorder the paper-tape passes through a pair of brushes, which remove any paper dust which might clog the pen. The friction of the pen on the paper does not provide sufficient damping, and a special damping device is fitted to prevent over-shoot; this device is of the simplest character. The pen-arm moves between the prongs of a lever, which it is forced to carry with it towards the end of its travel, either up or down; this lever is held friction-tight between two washers, which are forced together by a spring, which can be adjusted by means of a milled nut.

A motor-driven tape-puller is installed at some distance from the recorder, the tape passing in front of the clerk or clerks on its way from one to the other. These clerks read the message from the tape and record it directly on typewriters. A single operator can take down the message up to a speed of forty-five words per minute, but above this several operators, each with his typewriter, have to be spaced at distances of 10 ft. along the tape, the first man doing what he can as the tape passes him, and marking on the tape where he commenced and finished; the second man starting in where the first finished, and so on.

This sounds very cumbersome, and suggests a weak link in the high-speed chain.

Although the Radio Corporation transmitting aerial at Long Island is 18 miles away from the receiving aerial at Riverhead, they are both connected by land lines, and suitable relay and transfer apparatus, to the operating office in New York City, where the transmitting clerk sits at the

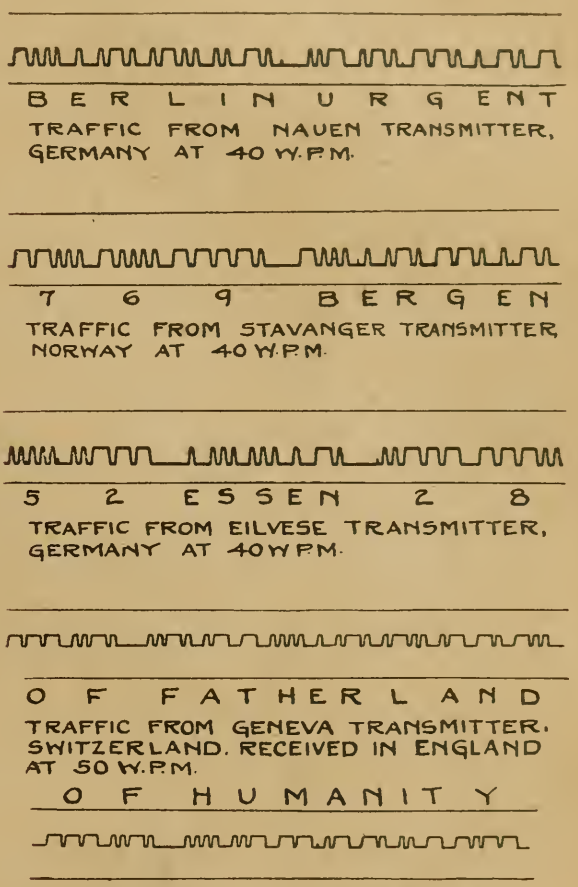

Fig. 4.—Typical Ink Recorder Tapes.

same table as the receiving clerk, so that the latter can immediately report any faulty reception to the European transmitting station and request any necessary repetition.

The Use of the Creed Printer.

The only alternative available at present to the transcription of the tape is the installation of that triumph of ingenuity, the Creed Printer. In this system, which is being used to some extent both in this and in other countries, the received signal, after passing through the usual amplifiers, detectors, and rectifiers, operates through relays the slide valve of a pneumatic perforator, thus giving a perforated Morse record, which is then fed into the Printer proper, which is essentially a pneumatically operated typewriter controlled by the perforations of the tape passing through it. This delivers the message printed directly in Roman characters. Although in use on some Anglo-Continental services, we do not know whether it has yet been successfully employed on long-distance work, where the factor of safety against atmospheric and other types of interference is necessarily greatly reduced.

The death occurred at Tynycymmer Hall, Porth, on Monday of Mr. W. H. Mathias, a director of the Treforest Electrical Consumers Company and a leading public figure in the Rhondda Valley for some forty years. Mr. Mathias was seventy-seven years of age.

High Voltage Switchgear Design.

By W. A. COATES.

(*concluded from page* 530.)

The problem of building electrical equipment for the high voltages which are now becoming common is mainly one of insulation. Two main types of insulation are required, that which merely supports the conductor and that which insulates the conductor where it passes through an earthed body. In high voltage work the limitations in design are mechanical rather than electrical, and in other ways greater simplicity is possible than at lower pressures. Though high-voltage gear was at first contained in cubicles, it was soon found that this was unnecessary, while in 1908 *the advantages of placing the gear out of doors was discovered. Mr. Coates discusses at length the details of modern outdoor switchgear compared with indoor equipment, and points out its economic and engineering advantages.*

Details of 100 kV Scheme.

In Fig. 6 is reproduced the section through the power-house of the Tata Hydro-Electric Company, Ltd., Bombay. This layout may be taken as a sound engineering design, without any unnecessary elaboration or waste space. The ground area occupied is, in fact, unusually small, due to the double-floor arrangement. The step-up transformers, which are in single-phase units, are placed in line, each within its own cubicle, which is provided with a roller-type fire-door. Along the front of the transformer cubicles is laid a pair of rails, carrying the transfer truck employed when it is necessary to remove any transformer unit for repairs.

The high-voltage oil-switches are arranged in a single row on the upper-floor. The transformers, rather than the switches, control the length of building required, so that an extremely simple supporting structure is possible for the busbar and outgoing isolating switches.

The electrolytic lightning arresters for the outgoing lines also are on two floors. A somewhat unusual arrangement is adopted in that the short-circuiting device for the horns is operated from the ground-floor. Since it is desirable for the operator to see the arc when charging his lightning arresters, the more usual practice is for the short-circuiting lever to be on the framework carrying the horn itself.

The isolating switch in series with the electrolytic arrester, is not generally provided, since the horn itself can be swung wide open, and thus acts as an isolating device.

Alternative Outdoor Arrangements.

For the purposes of illustration alternative arrangements of the high-voltage equipment have been prepared, everything being out of doors. With these schemes, in addition to the generator and turbine room, the building would only have to enclose the switchgear at generating voltage.

As with the indoor scheme, the circuit centres on the outdoor arrangements would be controlled by the transformers, the overall length of the two schemes being the same. Sectional elevation drawings will, therefore, serve to give a proper comparison between the actual layout and the possible alternatives.

In the first case, on the assumption that ground area is not of particular importance, all apparatus has been shown on ground level—Fig. 7. The equipment included is precisely the same as with the indoor scheme, with the exception that separate isolators for the electrolytic arresters have been omitted as unnecessary.

The steelwork required is quite simple. Double-tower structures, as shown, would be placed between every three circuits, the towers being tied together only by the horizontal I beams run to support the busbar isolating switches, which are operated from ground level as three-pole units. It is very unlikely that any access will be required to the isolating switches, and there is no need to run handrails or footwalks out to them. In all cases the connections are arranged so that, with the switches open, the hinge element, which houses the blade-lifting mechanism, is dead. The busbars themselves are strained between the tower structures, the various lengths being connected by bus-sectionalising isolating switches.

Unusual Method of Straining-off.

The method of straining-off the transmission lines is a little unusual. A steel cable is run between the tower structures and the link-type strain insulators fastened to this. It is more usual to provide a rigid support in the form of a horizontal, lattice-member spanning from tower to tower. This arrangement facilitates straining the lines when erecting, but is, of course, appreciably more expensive. The choice between these two methods depends mainly on the position of the first tower, since, if the line tension on the switch structure is considerable, the rigid construction would be preferable.

The choke coil is built around a strain insulator, and may safely be inserted in the length of the transmission line itself. Electrically, it is equally effective, and it is somewhat easier to erect, if it is suspended in the length of the jumper which goes to the feeder isolating switch, in the manner shown in the illustration.

Since this equipment would be placed immediately adjacent to the power-house building, no special structure is required for the star-point connection on the H.-T. side of the transformers. A light, steel cantilever built out from the wall would support the insulators carrying this connection.

For handling the single-phase transformer units a transfer truck, similar to that used on the indoor scheme, would be provided. In this way any transformer in need of attention could be transported bodily into the power-house workshop. The pipe-work for cooling water, and for oil drainage, together with the low-tension cable connections, are brought to that side of the transformer remote from the track, so as not to interfere with removal.

When horned arresters are placed out of doors greater clearance has to be given, to allow for the effect of wind on the arc. This is sometimes the controlling factor which determines the height of the main structure, since the transmission lines must be carried well clear of the horns beneath.

Position of the Tanks.

The tanks containing the aluminium trays are the only portion of this equipment which may be at high potential, and which are accessible from the ground. On the assumption that only skilled operators will ever be inside the h.t. switchyard, it is not usual to do more than put a handrail round the tanks, so as to prevent accidental contact, and quite often even this is omitted.

With the high-tension apparatus arranged as Fig. 7, the total space occupied by the whole plant would be 220 ft. by 166 ft. The transformers and outdoor switchgear would occupy 220 ft. by 96 ft., and would require some 26 tons of structural steelwork. There is no real need for the whole ground area to be concreted, if small plinths are made for each piece of apparatus and proper footings for the towers. Assuming, however, that the full area is covered with 3 in. concrete lying on 9 in. rubble, the present-day cost of concrete and steel would be about £2 300, if erected in this country.

The power-house buildings necessary have been estimated at £20 000 present-day prices (roughly, 7·25d. per cub. ft.). The switchgear and transformers would be worth, say, £64 700, giving for the items which vary with the switchgear arrangement a total of £87 000.

Against this for the fully indoor scheme, shown in Fig. 6, we have an estimated building cost of £45 000 (6·3d. per cub. ft.). The difference between indoor and outdoor apparatus, erected, is not so marked at the higher voltages, and the current price of the indoor gear would be £61 570, giving a total of £106 570. The total space occupied by this plant would be 220 ft. by 124 ft.

A More Economical Arrangement.

Another outdoor arrangement which might be adopted is shown in Fig. 8. This is considerably more economical

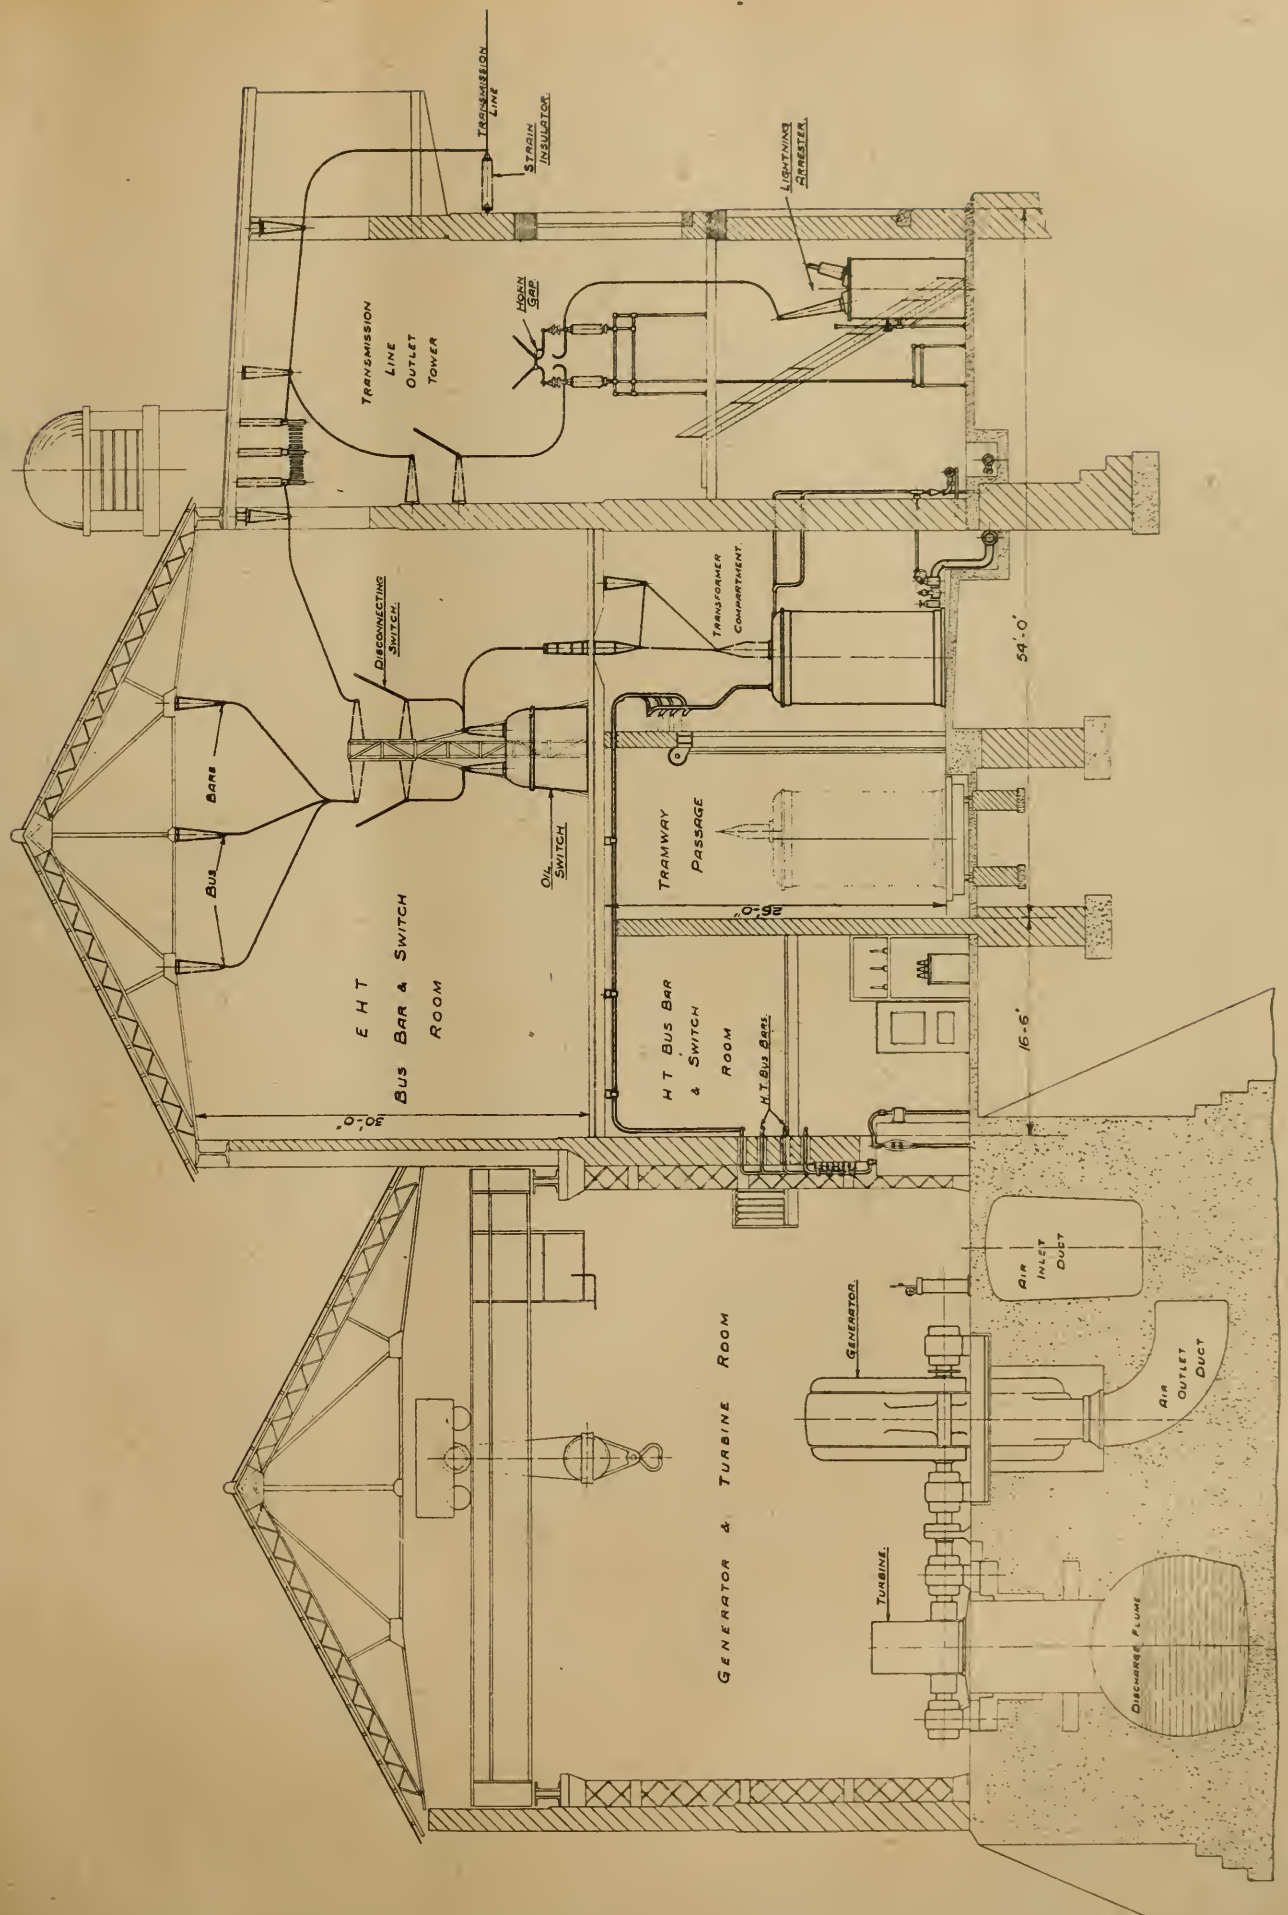

Fig. 6.—Sectional Elevation of Power House (J. Tata Hydro-Electric Company, Ltd., Bombay).

in the matter of space occupied, but to some extent open to the accusation of being "a forest of steel." This impression is very easily gained from pictures of outdoor stations, particularly by those who have not seen the actual structures, but it is nearly always a matter of the angle from which the photograph was taken.

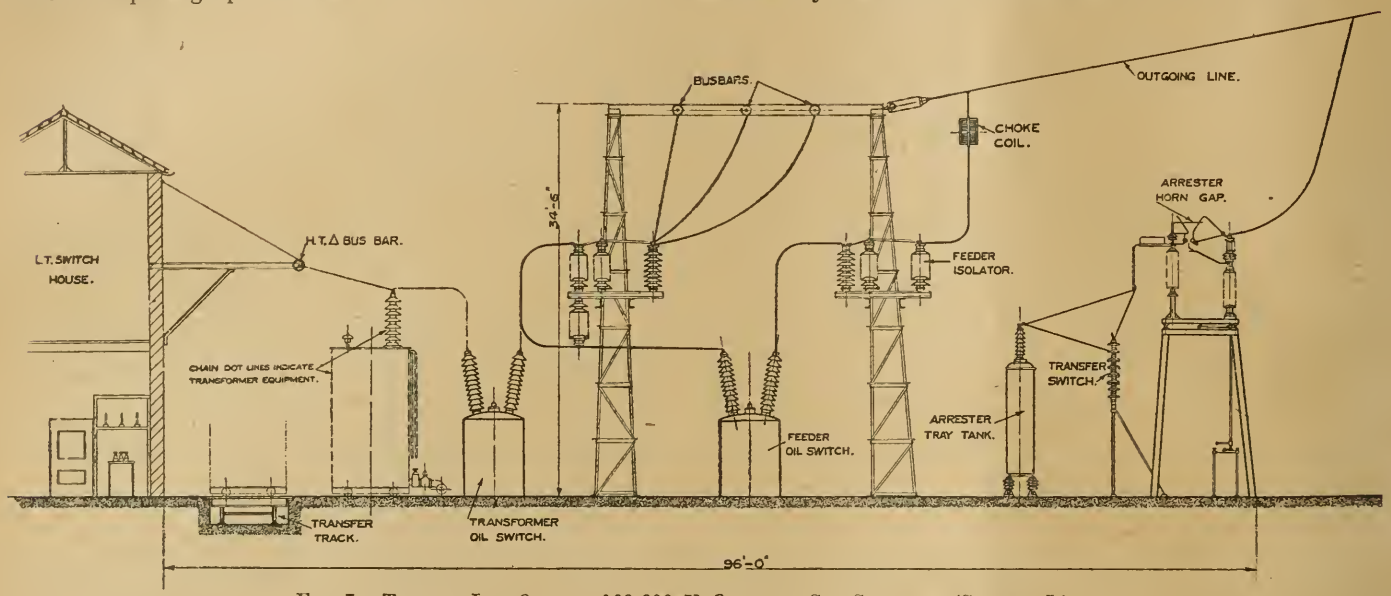

FIG. 7.—TYPICAL LAY-OUT OF 100 000 V OUTDOOR SUB-STATION. (SCHEME I.)

It will be recalled that there is only one outgoing line to every three circuits. It would thus be quite feasible to space out the lines sufficiently to permit other conductors to pass them. This is done, the horns of the lightning arresters being placed right at the top, where, incidentally, they are entirely removed from any risk of trouble due to a flaring arc. The transfer switches are placed half-way down, and the tanks on ground level. The method of supporting the vertical connections is noteworthy. Multiple shed insulators are much better in tension or compression than when mounted with their axes horizontal. Stub connections are, therefore, strained between insulators top and bottom, and jumpers taken to them from the trays and transfer-switch. Similarly, just below the fuse of the arrester, the connection is steadied between insulators strained by steel cables off the steelwork.

Charging operations would be carried out from the platform on the same level as, but on one side of, the transfer-switch, the operating levers for the gap-shortening device and the transfer-switch being brought down to this point.

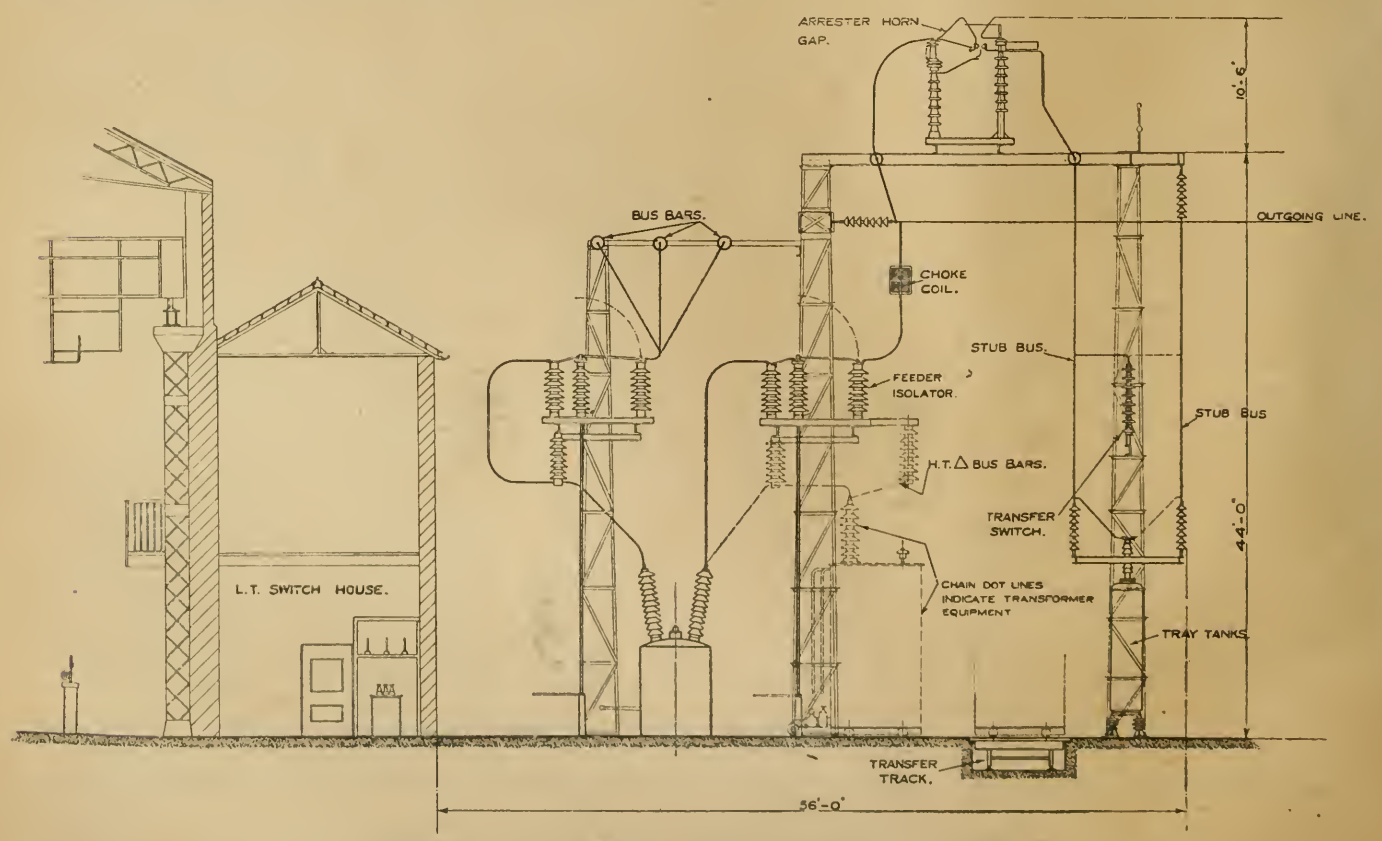

FIG. 8.—TYPICAL LAY-OUT OF 100 000 V OUTDOOR SUB-STATION. (SCHEME II.)

To facilitate renewal of fuses, a footwalk and handrail is shown on the top of the structure, a ladder up the tower giving access.

In this case the area occupied by the whole plant would only be 220 ft. by 126 ft., and by the outdoor gear 220 ft.

by 56 ft., but the outdoor steelwork goes up to 54 tons. The complete cost of the scheme, on the same basis as previously, works out at approximately £88 000.

The Power-House Roof as Switch-Yard.

Still another possibility, and one which has been quite frequently adopted, is that of putting all high-voltage switchgear on the power-house roof, as in Fig. 9. This takes up less ground space than the indoor scheme actually employed. No special comments need be made on the lay-out suggested, since the notes on previous schemes apply with equal force here.

That portion of the building which is retained is considerably more expensive than the corresponding section of the all-indoor building, since the roof has to be strong enough to carry the switchgear, and all the main walls must be stiffened right down to the foundations to bear the extra load.

A rough estimate places the cost of building at £22 000 where the power-house stands on the dam itself, or even in some city terminal stations, ground space considerations alone will often justify this construction.

The following table summarises the points for comparison in the various schemes:

Fig. No.	Brief description of H.T. equipment.	Sq. feet occupied by complete plant.	Approximate costs.			Total cost of variants.
			Switchgear and Transformers.	Outdoor structure and concrete	Building.	
6	All indoors ...	27,280	£61,570	—	£45,000	£106,570
7	Outdoor simple structure ...	36,520	£64,700	£2,300	£20,000	£87,000
8	Outdoor: two tier structure ...	27,720	£65,800	£2,200	£20,000	£88,000
9	Outdoor on roof ...	21,120	£65,800	£1,000	£22,000	£88,800

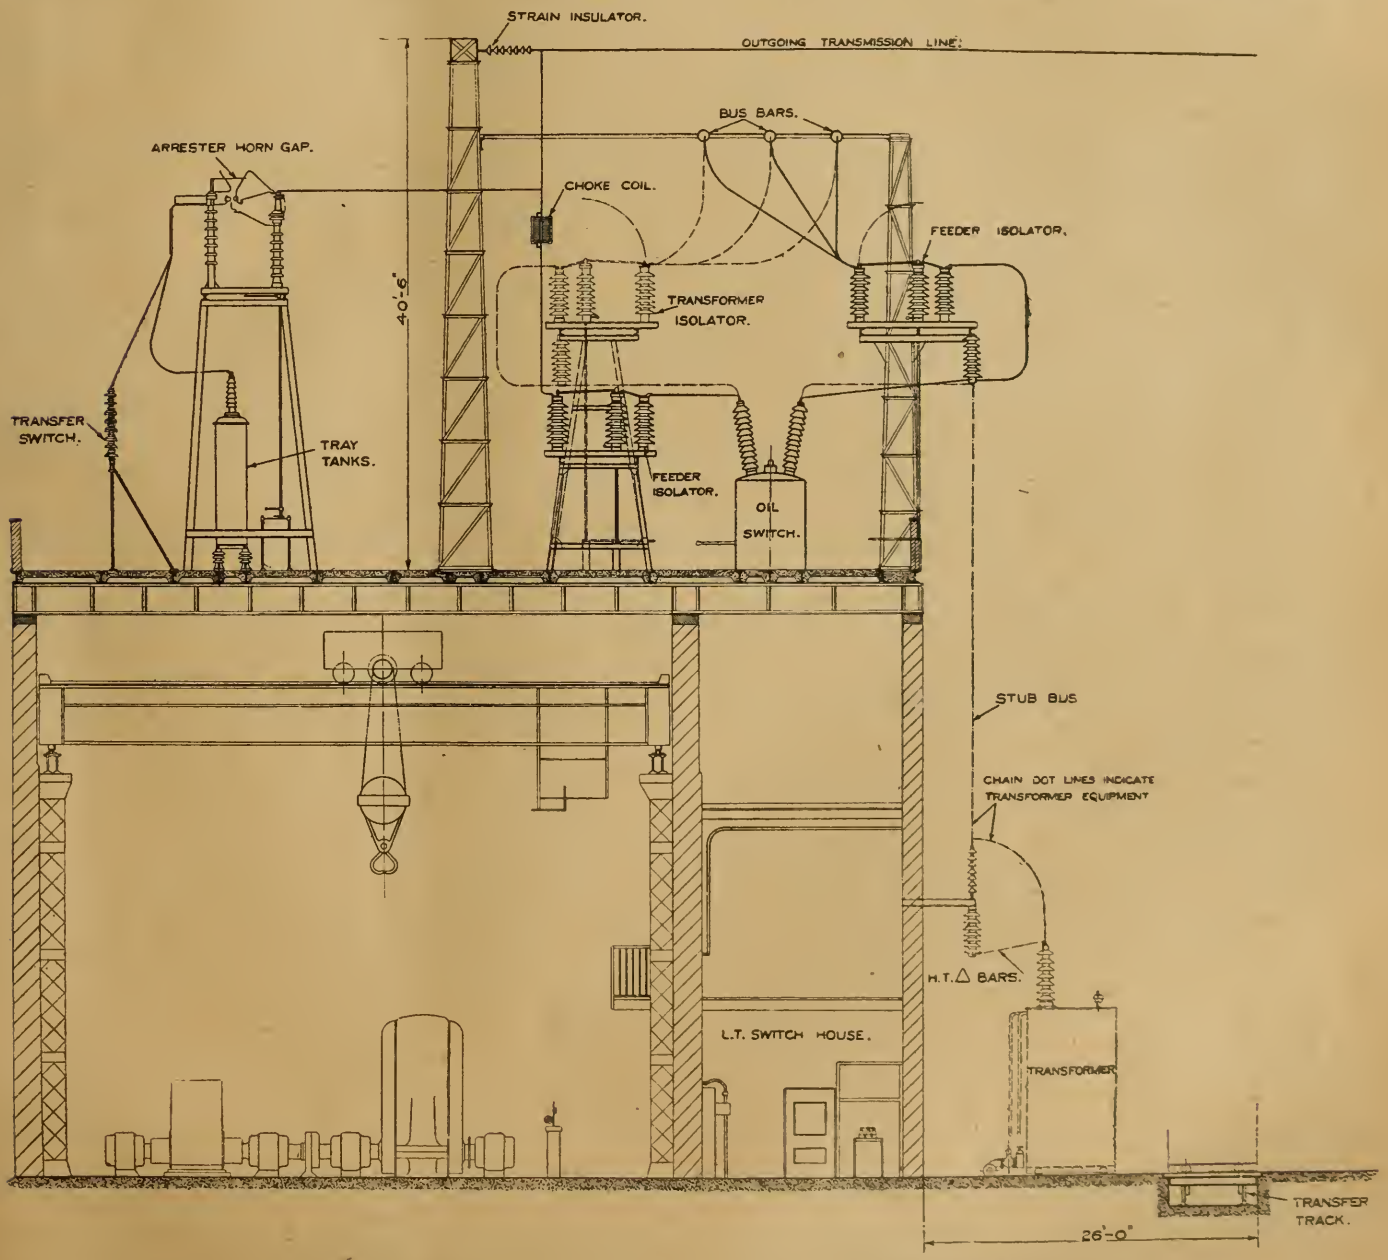

Fig. 9.—Typical Lay-Out of 100 000 V Outdoor Sub-Station. (Scheme III.)

(8d. per cub. ft.), which, with the price of transformers and switchgear, gives a total (comparable with those given for other schemes) of £88 800.

It will be seen that on cost, apart from ground space, this arrangement is the least favourable of the outdoor schemes. In the case of a low or medium head hydro-electric station,

It is impossible to set down in writing the whole case for the outdoor station. It is submitted that enough has been said to make it clear that outdoor construction has not only come to stay, but that in the end it will probably oust completely the use of buildings for high-voltage switchgear and transformers, save only in exceptional cases.

Chains of Magnetically-Coupled Circuits.

By E. BELLINI, D.Sc.

In an article recently published in this journal * the frequencies occurring in three magnetically-coupled circuits were mathematically determined and shown to be practically verified by experiments.

In the present article the cases of four and five magnetically-coupled circuits will be solved, and attempts to solve the problem of six and seven circuits will be made. From the results obtained some general rules for an indefinite number of magnetically-coupled circuits will be deduced.

A chain of magnetically-coupled circuits is shown in Fig. 1. Each circuit is magnetically coupled to the preceding and to

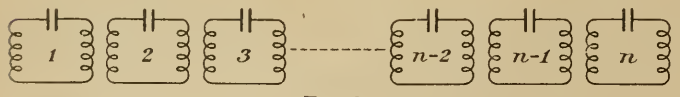

FIG. 1.

the following ones, the first and last circuits being coupled only to one circuit.

The method adopted for the calculations is the method of operational determinant suggested by Mr. L. C. Pocock in a letter† published on the occasion of the publication of the article above cited.

As in the former article, it will be presumed in what follows that the ohmic resistances of the coupled circuits are zero and that all the circuits possess the same inductances and capacities.

Four Magnetically-Coupled Circuits.

The operational determinant in this case is :

$$\begin{vmatrix} \frac{1}{C}-Lp^2 & -M_{12}p^2 & 0 & 0 \\ -M_{12}p^2 & \frac{1}{C}-Lp^2 & -M_{23}p^2 & 0 \\ 0 & -M_{23}p^2 & \frac{1}{C}-Lp^2 & -M_{34}p^2 \\ 0 & 0 & -M_{34}p^2 & \frac{1}{C}-Lp^2 \end{vmatrix} = 0$$

Multiplying out this determinant one obtains

$$\left(\frac{1}{C}-Lp^2\right)^4-\left(\frac{1}{C}-Lp^2\right)^2(M_{12}^2+M_{23}^2+M_{34}^2)p^4+M_{12}^2M_{34}^2p^8=0$$

In order to find the roots of this equation let us put in it $p=\frac{1}{\sqrt{LC}(1+a)}$; we obtain

$$a^4-a^2(K_{12}^2+K_{23}^2+K_{34}^2)+K_{12}^2K_{34}^2=0$$

where $K_{12}=\frac{M_{12}}{L}$, $K_{23}=\frac{M_{23}}{L}$ and $K_{34}=\frac{M_{34}}{L}$.

By solving this equation with respect to a we obtain

$$a=\pm\frac{1}{\sqrt{2}}\sqrt{K_{12}^2+K_{23}^2+K_{34}^2\pm\sqrt{(K_{12}^2+K_{23}^2+K_{34}^2)^2-4K_{12}^2K_{34}^2}}.$$

Hence, the four periodicities of a chain of four magnetically-coupled circuits are :

$$p_1, p_2, p_3, p_4=\frac{1}{\sqrt{LC}}\cdot\frac{1}{\sqrt{1\pm\frac{1}{\sqrt{2}}\sqrt{K_{12}^2+K_{23}^2+K_{34}^2\pm\sqrt{(K_{12}^2+K_{23}^2+K_{34}^2)^2-4K_{12}^2K_{34}^2}}}}$$

In the particular case of $K_{12}^2=K_{23}^2=K_{34}^2=K^2$ the four periodicities are :

$$p_1, p_2, p_3, p_4=\frac{1}{\sqrt{LC}}\cdot\frac{1}{\sqrt{1\pm K\sqrt{\frac{3\pm\sqrt{5}}{2}}}}$$

* THE ELECTRICIAN, July 16, 1920.
† THE ELECTRICIAN, Aug. 6, 1920.

Three- and Four-Coupled Circuits Compared.

In the case of three magnetically-coupled circuits it was found that, though three frequencies existed in the system of circuits considered as a whole, only two frequencies existed in the central circuit. This fact must logically lead us to verify if all the four circuits in the present case possess four frequencies. This verification can be accomplished by employing the above operational determinant in which the values of C and L for each circuit in turn will be made different from those of the other circuits, by multiplying it out and by verifying if the equation so obtained is confirmed by the four periodicities found. If one or more periodicities were found to confirm this equation, it would mean that in this particular circuit the periodicity or periodicities considered do not occur and that the timing of this circuit has no influence upon the existence of these periodicities in the other circuits.

To simplify the calculations, it is convenient to suppose all the M equal, as the values of the M (except in the extreme case of one or more of them being equal to zero) cannot have any influence upon the existence of the frequencies.

If we apply this method to the actual case of four magnetically-coupled circuits, we can find that the timing of the four circuits is necessary for obtaining the four frequencies, and we can infer, then, that the four periodicities exist in each of the four circuits.

Five Magnetically-Coupled Circuits.

By multiplying out the operational determinant in this case we obtain an equation of the fifth degree :

$$\left(\frac{1}{C}-Lp^2\right)^5-p^4\left(\frac{1}{C}-Lp^2\right)^3(M_{12}^2+M_{23}^2+M_{34}^2+M_{45}^2)+p^8\left(\frac{1}{C}-Lp^2\right)(M_{12}^2M_{34}^2+M_{23}^2M_{45}^2+M_{45}^2M_{12}^2)=0$$

It is immediately obvious that $p=\frac{1}{\sqrt{LC}}$ is a root of the equation.

By dividing the equation for $\left(\frac{1}{C}-Lp^2\right)$ it becomes :

$$\left(\frac{1}{C}-Lp^2\right)^4-p^4\left(\frac{1}{C}-Lp^2\right)^2(M_{12}^2+M_{23}^2+M_{34}^2+M_{45}^2)+p^8(M_{12}^2M_{34}^2+M_{23}^2M_{45}^2+M_{45}^2M_{12}^2)=0$$

To solve this equation let us put in it $p=\frac{1}{\sqrt{LC}(1+a)}$. We obtain :

$$a^4-a^2(K_{12}^2+K_{23}^2+K_{34}^2+K_{45}^2)+K_{12}^2K_{34}^2+K_{23}^2K_{45}^2+K_{45}^2K_{12}^2=0$$

from which we draw out :

$$2a^2=K_{12}^2+K_{23}^2+K_{34}^2+K_{45}^2\pm\sqrt{(K_{12}^2+K_{23}^2+K_{34}^2+K_{45}^2)^2-4(K_{12}^2K_{34}^2+K_{23}^2K_{45}^2+K_{45}^2K_{12}^2)}$$

The five periodicities of five magnetically-coupled circuits are, consequently

$$p_1=\frac{1}{\sqrt{LC}}$$

$$p_2, p_3, p_4, p_5=\frac{1}{\sqrt{LC}}\cdot\frac{1}{\sqrt{1\pm\frac{1}{\sqrt{2}}\sqrt{K_{12}^2+K_{23}^2+K_{34}^2+K_{45}^2\pm\sqrt{(K_{12}^2+K_{23}^2+K_{34}^2+K_{45}^2)^2-4(K_{12}^2K_{34}^2+K_{23}^2K_{45}^2+K_{45}^2K_{12}^2)}}}}$$

In the particular case of $K_{12}^2=K_{23}^2=K_{34}^2=K_{45}^2=K^2$ the five periodicities are :

$$\frac{1}{\sqrt{LC}}, \frac{1}{\sqrt{LC(1+K)}}, \frac{1}{\sqrt{LC(1-K)}}, \frac{1}{\sqrt{LC(1+\sqrt{3}K)}}, \frac{1}{\sqrt{LC(1-\sqrt{3}K)}}.$$

It is interesting to note that five equal and equally magnetically-coupled circuits possess the frequency of each

circuit separately and those of two of these circuits magnetically coupled.

By applying the method described for the case of four circuits we obtain that:

(1) the periodicity $\frac{1}{\sqrt{LC}}$ exists in the circuits 1, 3, and 5 and not in the circuits 2 and 4.

(2) The periodicities $\frac{1}{\sqrt{LC(1\pm K)}}$ exist in the circuits 1, 2, 4 and 5 and not in the circuit 3.

(3) The periodicities $\frac{1}{\sqrt{LC(1\pm\sqrt{3}K)}}$ exist in all the circuits.

Six Magnetically-Coupled Circuits.

By multiplying out the operational determinant in this case we obtain:

$$\left(\frac{1}{C}-Lp^2\right)^6-p^4\left(\frac{1}{C}-Lp^2\right)^4(M_{12}^2+M_{23}^2+M_{34}^2+M_{45}^2+M_{56}^2)+$$
$$p^8\left(\frac{1}{C}-Lp^2\right)^2(M_{12}^2M_{34}^2+M_{23}^2M_{45}^2+M_{34}^2M_{56}^2+M_{45}^2M_{12}^2+M_{56}^2M_{23}^2+$$
$$M_{56}^2M_{12}^2)-p^{12}M_{12}^2M_{34}^2M_{56}^2=0.$$

It was impossible to solve this equation. It shows, however, that six frequencies exist in the system of six magnetically-coupled circuits, and that the common natural frequency of the circuits is not comprised among them.

Seven Magnetically-Coupled Circuits.

The operational determinant in this case, when multiplied out, furnishes the following equation:

$$\left(\frac{1}{C}-Lp^2\right)^7-\left(\frac{1}{C}-Lp^2\right)^5p^4(M_{12}^2+M_{23}^2+M_{34}^2+M_{45}^2+M_{56}^2+M_{67}^2)+$$
$$\left(\frac{1}{C}-Lp^2\right)^3p^8(M_{12}^2M_{34}^2+M_{12}^2M_{45}^2+M_{12}^2M_{56}^2+M_{12}^2M_{67}^2+M_{23}^2M_{45}^2+M_{23}^2$$
$$M_{56}^2+M_{23}^2M_{67}^2+M_{34}^2M_{56}^2+M_{34}^2M_{67}^2+M_{45}^2M_{67}^2)-\left(\frac{1}{C}-Lp^2\right)p^{12}(M_{12}^2M_{34}^2$$
$$M_{56}^2+M_{23}^2M_{45}^2M_{67}^2+M_{12}^2M_{34}^2M_{67}^2+M_{12}^2M_{45}^2M_{67}^2)=0$$

It is immediately visible that the fundamental periodicity $\frac{1}{\sqrt{LC}}$ is a root of the equation.

If all the M are equal the equation, divided for $\left(\frac{1}{C}-Lp^2\right)$ simplifies to

$$\left(\frac{1}{C}-Lp^2\right)^6-6p^4\left(\frac{1}{C}-Lp^2\right)^4M^2+10p^8\left(\frac{1}{C}-Lp^2\right)^2M^4-4p^{12}M^6=0$$

It was not possible to solve these equations. But it can be verified by substitution that

$p_2p_3=\frac{1}{\sqrt{LC(1\pm\sqrt{2})K}}$ are two roots of the latter.

It is worth while to note that seven equal and equally magnetically-coupled circuits possess the frequency of each circuit separately, and those of three of these circuits magnetically coupled (which, in their turn, possess the first frequency).

Summary for the Case of Equality of all the Coupling Coefficients.

1 circuit	$\frac{1}{\sqrt{LC}}$
2 circuits	$\frac{1}{\sqrt{LC(1\pm K)}}$ in both circuits.
3 circuits	$\frac{1}{\sqrt{LC}}$ only in the end circuits
	$\frac{1}{\sqrt{LC(1\pm\sqrt{2}K)}}$ in all circuits
4 circuits	$\frac{1}{\sqrt{LC(1\pm K\sqrt{\frac{3\pm\sqrt{5}}{2}})}}$ in all circuits
5 circuits	$\frac{1}{\sqrt{LC}}$ in circuits 1, 3, and 5
	$\frac{1}{\sqrt{LC(1\pm K)}}$ in circuits 1, 2, 4, and 5
	$\frac{1}{\sqrt{LC(1\pm\sqrt{3}K)}}$ in all circuits
6 circuits	.. ..
7 circuits	$\frac{1}{\sqrt{LC}}$, $\frac{1}{\sqrt{LC(1\pm\sqrt{2}K)}}$, ...

Conclusions.

From the arguments set out it appears justifiable to draw the following conclusions:

(1) The number of resultant frequencies of n magnetically-coupled circuits is n.

(2) When the number of coupled circuits is even all the resultant frequencies are present in all the circuits.

(3) When the number of coupled circuits is odd, only the end circuits have all the resultant frequencies; circuits 2 and $n-1$ have $n-1$ frequencies; circuits 3 and $n-2$ have $n-2$ frequencies, &c., so that the middle circuits have only $\frac{n+1}{2}$ frequencies.

(4) When the number of coupled circuits is odd, only the circuits numbered 1, 3, 5, . . . $(n-4)$, $(n-2)$, n possess the natural frequency of each circuit separately.

(5) The frequencies proper to n equal and equally magnetically-coupled circuits exist in a chain of $2n+1$ magnetically coupled circuits.

Correspondence.

DOMESTIC ELECTRICAL APPLIANCES.

To the Editor of THE ELECTRICIAN.

SIR,—We feel that that section of the electrical industry which is in closest touch with the general public, *i.e.*, the electrical contractor and retailer, should be made aware of the endeavours that are being made in another industry to secure a portion, if not all, of the business to be done in the above.

The official organ of the retailers of sewing and washing machines and carpet sweepers is continually advising its readers to take up these lines.

The following passage is taken from the said journal, dated May 1:

"We will only add that the daily Press is creating a demand for sewing and washing machines and carpet cleaners, and that it is for the domestic washing trade to supply the demand and not leave it to the electrical trade."

Our own practice has, of course, been to treat with the legitimate electrical trader, but we think you should impress on your readers the great danger they are in of losing a good portion of what is proving a very lucrative and growing field.—I am, &c.,

THE SUN ELECTRICAL COMPANY
(E. R. Norton, Works Manager).

London, W.C. 2, May 6.

AN ANOMALY.

To the Editor of THE ELECTRICIAN.

SIR,—The following should, I think, be placed on record in all electrical papers:

The headquarters of the Electricity Commissioners is Gwydyr House, Whitehall, a board on the door announcing this fact. I was passing the place last Friday, and first noticed that the lamp over the gate is fitted with an upright incandescent gas mantle; further investigation resulted in finding two large cone-shaped candle or torch snuffers, one on each side of the gateway on the railings. Further, a notice is on the door stating that admittance can be obtained by ringing the bell, which is one of the old-fashioned brass knob crank bells. The place was closed, but it would be interesting to know whether gas is used for lighting the interior as it is for the outside lamp.—I am, &c.,

WILLIAM B. CLARKE.

Ponders End, Middlesex, May 8.

The History of the Spearing Boiler.

Although the water-tube boiler came into being more than half a century ago, it is only within the last twenty years or so that it has been extensively used, and to a large extent its adoption was the result of engineering developments peculiar to recent times. The growth of electric power stations, the increase in the speed and size of steamships—these and kindred conditions created a demand for boilers more flexible, more efficient, and of greater capacity than the traditional types. In turn, the success of the water-tube principle encouraged engineers to make further demands upon it, in order to obtain still higher thermal efficiencies. Hence the movement towards higher steam pressures and higher superheat. Since the war, owing to the heavier cost of fuel, labour, and materials, the need for boiler efficiency has become more and more insistent. The water-tube boiler of to-day has, it will be agreed, to fulfil requirements much more onerous and exacting than those formerly imposed.

An Established Boiler.

The Spearing boiler has been designed to meet these conditions in the highest degree, compatible with economy in first cost and maintenance charges. But it is not, in its essential features, a new boiler. The principles upon which it is constructed were put to the test about twelve years ago; and their soundness has been proved by the continuous existence in satisfactory service of boilers then built. Improvements have been embodied from time to time, partly as the result of accumulated experience and partly in response to the evolution of steam engineering in the directions indicated; and to-day it is claimed that the boiler has proved its ability to meet the most exacting requirements. The chief interest in the present stage of the Spearing enterprise lies in the arrangements which are being made to establish manufacture on an adequate scale. A controlling interest in Tinkers, Ltd., an old-established firm of boiler makers at Hyde, near Manchester, has been acquired and the works will shortly be enlarged to double their former capacity.

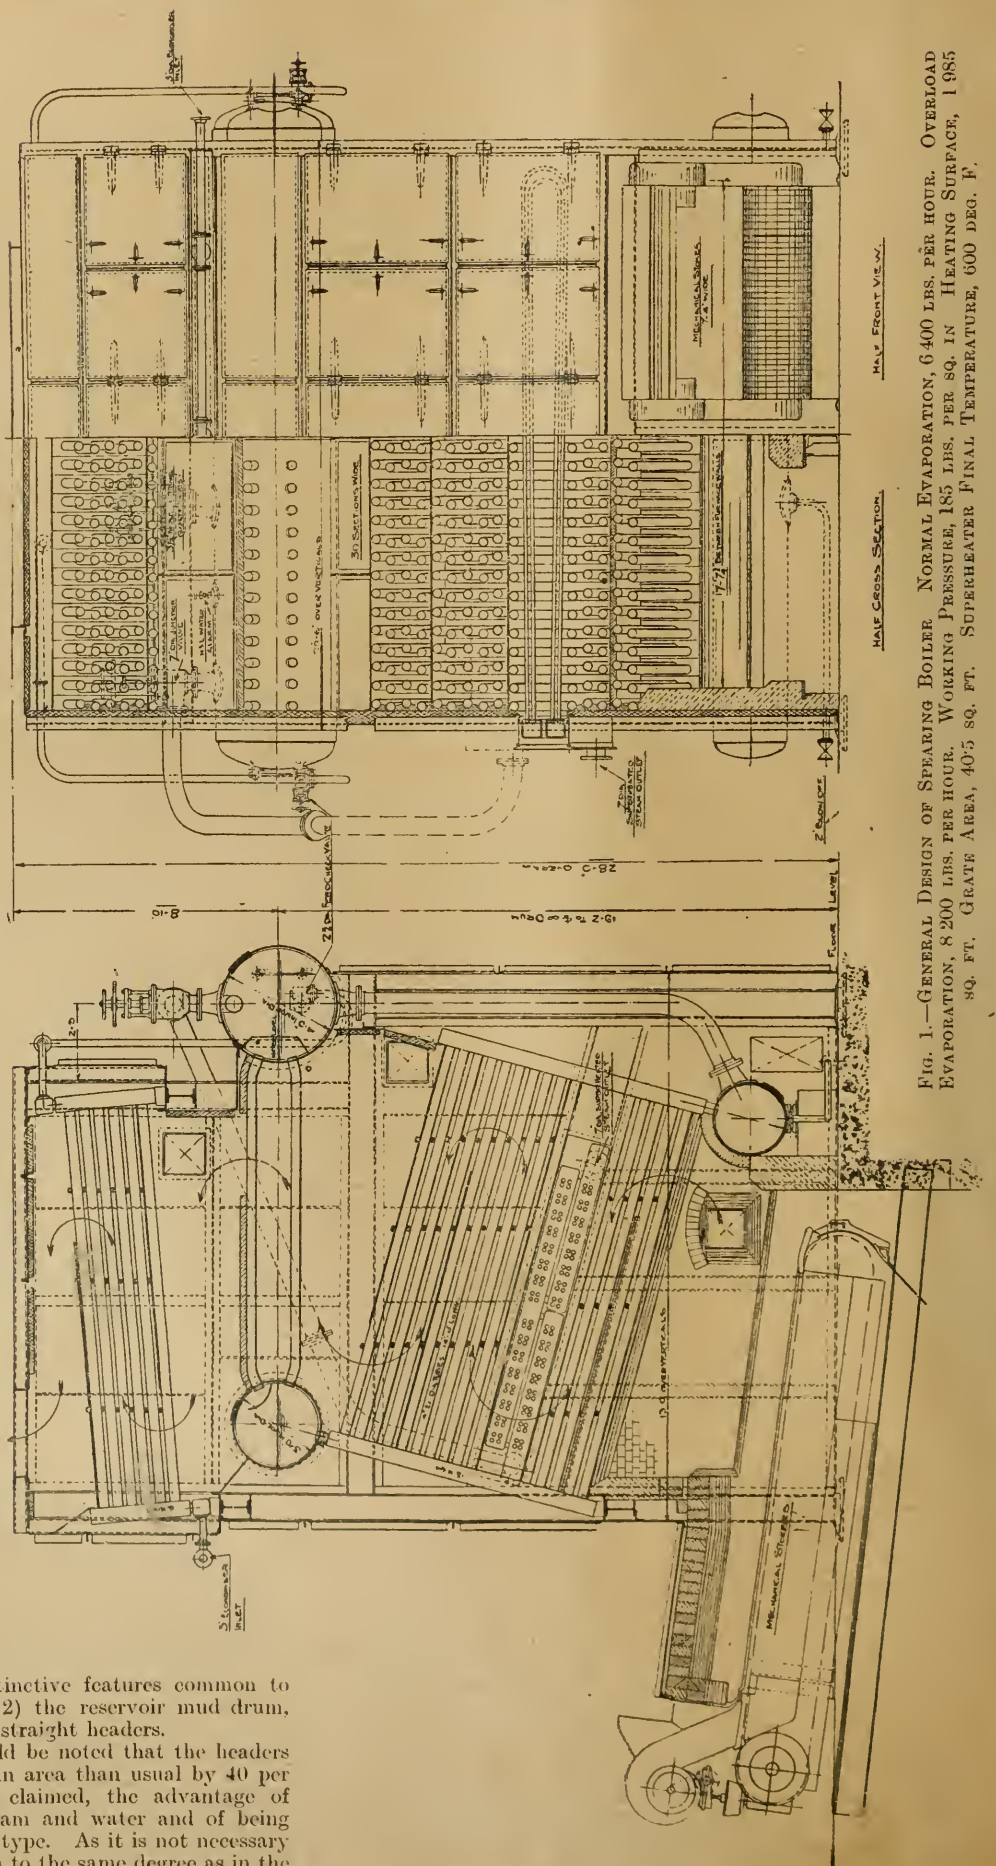

Fig. 1.—General Design of Spearing Boiler. Normal Evaporation, 6 400 lbs. per hour. Overload Evaporation, 8 200 lbs. per hour. Working Pressure, 185 lbs. per sq. in. Heating Surface, 1 985 sq. ft. Grate Area, 405 sq. ft. Superheater Final Temperature, 600 deg. F.

The Two Types of Spearing Boiler.

It may be mentioned that there are two types of Spearing boiler, the first with a longitudinal drum and the second with a cross drum. The first type is adopted for smaller sizes and the latter for boilers of larger capacity. Both are of the sectional header class; and the distinctive features common to both are: (1) the downcomer pipes, (2) the reservoir mud drum, (3) the enlarged nipples, and (4) the straight headers.

Taking the last point first, it should be noted that the headers are straight, rectangular, and larger in area than usual by 40 per cent. Straight headers have, it is claimed, the advantage of affording freer circulation to the steam and water and of being more easily cleaned than the sinuous type. As it is not necessary to stretch the material in construction to the same degree as in the sinuous headers, the thickness of the straight headers is more

uniform. Further, it is a simpler matter to make the joints between the straight headers airtight. The headers are connected to the drums by nipple tubes which are 28 per cent. larger in area than is usually the case—a feature which increases the safe and steady steaming capacity of the boiler.

The Downcomer Pipes.

The reservoir mud drum has to be considered in connection with the downcomer pipe which leads to it from the circulation drum. The function of this pipe—one, two or more are fitted according to the evaporative capacity of the boiler—is to secure positive circulation from the main steam and water drum through the mud drum to the headers and tubes. Usually the internal diameter of the downcomer pipe is about 8 in., so that the risk of choking by deposit or incrustation is altogether negligible. In the position it occupies it is not subjected to excessive temperature. Each pipe is solid drawn, and is flanged at each end so that it may be bolted to stand pipes riveted to the steam drum and mud drum respectively. This arrangement enables the downcomer pipe to be readily detached if necessary.

Efficient Circulation.

By means of the downcomer pipe all the water is circulated through the mud drum, which efficiently collects and retains deposit which would otherwise be distributed through the headers or on the steam generating surfaces. The mud drum is of ample size and is easily accessible for cleaning. The water flows from it through short connecting nipples to the back headers; and a glance (Fig. 1) at the general design of the boiler will show that this arrangement provides a full supply of water to the bottom rows of tubes first. Again, the flow is in the right direction along the tube—upward and onward. As the tubes nearer the fire play the larger part in steam generation, the correct mode of water supply is of great importance.. It is claimed that the Spearing boiler (Fig. 1) surpasses other water-tube boilers in this connection, and it has been successful in the case of oil firing, the freedom from blistering of the tubes due to the positive supply of water to the bottom rows of tubes being very marked.

In the longitudinal drum type the headers are connected to the drum by curved nipples directly expanded into holes in the drum. These holes are compensated for by a doubling plate, thus avoiding the weakness of a cross-box with a large opening in the shell and a considerable flat surface. In the Spearing boiler the water tubes are staggered about 1 in., but no claim is made that the arrangement adds anything to the efficiency of the boiler. The advantage of the relatively small stagger is that it facilitates the removal of soot by blowers.

Circulation Advantages.

One outstanding result of the general design of the Spearing boiler, with large downcomer pipe, the large nipples, and straight headers, is that a free, natural and positive circulation is secured. This feature, combined with the ample steam and water capacity, enables the boiler to respond readily to overload demands. The renewal and the cleaning of tubes are not only exceptionally simple, on account of the tubes being straight and easy of access, but the necessity for either is reduced by the peculiarities of circulation mentioned above. Expansion and contraction stresses are also minimised, as all parts liable to considerable changes in dimensions are free to adjust themselves to an unusual degree. A general view of the boiler is given in Fig. 2.

Fig. 2.—General Assembly of the Spearing Boiler.

Street Lighting in the United States.*

The evolution of electric street lighting in all countries has necessarily been dependent on the development of dynamo-electric machinery. The electric arc lamp reached a fairly advanced stage at a time when the distribution of electricity was in its infancy. The City of Paris, in years prior to 1878, had made lavish use of gas light (according to the standard of that time), and the exhibition of the now obsolete Jablochkoff candle for the illumination of the Avenue de l'Opéra in that year attracted much interest and may be said to mark the initiation of the use of arc lamps for street lighting. The decade from 1880 to 1890 was signalised by the development of series arc lighting stations, mainly using the Brush and Thomson-Houston plant, about 50 to 75 arcs on a 10 A constant current system being used. The Thomson-Houston dynamo had peculiar features and attracted much attention at the Inventions Exhibition in London in 1885, where electricians, on seeing the dynamo-connections declared "It can't work, but it does!"

Arc Lamp Progress.

Before 1890 street lighting with arc lamps had made considerable progress, which was aided by the few restrictions then placed on the use of overhead high-tension wires. The first notable change was the reduction of the current to 6·8 A, with a corresponding increase in the number of lamps that could be run with a given energy-consumption. Enclosed arcs subsequently replaced open arcs in many cases, owing to the longer life of the carbons, but the efficiency of light-production with alternating current was very low. The development of flame arcs, luminous ("magnetite") arcs and incandescent lamps of progressively higher candle-power and efficiency has created an interesting situation, and to-day it is scarcely possible to predict which will finally "win out." In the United States one feature of street lighting that differs materially from conditions in this country is the general use of series constant-current circuits. This system is most common both for arc and incandescent lamps, though there are large multiple systems in operation—notably in New York, where the limitation of the pressure to a low value is considered an advantage. Series systems, as a rule, do not use a total voltage in excess of 5000 V, but insulation must withstand at least twice that voltage, as an earth on any part of the line may increase the voltage by 50 to 100 per cent.

Many installations are carried overhead, but the necessity for a safe and inexpensive earth system in cities and for parks, playgrounds, &c., has led to the development of steel tape cable, which can be laid direct in the ground at a comparatively small depth, being frostproof and waterproof.

Gasfilled *v.* Magnetic Lamps.

It would appear that the two lamps most favoured for street lighting are gasfilled incandescent lamps and luminous, or magnetite, arc lamps. For gasfilled lamps, as well as arcs, the series lamp is still the standard, and types taking 6·6 A, 15 A and 20 A are in

* Based on a series of articles in the "General Electric Review."

common use. With such relatively high currents, strong filaments and good conditions as regards life and efficiency can doubtless be obtained. Thus the 20 A lamps are credited with 19·3 lumens per watt, which is equivalent to about 0·66 W per mean spherical candle-power—probably within half a watt per rated candle-power. It is recognised, however, that rating in terms of candle-power in one direction is unsatisfactory. Lamps are now rated in lumens; what was formerly a 400 c.p. lamp, for example, being now regarded as 4 000 lumens (the product of the "reduction factor" and 4 A being approximately 10). It is stated that for typical street lamps the depreciation should not exceed 10 per cent. over a natural life of 1 350 hours; some companies replace all lamps that have burned for 1 500 hours. Naturally the use of high-tension series systems makes the series lighting transformer an important piece of apparatus, and various models are described in the original articles. Another essential piece of apparatus, also illustrated in detail, is the cut-out, which is described as the safety valve of the a.c. series system, and which automatically short-circuits any lamp that fails.

Details of the Magnetite Lamp.

The "luminous" or magnetite arc lamp was first put into operation in 19·3, and is still used in most of the larger cities of the United States. It will be recalled that in this lamp, which is little known in England, the upper electrode consists of a rod of solid copper, which is relatively non-consuming, and may last for 2 000-6 000 hours. The nature and efficiency of the light is determined by the lower electrode, which has been the subject of much study. A mixture of titanium oxide with magnetite, together with a small amount of chromium oxide to give added steadiness, is now commonly used. It appears that the life of this lower electrode, which furnishes the stream of luminous vapour, is about 150 to 200 hours, but depends on the material. A high efficiency (17 to 25 lumens per W) involves some sacrifice of life; with the long-life electrodes 11 to 18 lumens per watt is aimed at. It is stated that the slight motion of the arc across the electrode that invariably occurs in these lamps does not result in a positive flicker but is "just enough to give a sort of sparkle or animation to the light."

The natural colour of the light is white, and these lamps are commonly used in diffusing glass globes to give a soft effect. In certain regions, however, such as the famous "Path of Gold" in San Francisco, a yellowish tone is obtained by the use of suitable tinted panes of glass. Clear globes are, however, also used, and the fact of the light coming from a bridge of vapour of considerable length is also regarded as an element contributing to softness of light. Another point emphasised is that the light is derived from a vertical column of vapour, and is therefore a maximum in a horizontal direction. Relatively little modification of the natural distribution of light is therefore necessary in order to secure conditions favourable to street lighting.

White-Way Illumination.

A feature of street lighting in American cities has been the method known as "white-way illumination," the latest development of which, described as "super white-way lighting" was adopted in San Francisco in October 1916. Generally speaking, white-way lighting involves the use of clusters of high-powered incandescent or luminous arc lamps, commonly installed in diffusing white globes in ornamental standards. In the latest form, such lighting utilises standards 18 ft. or more in height, carrying two, three or more high-power luminous arc or incandescent fixtures. The distinction from the old white-way methods is mainly a matter of higher posts and more powerful units, coupled with greater illumination. The cost of installation is stated to be four to eight dollars per foot frontage, as compared with one to two dollars per foot on the original white-way basis. For such lighting, gas-filled lamps of 1 000, 1 500 and 2 500 c.p. are commonly used. In the original article some effective photographs of streets lighted by these methods are shown

Another matter to which much attention has been given is the design of ornamental street-standards of which attractive illustrations are also given. For general work 600 to 1 000 c.p. lamps are installed in diffusing globes about 17 in. in diameter and 18 to 20 in. long. This is assumed to give a degree of brightness that can be viewed without disagreeable sensations of glare. Apart from the shaping of the standards, colour is of some importance, and it is considered preferable for them to be painted in some light tint of buff, green, or brown. Even trolley-poles, also carrying lights, have been subjected to decorative treatment.

The Finance of Street Lighting.

A point of considerable interest in connection with street-lighting is the method of finance. It is stated that three chief methods are employed.

1. Popular subscription amongst business men or property owners, or both.
2. Installation by the lighting company, which charges a slightly higher rate for current to amortise the original investment.
3. Financing by commercial clubs or other civic organisations which, in turn, pro-rate the cost against members of the organisation.

This special white-way lighting, the nearest equivalent to which is perhaps what is known as "parade-lighting" in this country, is regarded as being of special benefit to business houses fronting on the region so illuminated. In some states the "Improvement Law" has been modified to enable a special assessment to be levied against the abutting property on which the improvement is made. Statistics are presented showing the comparative expenditure on lighting of a large number of cities. It is perhaps difficult to draw general conclusions from such statistics. It appears, however, that the expenditure on lighting varies from 1·23 to 3·86 per cent. in different cities—in any case a comparatively small proportion. The average cost per capita for 227 cities with populations over 30 000 has been found to be approximately 72 cents. There are, however, a few cities whose expenditure rises over 3 dollars per capita. For the 50 best lighted cities the average per capita is about 2 dollars. The yearly cost of street-lighting commonly varies from about 2 cents per linear foot of street for a poorly lighted village to over 5 dollars for an intensive system such as that in Market Street, San Francisco. The average for all streets in the United States, excluding "white-ways," would not exceed 5 cents per foot per year. However if, as is indicated by the acceptance of extra lighting in many districts, property owners and merchants consider it a good investment to pay over 6 dollars to light one foot of street, the question may be raised whether it is not worth while for a city to consider paying at least 5 cents ?

Classes of Street Lighting.

Setting aside special white-way or spectacular lighting, Dr. L. Bell divides street lighting into three classes, *i.e.*, (1) those in which to the ordinary requirements of safety and convenience something is added with a view to display; (2) normal street-lighting suitable for thoroughfares carrying important traffic; and (3) lighting for residential and other streets where traffic is small and requirements of the police are not severe. For the highest grade of lighting the eye must receive enough light to get beyond the "twilight vision" stage, and, in practice, the most important public streets should receive an average of 0·25 foot-candle. In such cases one may compare the street to a corridor, the sides of which receive fairly liberal illumination in order to produce an agreeable effect. Powerful arcs, placed fairly high and spaced at a distance not over four to five times their height are effective.

The great bulk of street-lighting, however, demands less exacting conditions, and a general order of illuminating comparable with full moonlight, and ranging say from 1·20 down to 1·50 foot-candle should answer. Here the larger incandescent lamps of 100 to 500 W prove useful.

Need for Careful Tests.

In view of the low orders of illumination practicable in most street-lighting, illumination tests, if embodied in the contract, require special care. A sufficient number of lamps must be tested, and due consideration must be given to the effect of reflection from buildings, shadows cast by trees and other extraneous factors. Important decisions should be based on laboratory tests, where exact conditions can be noted. The most logical method, in rating lamps for street-lighting, is to specify the mean spherical candle-power, and to describe the lamp by type. Allowance for depreciation of incandescent lamps during life must also be considered. With regard to failures of lamps it is suggested that the central station should be given sufficient notice to replace a defective lamp before the deductions are made. If not replaced within twenty-four hours the central station may be deemed liable to a penalty.

The choice of the type of glass for the diffusing globes now becoming commonly used for street-lighting presents interesting problems. The aim of modern design is to secure complete diffusion of light without undue loss of light, and without the globe becoming too heavy. Diagrams show that increasing weight is accompanied by progressive increase in absorption of light, but a transmission of 87 per cent. is claimed for some of the latest "alabaster" and "carrara" glassware. Generally speaking the transmission varies from 60 to 80 per cent. according to type. Considerable improvements in the manufacture of such diffusing glass have been made during recent years. Various special units intended to modify the natural curve of light distribution so as to secure even illumination in streets have been devised. Some of these depend on the use of prismatic glass refractors.

One special type, the "Highway" lighting unit, consists essentially of two approximately parabolic reflectors pointing down the street in either direction, whereby the peculiar curve necessary for theoretical even illumination of pavement may be secured.

There appears to be much activity in the development of HYDRO-ELECTRIC POWER IN THE UNITED STATES at present. The Southern Power Company has let a contract for a 80 000 H.P. hydro-electric plant at Mountain Islands for $3 000 000, and it is also to develop 60 000 H.P. at Great Falls (S.C.). Contracts, amounting to nearly $3 500 000, have been placed by the Southern California Edison Company for generating plant and auxiliary apparatus for a 75 000 kW plant, an additional hydro-electric unit at an existing station, sub-station equipment, and the conversion of the 150 000 V Big Creek lines to 220 000 V operation.

Recent Progress in High Frequency Inductive Heating.*

By E. F. NORTHRUP.

A somewhat detailed description is given of the furnaces designed by the author for heating with high frequency currents. The furnaces are made by the Ajax Electrothermic Corporation. The high-frequency converter sets used for the purpose have been greatly simplified. Those under 25 kW are designed for operation on single phase circuits. They include three essential parts, namely, an oil-cooled transformer, with internal reactance, a set of condensers, and a metal discharge gap. A diagram of connections for a 20 kW set is shown in Fig. 1.

Where the supply voltage is 6 600 V, it is practicable to operate the three-phase high frequency converter set directly off the supply circuits, no step-up transformers being required. On the other hand, three high-tension reactances of 25 kVA capacity must be inserted in the supply line to limit the flow of current. An oil-switch must be used as a starting switch; and two current and two potential

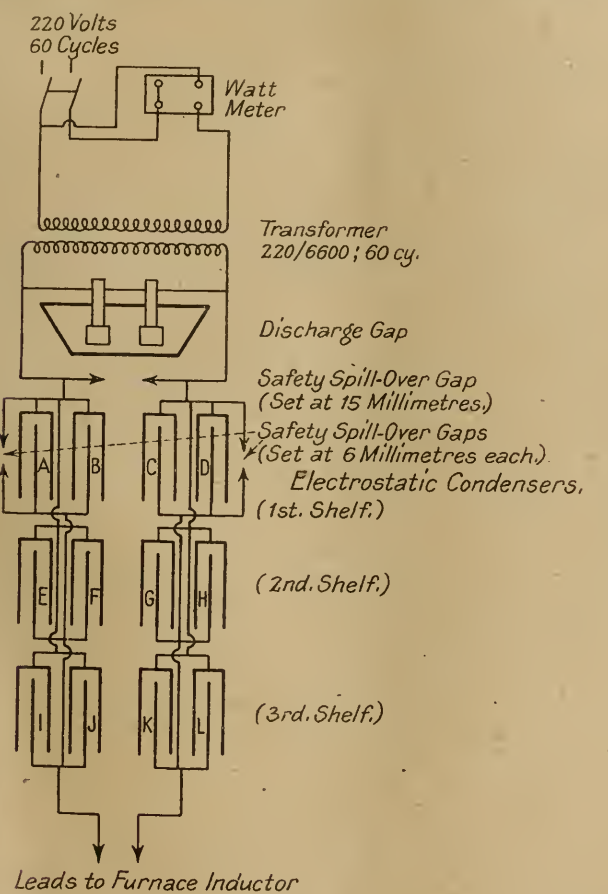

Fig. 1.—Theoretical Diagram of Connections of 20 kW High Frequency Converter Set.

transformers are needed to operate the integrating wattmeter. There is, therefore, a loss in simplicity and little is gained in economy of first cost in operating directly from high-tension supply lines.

Facts About High Frequency Converter Sets.

On account of the intrinsic high cost of transformers and condensers, these high-frequency converter sets constitute from 80 to 90 per cent. of the selling price of a complete metal melting outfit. The high-frequency converter sets have, however, no moving parts and the nature of the materials which enter into their construction is such that they depreciate scarcely at all.

These high-frequency converter sets have proved in practice to be so reliable and efficient, as constructed in units not exceeding 60 kW, that a high-frequency alternator of this rating could scarcely compete with them in simplicity, ease of operation, life and cost. It is only when single units of over 100 kW capacity are considered that we should look to the high-frequency alternator of about 12 000 cycles per second as the better apparatus for supplying high-frequency current for heating purposes. Satisfactory alternators of 200 kW capacity have been designed, but as yet they have not become available.

Types of Furnaces.

Several types of furnace are described in the original paper. A high temperature furnace, which may be used with a vacuum, is shown in Fig. 2. Here the inductor coil is made of 42 turns of in. (1 cm.) flattened copper tubing. The inductor is wound as a solenoid

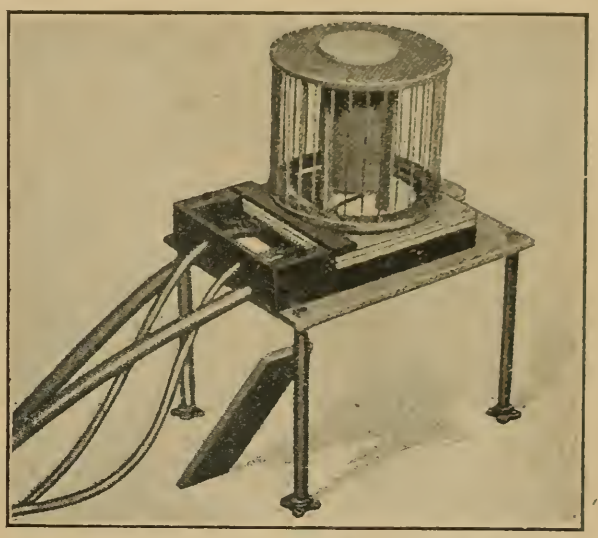

Fig. 2.—Standard D—1 Model Furnace.

and is 9 in. (23 cm.) long and $4\frac{3}{16}$ in. (10·5 cm.) inside diameter. The high frequency potential is applied to the terminals of this solenoid and also a water pressure of 30 lb. (13·7 kg.) or more, which maintains a flow of water through the flattened tubular solenoid. The furnace may be used as a vacuum or as a non-vacuum furnace. It is of the non-tilting type, and its contents are removed through the bottom by withdrawing a slide of asbestos board. This type of furnace under favourable conditions will melt molybdenum and can

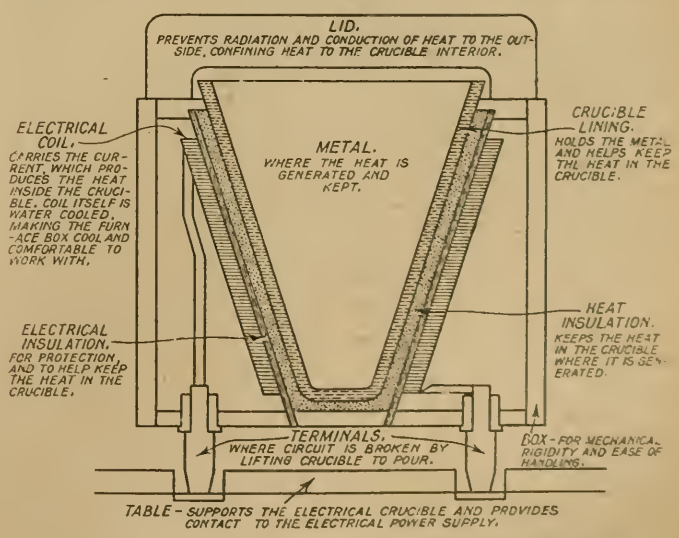

Fig. 3.—Cross Section of Ten-Inch "Electric Crucible."

be used to melt electrolytic iron in 5 to 6 lb. (2·3 to 2·7 kg.) lots strictly carbon free. The furnace is very suitable for the recovery of platinum scrap. When a crucible of carbon or Acheson graphite 2¼ in. (5·6 cm.) inside diameter by 7 in. (17·5 cm.) long is used, and this is heat-insulated with lampblack, it is not difficult to obtain temperatures in from fifteen to twenty minutes which are more than sufficient to graphitise carbon completely.

Electric Crucible Furnaces.

For melting in vacuum, a quartz tube is used closed at the bottom, which just fits the coil. Electric crucible furnaces are made in the form shown in Fig. 3. Since all types of furnaces operated by high-

* Abstract of a Paper read before the American Electrochemical Society.

frequency induction are substantially at room temperature on the outside, they can be handled very easily. A furnace of this type is well adapted to the melting of precious metals and will melt and pour about 15 lb. of copper. The melting is extremely rapid, and when non-conducting crucibles are used the molten metal becomes violently stirred, so that there is perfect mixing.

When very high temperatures are required in electric crucibles, it has been found advantageous to maintain a flow of water through the inductor coil, the water connections being made by means of rubber tubing.

Several high-frequency furnaces have been used in the United States Mint in Philadelphia. With an in-put of 121 kW per phase 5.905 lb. of silver were melted per kW hour, but, in this case the furnace was really underloaded.

In the case of metals which do not take up carbon it is advantageous to employ graphite crucibles, but these are subject to the disadvantage that they oxidise and burn away. To overcome this difficulty the author has developed a coating which will not oxidize at a temperature of 1 800° C., even when a jet of oxygen is steadily blown upon it. The coating is put on at a temperature of 2 200° C. An additional coating of zirkite, magnesite, &c., may be easily applied.

In the original paper some particulars are given on the use of special furnaces for heat treatment and graphitisation, c. With regard to the latter, lamp black, or carbon black, is found to be the best of all insulators at temperatures above 2 000° C.; it is also an electric insulator when not strongly compressed. Consequently, when a pile of carbon blocks are embedded in this material and inductively heated with high frequency current, they are heated rapidly and uniformly and can be quickly brought to the temperature of graphitisation. The efficiency compares very favourably with that of other methods.

Magnetic Properties of Compressed Powdered Iron.*

By B. SPEED and G. W. ELMEN.

The development of a successful method of compressing insulated grains of iron to produce a material magnetically and electrically suited for use in the telephone plant has had a determining effect upon methods of loading and compositing telephone lines and the introduction of carrier current systems of multiplex telephony. This material is used in the construction of the cores of the loading coils introduced to increase the inductance of a telephone circuit, also in the cores of inductance elements in filters for carrier current systems, and reactance coils and transformers for radio telephone circuits. Such coils have to meet special requirements.

The inductance, and hence the permeability, of the loading coils must remain constant throughout the entire range of intensities (as much as 1 : 100) of the currents employed.

In addition, the variation in effective resistance caused by hysteresis, which occurs when two currents of different frequencies and amplitudes are superposed, must be so small that "flutter" in the transmitted speech is inappreciable. Finally, the total resistance of the coil, including copper loss, must be small compared with the resistance of a length of line conductor equal to the length of the loading section. Hence the effect of hysteresis and eddy currents which depends upon the frequency and amplitude of the telephone currents must be reduced to a minimum.

Meeting the Requirements.

These requirements were met successfully in the early development of loading coils by the use of hard iron either in wire or in sheet form. Cores of hard-drawn wire were developed and adopted by the engineers of the American Telephone Telegraph Company, and were used successfully until the core-material herein described was put on a production basis. Two advantages pertain to the use of hard material in preference to soft. In the hard material the variation in permeability for a large range of magnetizing forces is less than in the soft iron. This is especially true at the initial part of the magnetization curve where, for a very large range of magnetizing force, the permeability of the hard material is constant. The second advantage is due to the fact that over the range in which the permeability is constant the hysteresis loss per unit of volume is less in the hard than it is in the soft material for the same flux density.

Design of the Coils.

In order to take advantage of the constancy in permeability and the low hysteresis loss with small magnetizing forces, the coils were designed so that for the range of speech currents the magnetizing force corresponded to that of the initial part of the magnetization curve. In a standard design of coil the magnetizing force corresponding to an average telephone current of one milliampere is of the order of 0·01 gauss.

In addition to the magnetic requirements for the core-material, its electrical resistivity is also of great importance.

Originally cores of hard-drawn wire were used. Hard material is preferable to soft as the variation in permeability is less, especially at the beginning of the magnetization curve: also the hysteresis loss in these circumstances is smaller. In a standard coil the magnetizing force with one milliampere is about 0·01 gauss. Electric resistivity is also important. The frequency of speech currents is about 800 per sec., and with low resistivity eddy current losses are excessive. Hence iron wire of 0·004 in. diameter was used, separate convolutions being insulated.

The Need for Stability and Constancy.

With the introduction of repeaters requirements as regards stability and constancy became more stringent, and air gaps were introduced at right angles to the path of the flux. For various reasons the symmetrical placing of such gaps is important. The making of such fine hard drawn wires required diamond dies, the importation of which was greatly hindered by the war. Fortunately, powdered iron cores were developed to a commercial stage. The requirements of such materials are (1) a permeability at low magnetizing forces between 20 and 100, (2) material finely divided at right angles to the flux to decrease eddy currents, (3) low hysteresis loss, and (4) favourable cost of manufacture. Finely divided iron, in some cases consisting of particles treated with wax, was often proposed, and the use of particles of iron oxide was studied. In general, however, little was known of compressed material.

The iron powder used first in these investigations was mixed with a little water and heated at 100 to 150° C. until the particles had a layer of oxide on them. Finally, it was mixed with a thin solution of shellac, dried and pressed into rings under a pressure of 100 000 lb. per sq. in. Thus the desired order of permeability, between 50 and 60, was obtained. Other methods of insulation were tried, but were less satisfactory. Ultimately it was found that if iron powder was rolled in a zinc-lined drum for a few hours and then insulated with shellac solution, very tough insulation, which did not break down under compression, was obtained, coupled with a higher specific resistance. This method was eventually adopted in preparing powdered iron cores. A suitable quality of hard iron was obtained by electrolysis from a solution containing ferrous sulphate and chloride and ammonium sulphate. The deposited iron was stripped off the steel electrodes and ground fine, until 30 to 50 per cent. would pass through a 200-mesh sieve. An annealing process was also used and had an appreciable purifying effect. At the present time three grades of material, having respectively permeabilities of 50, 35, and 25 are made. Tensile strengths of the three varieties are 1 375, 925 and 375 lb. per sq. in. sp. gravity 7·1, 6·4, and 6·0. A diagram relating specific resistance to pressure for annealed and unannealed material is also given in the original Paper. At 120 000 lb. per sq. in. values of 0·007 and 0·003 for annealed and unannealed material. At 260 000 lb. per sq. in. a sp. resistance of the order of 0.001 Ohm-cm is recorded. In the original paper full data on remanence, coercive force, &c., are also appended, and magnetization curves are given. The greatest changes in specific gravity occur below 100 000 lb. per sq. in.; additional pressure while altering specific gravity but little, may double the maximum permeability. With a sp. gravity of 7·4 the specific resistance of the compressed uninsulated powder is 30 to 60 times that of solid iron. The effect of air spaces in the insulated and uninsulated varieties is notably different. The maximum permeability recorded for compressed iron is 545—as high a value as can be obtained from many grades of solid iron.

The following data are of interest:—

Kind of Material.	Permeability. Maximum.	Permeability. H = 0.
Electrolytic iron, wrought bar	7 800	250
Poor grade of cast steel, annealed ..	710	131·5
Poor grade of cast steel, hardened ..	170	58
Cast iron, annealed	620	175
Cast iron, unannealed	240	69·4
Iron powder, annealed, uninsulated, compressed with 254 000 pounds pressure	540	80
Iron powder, unannealed, uninsulated, compressed with 254 000 pounds pressure	156	52
Grade A iron-powder cores	156·5	54·8
„ B „ „ „	57·2	30·2
„ C „ „ „	48	26·3

In the final section of the article an account is given of the plant used in the preparation and compression of these powdered iron cores.

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Reviews.

Die Transformatoren. By M. Vidmar. (Berlin: Julius Springer.) Pp. xvi.+702. Price 120 marks (bound).

This is an excellent book. It is also a remarkable book. The author is a professor in the University of Ljubljana, and director of the Ljubljana Engineering Works and Foundries. It interested us to discover where Ljubljana was, and after numerous enquiries we were assured that it was none other than the town known as Laibach in the old, ramshackle empire commonly called the Dual Monarchy. Thus the book emanates from a Jugo-Slav University, about 50 miles north of Fiume. Though written in German and published by a famous Berlin house, there are many phrases which one would scarcely expect in a book written by a "Reichsdeutscher," e.g., "Der Witz des Grosstransformators."

Interest is aroused in the preface, which is an essay to show the proper place of the engineer in the world. Here we have to do with an idealist, who makes no attempt to conceal his subjective standpoint. We shall now try to indicate a few of the interesting points dealt with in a treatise of 700 pages.

Generally speaking, the author's method of treatment is to start from first principles and leave off when he has exhausted the subject as far as he is able to do so. In the chapter on the magnetic circuit, among the matters dealt with are the current rush on switching in and the third harmonic of the magnetising current. When dealing with windings, additional losses with various arrangements of copper, the disruptive forces on short-circuit, pressure surges, switching phenomena and capacity are among the matters discussed. In a chapter of about 100 pages on heating, a great deal is said about radiation, conduction, convection, time-constant, intermittent working, overloads, &c. The relations between cost and efficiency and between cost and main dimensions are discussed by every writer on transformers, and the present author is no exception. The next three chapters deal with air-cooled transformers, oil-cooled transformers, and water-cooled transformers.

The problem of the large transformer appears to have a special charm for the author, and after paying his devotion to Bláthy, one of the pioneers in this work, he describes in detail the design of his largest transformer.

The following particulars of this construction of Ganz of Budapest may be of interest: Normal output 16 000 kVA, with a continuous overload capacity of 30 per cent., by increasing the cooling water from 200 to 300 litres per minute. Frequency 50 cycles per second. Pressure-ratio, 4 000/56 000 V. Total weight, 35 tons. Efficiency at normal load and unity power-factor, 98.65 per cent. The no-load current is 7 per cent. and the short-circuit pressure 5.6 per cent. In addition to this 3-phase, core-type transformer, the author works out a single-phase, shell-type, furnace transformer for 3 000 kVA and 500/60 000 A, also built by Ganz.

Enough has been said, however, to give the reader a fair idea of the contents of the book. Though objections can be taken to various arguments, we have not found anything to make the book unworthy of the serious consideration of all who are deeply interested in transformers. There is no doubt that the book will be a standard treatise for years to come. It is printed and illustrated in the excellent manner common to Springer's publications, but intending purchasers are advised to buy *bound* copies.

Stanley Parker Smith.

The Elements of Direct Current Electrical Engineering. By H. F. Trewman, M.A., and G. E. Condliffe, B.Sc. (London: Sir Isaac Pitman & Sons, Ltd.) Pp. vii.+219, 7s. 6d. net.

The authors suggest in their preface that there was a gap existing between elementary text-books on magnetism and electricity and the more advanced books which deal with the design point of view, and their aim was to bridge this gap. We can hardly subscribe to the view that the gap was as great as is suggested, for there are many text-books, bearing the too frequently used label of "Electrical Engineering," which connect the pure with the applied science. However, the authors have prepared a concise course designed for second-year university students, and presumably especially designed for their own students at the Ordnance College, Woolwich. The course assumes that the reader has an elementary knowledge of the Calculus, and no attempt has been made to avoid its use. The book is written in twelve chapters, the first four dealing with the fundamentals of electro-magnetism and induced current, after which there are chapters on instruments, storage batteries, the dynamo, the magnetic circuit, commutation and armature reaction, losses, operation of dynamos, the motor, and motor testing. Numerous examples are provided and answers are supplied. The authors ask for suggestions and the notification of errors. On page 169 it is stated that if a series dynamo be charging a battery, and the battery E.M.F. becomes greater than the dynamo E.M.F., "the current will be reversed in both armature and field, and therefore the machine will run as a motor in the same direction"! This error is not repeated in the motor chapter.

The compound wound dynamo is treated very briefly, and we would suggest a note on the paralleling and load-sharing, as this would help to indicate the reasons for the more general use of one type of winding. The word "expotential" on page 25 is an obvious misprint.

Finally, we suggest that the method of deducing the strength of the magnetic field due to a current is based on an unjustifiable assumption, namely, that the magnetic force produced by a current is automatically the same as the electric force produced by a charge.

J. Paley Yorke.

The Diagnosing of Troubles in Electrical Machines. By Prof. Miles Walker, M.A., D.Sc. (London: Longmans, Green & Co.) Pp. xi.+450. 32s. net.

During the last few years, quite a number of books have been written, especially in America, on diseases of machines and their remedies, but none that we have reviewed can approach Prof. Walker's book for real solid interest and value.

A reader has not to read far into the first chapter on "breakdown of insulation" before realising that the author is drawing on a vast experience; and then the fearful thought flashes through the mind whether any one firm could possibly survive if it encountered but a fraction of these multitudinous mishaps. Nor is the reader consoled by the author's assurance that "the accidents that can happen and the mistakes that can be made are so diverse and numerous, and the ways in which a defect in the machine can hide itself are so perplexing, that one can only hope to deal with a small percentage of the troubles and to indicate the general methods of attacking problems of the kind."

Another thought that flashes across the mind on reading of the strange things that have happened or may happen to electrical machines is the following. Granted that many of these failures belong to the troublous period of birth and infancy of many types, one still wonders whether many of these breakdowns or troubles ought to occur at all. Candidly, we think not. We have no sympathy with the American idea of rapid "antiquation." Engineers have no right to waste Nature's resources in this way—rather, they should build thoroughly reliable machines, which will only break down in case of untoward accident. Everlasting "cutting" can be carried too far, and the possibility of exact calculation ought not to be strained too much—briefly, in this respect, electrical ought not to be worse off than other machines.

The first few chapters on breakdown of insulation, over-heating, low efficiency, &c., contain a great deal of well-digested information arranged in an orderly manner. Here, of course, many standard well-known methods are included; but let not the reader think he is going to be let off with a mere list of possible faults and remedies. Dr. Walker's method is a very different one—he is concerned that the reader shall understand the cause of the trouble, and spares no pain in analysing the underlying theory. Much of the material will be found as useful for designers as for testers—indeed, the technical information is given so as to be serviceable to all.

A particularly pleasing feature about the book is the clear and fair way in which methods or arguments taken from various publications are given: the author makes the digest of the subject so thorough as to render reference superfluous. Another instance

of the wide aspect on which the book is based is evidenced by the care taken to show how vector diagrams should be used to attack problems in connection with windings and the like.

After the more general sources of failure have been dealt with, the failures which occur in the several types are treated in separate chapters. Among the more important sections may be mentioned those devoted to balancing, in which a simple theory of this important subject is included; defects in core construction; unbalanced loads; synchronising troubles, with a theory of phase swinging; symmetry of armature windings; instability of continuous-current generators; a lengthy and very valuable investigation into commutator and brush troubles, with a complete discussion of remedies; starting and other problems in rotary converters and induction motors.

The notes we made when reading the book include the discovery of very few corrections and omissions. When dealing with equalising currents in lap-connected armatures, reference might perhaps have been made to the work of Lulofs and Hawkins; while in the useful expression for finding the temperature by resistance, it would probably be better to give this for the final temperature, leaving the rise to be found by deducting the temperature of the surrounding air.

No more need be said in praise of this excellent book. There is no doubt that it will soon be as popular as its sister book on design, to which it is similar in every respect. We only wish that more authors would compel their publishers to produce artistic technical books, with good binding, large text and well-drawn diagrams, and also bind them so that they will remain open when opened, as is the case with Prof. Walker's books. The book can be strongly recommended to all who are interested in the technical side of electrical machinery. S. Parker Smith.

Switching Equipment for Power Control. Stephen Q. Hayes. (London: Hill Publishing Company.) Pp. vii. + 463. 20s.

To one familiar with Mr. Hayes' career this book is very disappointing. Of all switchgear engineers he has travelled most extensively, but he writes solely of American practice and material. During twenty-five years' connection with switchgear industry Mr. Hayes has built up an international reputation which justifies the expectation of much greater things than are exhibited in this book. The whole tone of the book suggests the salesman, and there is usually little difficulty in identifying the "manufacturers . . . descriptive matter utilised bodily," which the author acknowledges in his preface. In the reviewer's opinion there is far too much of this matter, much of which appears to have been included so as to avoid giving offence to firms competing with the author's employers.

The space is not well allocated. Five pages on instrument switches, nine pages on fuses, two and a half pages on automatic protection, twenty-six and a half pages, mostly catalogue quality, on switchboard meters, and only forty-eight pages on cubicle work and layouts.

Editorial work is conspicuous by its absence. Sentences and even whole paragraphs are duplicated (see §§2 and 5, p. 96; §5, p. 106 and the last lines of p. 107; § 1, p. 364 and § 1, p. 407). Related matter is separated. Thus one page and an illustration is given to portable sub-stations in the chapter on large panel switchboards, and another two and a half pages on the same subject appear later under circuit breaker structures. A table should have replaced a long, involved sentence, full of figures, on p. 94. The article before a noun is frequently omitted, and phrases such as " . . . currents of 600 to 1 000 at 650 V . . . " omitting the "amperes," are common.

The only notes regarding the use of reactances appear in the chapter on lightning arresters, and practically nothing is said about their application to the switching system. More attention should have been given to system connections as a whole. The diagrams of elements are often excellent, but the uninitiated are left seeking the proper method to combine these elements.

The contrast between British and American practice is emphasised by the statement that it is *customary* to omit automatic devices on a.c. generators, although *recently* a scheme of differential protection has been adopted. The latter system is given six lines, and split-conductor protection a like amount.

The sixteen pages on automatic sub-stations are of considerable interest, and among other matters of note to British engineers may be mentioned the automatic reclosing circuit breaker, the graphic recording synchroscope, which show the exact phase relationship at the instant of paralleling, the glow synchroscope for high voltages and the multiple Kelvin balance totalising graphic meter.

On the whole, the book is likely to be useful to those who want to know *what* American manufacturers are doing, without bothering about the *why*. In a future edition the author will do well to prune ruthlessly the manufacturers data pages, and to elaborate on such items as the operation of voltage regulators, means of insulation for high voltages, the application of protective relays, the action of lightning arresters, and the general substitution of definite information for vague statements.

The printing, binding and production generally is well up to McGraw-Hill standard, the only possible criticism being that a few of the blocks are too small for convenient reference.

W. A. Coates.

Wireless Telegraphy and Telephony: An Outline for Electrical Engineers and Others. By L. B. Turner, M.A., M.I.E.E. (Cambridge: University Press.) Pp. x. + 195. Price 20s. net.

The object of the present volume is to provide an introduction to wireless telegraphy and telephony which will serve as a groundwork for electrical engineers and others who already have a knowledge of electrical work, yet are unacquainted with radio developments. The book is chiefly theoretical for the first three chapters. The difference between wireless and other branches of electrical engineering is pointed out, the author always bearing in mind the object of his book. Radiation, oscillatory circuits, and methods of coupling receive attention in the second and third chapters. The fourth brings us to methods of producing high-frequency alternating currents. Spark methods are treated in an elementary manner which will be readily understood by the electrical engineer for whom special analogies are repeatedly given. Alternators and arcs are then explained. The explanation of the arc's action is such that it will leave many of the readers of this book still in the dark unless the circle is to be narrower than we imagine.

The author's comments on arc signalling are open to dispute. As Mr. Shaughnessy has recently pointed out, the double-wave method of signalling is likely to cause less interference at high speeds—the speeds of the future—than the single wave. A steady aerial load on the continuous-wave generator has many advantages in high-speed working. The author's opinion, however, of arc signalling is a high one, and he considers it to be the best available at present for high powers.

Chap. V. brings the reader to methods of detection. Simple receiving circuits are described in connection with crystal detectors. Chap. VI. brings us to the all-important thermionic vacuum tube. The author's treatment of vacuum tubes is exceedingly good. The development of the subject is lucid and logical, and, while there is no room for numerous practical examples, yet typical circuits are described and explained.

The author's remarks on p. 97 regarding the constancy of the grid current curve need some modification. He asserts that the anode potential has practically no effect on the grid currents. The following figures obtained from a similar valve will speak for themselves. When the potential difference across the filament was 4 V and the grid potential + 20 V, the grid currents obtained were: With 12 V on the anode, 3·6 milliamps; 34 V, 1·25 milliamps; 50 V, 0·75 milliamp; 90 V, 0·5 milliamp. The author's grid current curve of Fig. 61, which he says remains the same practically for anode voltages of 10 to 139, represents the grid current for grid potentials from 0-50 V. The greater the grid potential the greater the error of such an assertion.

In connection with the author's remarks on p. 141, it has been found that breaking the grid circuit is not suitable for high-power transmission. Fig. 111 omits a microphone battery. Fig. 118 shows the anode battery connected the wrong way round.

After dealing with the subject of triodes and their applications, the author gives some information regarding direction finding and the trend of modern development. He trusts, as we all do, that there will be some improvement in atmospheric eliminators. The reviewer feels that we are lacking in inventive ability if we cannot get over this trouble, and are taking the easier but probably far more expensive alternative of increasing the power of the transmitting stations. The problem can be solved if we get down to it.

Mr. Turner is to be congratulated on the production of this valuable little book. Even at its excessive price it is still not merely of great interest to the student, but also to those of wide experience who are yet anxious to see problems from a new and original viewpoint.

John Scott-Taggart.

The London County Council has made a two years' agreement with the London Electric Supply Corporation for the supply of electrical energy to the new County Hall, from July 1, 1922, on the following terms: (*a*) Lighting, 5⅜d. a unit for first 1 000 units a year for each kW of plant installed (for first year the plant to be calculated on a basis of 750 kW), and any consumption beyond at 3½d. a unit; (*b*) Power, 2⅛d. a unit for all power and heating required from July 1, 1922, to June 30, 1923. After that date the price to be increased or decreased by 0·002d. a unit for every penny a ton by which the cost to the company during the year ending December 31, 1924, of standard fuel having a calorific value of 11 000 B.th.u. rises or falls above or below the average cost to the company of such standard fuel during the year 1923; (*c*) "Stand-by" supply for lighting, 5d. a unit, the Council bearing cost (39s. 6d. a yard) of laying the cable over Westminster Bridge to provide this supply.

Protection of Electrical Apparatus.

Thermally Actuated Relays.

The load capacity of any piece of electrical apparatus is determined by the temperature limits of the materials used in the construction of the device. This characteristic sets a definite maximum load which can be applied continuously.

In many cases, this load can be considerably exceeded for short periods of time without danger to the apparatus. In other cases, a succession of short-time heavy overloads can be applied without injury, if followed by intervals of very light load, for the heat developed is integrated over a considerable period of time, and the temperature attained as a result of successive short overloads is the same temperature as would be obtained if the integrated loading had been applied continuously for that same length of time.

Induction Motor Conditions.

The squirrel cage induction motor is a typical example. Such a motor takes a rather heavy starting current, especially if it is of small size and is thrown directly on the line without starting compensators. Fuse protection is generally supplied, but in order to take care of the starting current the fuse capacity must be several times normal full-load running current. This condition results in the possibility of the motor being overloaded to a considerable extent without blowing the fuses, and, if the overload continues long enough, the motor may burn out. The fuses then only provide protection against an overload sufficiently great to stall the motor.

This condition should be protected against, and the thermal relays recently developed by the Westinghouse Electric & Manufacturing Company are applicable for this purpose.

The theory of protection demands that an instrument be provided which can be connected in electrical circuits, the instrument to have in itself small losses which are converted into heat, and the device should be so arranged that its temperature rises in proportion to the current flowing through the circuit, and also designed to embody a considerable heat capacity. The temperature in the relay will then follow approximately the temperature of the apparatus to be protected, and the relay can be adjusted so that it will open the circuit when a predetermined temperature is reached.

The relay may be arranged with or without a pointer to indicate its own temperature continuously, and, therefore, the temperature conditions of the protected apparatus, thus giving an idea of the amount of load which has been placed on the apparatus and the increase in load which may be safely applied.

In designing the thermal relay it was necessary to obtain a heat sensitive material which would have sufficient power to operate a

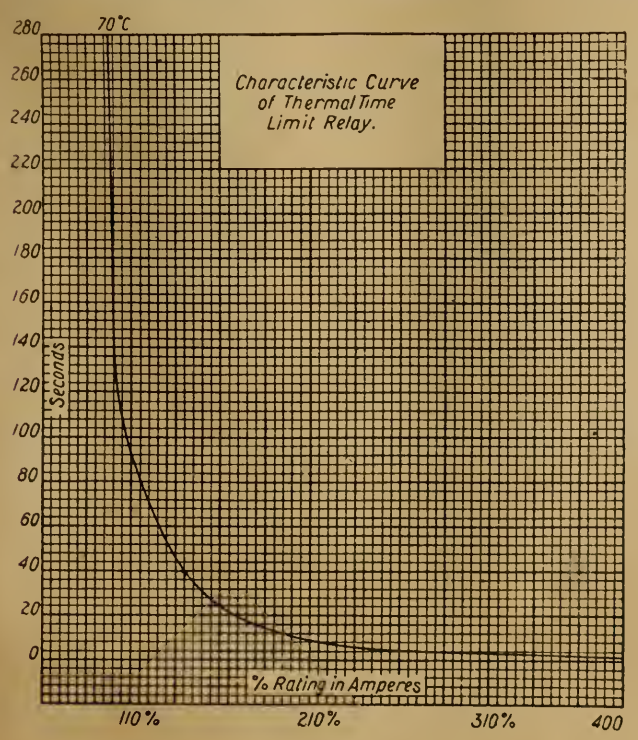

Fig. 1

contact and still accurately follow changes in temperature. A high grade of thermostatic metal was found satisfactory for this purpose. In order to obtain the greatest simplicity of design, this same material is used as the resistor or heat developing element, as well as the heat sensitive element.

Operating Mechanism.

The operating mechanism of relay consists of a number of sheets of thermostatic metal arranged in series or in parallel, and with varying resistance, according to the desired current-carrying capacity. A contact is attached to one of the elements, and is normally held with an initial tension against the stationary contact. At the proper temperature the bending tendency of the thermostatic metal takes up this initial tension and the contacts open, thus opening the holding coil of a small circuit breaker to open the main circuit.

Fig. 1 shows a characteristic relay curve. At room temperature the relay may be arranged to carry continuously in the neighbour-

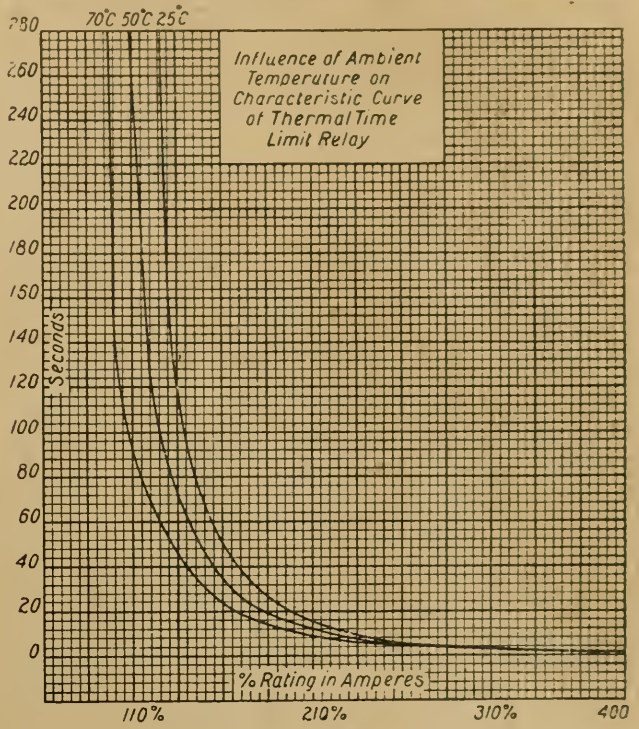

Fig. 2.

hood of 110 per cent. of its rated capacity. If the current exceeds this value, the relay will operate with a time element, as shown by the curve. Fig. 2 indicates the effect of change of external temperature, the various curves being marked to show the temperature at which the determinations were made. It will be noted that the change in external temperature only changes the capacity of the relay by a small value. The amount of this change depends on the operating temperature of the relay, the higher the operating temperature, the less influence.

This change, however, is in the proper direction to give protection to apparatus operating in conditions of elevated temperature. If the relay carries less than its rated current for a time, or after operating has not fully cooled to room temperature, and an overload occurs, the contacts will open in less time than indicated by the curve in Fig. 1, but since the cause of this condition has also elevated the temperature of the protected apparatus, the added measure of protection is in the right direction.

Metric System for Engineers.*

This book gives a full and practical explanation of the metric system of measurement in so far as it is met with in engineering calculation and measurements. It is intended to be of use to draughtsmen, mechanics and others who have to deal with calculation and measurement on the metric system, and we may say at once that it is clearly and carefully written and distinctly justifies its place in the series of "directly useful" books.

In dealing with length and area and volume measurement, attention is given to the measuring devices in use—micrometers and planimeters, for example—and calculations in connection with screw-cutting and gear wheels are treated at some length. Mass and weight, force, velocity and acceleration are treated, followed by the derived units of measurement, such as torque, work and power. The C.G.S. system of absolute units and the practical derivatives are carefully explained, and throughout the book worked examples are provided in plenty.

There are thirty-four excellent tables of equivalents, which sum up the deductions arrived at in the various chapters, and some conversion charts which may hang up in the office are supplied in the wallet at the back of the book.

Though the author surveys briefly the various arguments for and against the compulsory adoption of the metric system, he does so very honestly and does not use his book as a pulpit for propaganda work.

There are twenty-eight illustrations, and the general get-up of the book is excellent. J. P. Y.

*Metric System for Engineers. By C. R. Clapham, B.Sc. (London: Chapman & Hall.) Pp. xii. + 181. 12s. 6d. net.

Industry in Spain in 1921.

In his report on the INDUSTRIES AND COMMERCE OF SPAIN for the year to December, 1921, Capt. V. de B. Charles, Commercial Secretary to H.M. Embassy, Madrid, states that the year under review could hardly be described as encouraging to British exportere. High costs of production, high freights, and a high exchange rate too often proved an excessive handicap against the low production costs, low freights, and low rate of exchange of Germany, France, and Belgium. With a further obstacle to overcome in the form of an increased tariff, Great Britain had been engaged in an uphill struggle against heavy odds. Under these difficult conditions a welcome enterprise had been shown on the part of individual manufacturers by their efforts to meet the Spanish buyer halfway. This new spirit of flexibility was appreciated by the Spaniard, and would undoubtedly bear fruit when conditions improved. At equal prices British goods were still preferred owing to their reputation for quality. In fact, within reason they often found a market even at higher prices.

Imports.

An advance has been made in the import of British textile machinery, though Germany and France both gained a considerably larger share of the total trade than they had last year. Great Britain also supplied the greater part of the multi-tubular cylindrical steam generators, though here again the preponderance of British imports was not so pronounced as it was a year ago, Belgium and Germany having secured an increased share. In semi-fixed steam and gas engines Great Britain captured substantial orders from the United States of America, but was overtaken and left far behind by Germany. In fixed machines under 10 tons Great Britain just retained the lead. Cranes, another preponderantly British import, were bought in increasing quantities from France and the United states. In pumps Great Britain fell back from the first place to the third, behind the United States of America and Germany. Agricultural machinery also showed a marked falling off. This is an important market, which, it is suggested, it would well repay British manufacturers to study. Germany again prevented Great Britain from securing the lead in dynamos, motors and switchboards between 401 and 2 500 kgs. in weight, for which the demand was doubled. The British figures, nevertheless, showed an appreciable improvement. In telegraph and telephone apparatus British manufacturers gained more trade, which the United States of America lost, though Germany was more successful still. In cables, both electric and haulage, the same thing happened—Great Britain and Germany both sold increased quantities at the expense of the United States. In machine tools the loss to the United States and gain to Germany was repeated, but in this instance Great Britain also failed to maintain last year's trade. Motor-cars were practically a dead trade since the increase in the duties in November, 1920.

Transport.

The railway problem in Spain to-day is stated to be similar to that in other countries. Operating costs long ago reached the point where freight and passenger rates must be increased, or some other form of relief discovered if the companies are to continue to run without a heavy loss. Public opinion is against any increase in rates, and if this attitude is maintained it is said that State subvention or nationalisation would seem to be the only solution.

Under the new Cabinet a scheme for the reorganisation of the railways was introduced in October last, and a special committee was appointed to consider the question, but nothing has yet been settled. The central Catalan extension is being rapidly completed, and considerable progress has been made since last year. It is proposed to operate this line electrically on account of the heavy gradients.

The absorption of the Madrid Tramway Company by a Spanish Company has naturally resulted in demands for all tramway material being placed where possible with Spanish manufacturers, but owing to the enormous increase of cost the company were unable to supplement the entirely inadequate service unless they obtained permission from the Municipality to raise the rates on certain routes. This permission has been granted, the increased rates to take effect on each line as soon as extra cars can be put on that line. Where workmen's services are concerned, however, very small increases, if any, have been adopted. Further concessions extending the various services to outlying districts have been applied for, but owing to the shortage of material and electric power it is doubtful whether these will materialise for some time to come. In other towns in Spain and the Balearic Isles considerable extensions of tram services are reported, notably a line from Granada to La Zubia, which will put the villages to the south-west of the Sierra Nevada within easy reach of Granada. There should be openings, it is stated, for British material, especially motors, when prices come down and if more moderate customs duties are arrived at.

Hydro-Electric Works.

During the year under review hydro-electric development was principally confined to installations of small horse-power, although construction proceeded on a number of important installations in different parts of the country. The new power station erected by the Ebro Company at Camarassa, to the north-west of Barcelona, where the plant, which is one of the largest—if not the largest—in Spain is now in operation, giving 150 000 H.P. to the industry of Cataluña. The Hidroeléctrica Española, the second most important company in Spain, have nearly completed construction on their station at Dos Aguas, the junction of the rivers Jucar and Gabriel, to the south-west of Valencia. This station will give some 100 000 H.P. when completed, and will help to improve the inadequate power and light service of Madrid, where the demands have increased so enormously in the past few years that the existing stations are quite insufficient to meet the requirements. The problem in Madrid is very acute, and it appears within the bounds of possibility that a large steam power station will have to be erected to make Madrid independent of power stoppages due to an inadequate rainfall. The enormous potential horse-power of the Ebro and Duero rivers are still unharnessed, although it is said that the international difficulties have nearly been overcome and development is now not likely to be long delayed.

Luminous Signals for Power Stations.

The illustration below shows the latest luminous signal apparatus manufactured by SIEMENS BROTHERS & COMPANY. The increasing size of central power stations and the extensions to smaller stations which have been necessitated by the greater consumption of electricity for light and power, have rendered necessary the provision of means for enabling engineers in charge of switchboard attendants to signal orders to engine drivers both rapidly and efficiently. The Siemens luminous signalling apparatus fulfils this purpose, as it enables such orders to be transmitted with certainty. The apparatus acts in a positive and reliable manner by causing luminous signals to appear and, at the same time, calling attention by an aural signal.

The complete equipment comprises a transmitting apparatus, a receiving apparatus, and a Klaxon horn or other electric calling device. The transmitter—which can be supplied either in a pattern designed for attachment to a wall or suitably mounted on a column, as in the illustration—is enclosed in a cast-iron case having eight circular

TRANSMITTING AND RECEIVING APPARATUS.

windows, on which the orders sent appear by illumination. As shown in the illustration, the transmitter is actuated by means of a movable handle. The receiver consists of a sheet-iron case with a glass front, upon which the orders received also appear by illumination. A push button switch is provided at the side to enable the engine driver to acknowledge the signal. If desired, this switch can be installed at any convenient position apart from the receiver. An order sent by actuating the transmitter handle is immediately illuminated on the transmitter as well as the receiver, and the call will sound at the receiving end.

The luminous signal will remain visible both on the transmitter and on the receiver, and the aural signal will continue until the engine driver acknowledges the signal by operating the press button switch. As soon as this button is pressed the lamps are extinguished and the circuit to the aural signal is broken. This obliteration of the signal at the transmitting, as well as the receiving, end serves as an indication to the sender that the signal has been received.

The whole apparatus is of simple design, and is very strong, all parts being substantially constructed and of simple size.

AN ELECTRO-MAGNETIC SAFETY CATCH for railway carriage doors has been invented by Messrs. A. Crankshaw and T. Markland, of Wigan, who have obtained protection rights. By this device immediately the guard of a train closes the door of his van every carriage door on the train is automatically locked, and cannot be opened until the guard's door is unfastened. This patent can also be used by householders in conjunction with a bell-push.

Italy in 1921.

The same uphill struggle to bring INDUSTRIAL CONDITIONS in Italy back to the normal is reported by H.M. Commercial Secretary at Rome (Mr. J. H. Henderson) in his annual review on the commercial, industrial, and economic situation, as by the Commercial Secretaries of other countries. The Budget deficiency, the adverse balance of trade, taxation and labour disputes were among the chief factors which had to be dealt with. Though not rosy, the outlook for 1922 is said to be brighter.

British Trade with Italy.

The aspect of the Italian market at the end of 1921, from the point of view of British trade, was stated to be distinctly unfavourable. One merchant put it that "most British business for many months past has consisted in collecting old debts, or trying to collect them, with as little sacrifice as possible, rather than resort to lengthy law suits." Another estimated that the stock which he used to sell in one year would now, at the present rate of demand, take over five years to dispose of. With some exceptions, of which the most notable are textile machinery, tinplate machinery, machinery accessories such as belting, and English cloth, there was practically no demand for most of the British products which previously had a sale in the country. In the case of coal, England's principal export to Italy, there was recently a slight revival.

In some cases this state of trade is attributed to the high prices asked for British goods, prices which, it is stated, would limit the demand even if there were no question of exchange. The failure of British exporters to study the conditions of the market is also given as one of the reasons why British trade is not more flourishing. In the opinion, however, of local observers, by far the most important factor is that of exchange. It is becoming common to agree in the contract on a maximum rate of exchange, giving the buyer the faculty of paying either at this rate or at such lower market rate as may be current when payment is due. To the extent to which the conditions of business permit, this method is strongly recommended to the attention of British exporters, since it is a very popular one with the Italian buyer and is a strong inducement to him to do business.

Foreign Competition.

England's principal competitors at present in the Italian market are Germany and America, and of these the former is by far the more formidable on account of the advantage she possesses in depreciated currency. During the first half of 1921 the volume of trade between Italy and Germany was practically the same as between Italy and France. Germany thus took the third place along with France among the countries with whom Italy trades, as compared with sixth place in the corresponding period of the previous year. Moreover, the volume of German trade was three-quarters that of Great Britain, as compared with one quarter in 1920.

Railway Electrification.

The position of railway electrification at the end of last year is summarised as follows :—

1. *Lines which are working at present, in all about* 650 *kilometres.*—Turin-Trofarello-Chieri (completed in 1921); Turin-Pinerolo-Torrepelice and Brichevasio-Barge (completed in 1921); Turin-Susa (completed at the end of 1920); Turin-Modane and Bussoleno-Susa; Genoa-Busalla-Ronco; Genoa-Mignanego-Ronco; Genoa-Savona-Geva; Milan-Varese-Porto Ceresio; Monza-Calolzio-Soncino-Colico.

2. *Lines which are now being electrified.*—Ronco-Alessandria-Asti-Trofarello, to be finished in 1922; Novi-Tortona-Voghera; Ronco-Arguata-Tortona—(direct line)—Alessandria-Tortona; Genoa-Spezia-Pisa-Leghorn; Firenze-Pistoia-Bologna; Firenze-Faenza-Bologna.

Good progress was made during the year on these lines, and lately especially so on the Bologna-Pistoia-Florence and the Bologna-Faenza-Florence lines, and also as regards the construction of the material required for electrification generally.

3. *Lines which will be electrified in the near future.*—(*a*) Directed by the administration of the State railways :—(Direct line) Rome-Naples; Parma-Spezia-Fornovo-Borgo S. Donnio; S. Stefano-Sarzana; Piacenza-Voghera; Stradella-Bressana; Genoa-Ovada-Alessandria; Voghera-Milan-Chiasso; Uasmate-Bergamo-Bugamo-Ponte S. Pictio-Colobio; Bologna-Verona-Trento-Brennero; Triante-Opcina-Postuma; Trieste-Monfalcone-Gorizia. (*b*) By private enterprise :—Milan-Piacenza-Mestre-Venice; Mestre-Portoguaro-Monfalcone; Viareggio-Lucca-Pistoia; Pisa-Lucca-Castelnuovo-Garafagnana; Pisa-Empoli-Florence

4. *Experimental lines.*—Rome-Tivoli; Rome-Anzio-Nettuno; Benevento-Fozzile; Cagliasi-Monte Poni-Oristano.

When all these lines have been completed, the following lines, which are included in the general programme, will be electrified :—Turin-Milan-Verona-Vicenza-Padua; Savona-Ventimiglia; Florence-Chiusi-Rome; Orte-Foligno-Ancona; Faenza-Ancona-Castellammare Adriatico; Tivoli-Salmona-Castellammare Adriatico; Naples-Battipaglia-Paola-Reggio Calabria; Paola-Coscenza; Salerno Macato-S. Severino-Benevento; Torre Annunziata-Castellammare di Italia-Gragnano.

Hydro-Electric Power Stations.

The progress made during 1920-21 on the hydro-electric power stations for use in connection with these lines was as follows :—The Melezet was completed. The work on the Bardonecchia station, which uses the water power of the Rochesmolles, was brought to an advanced stage. A start was made on the central station of Saviana and Costrolo on the Reno and Linrentra near Bagni della Poretta, and also on the station on the Sagittario near Anversa Scanno.

Water Power.

In 1915 there were 329 establishments of over 300 H.P., which developed a total force of 935 000 H.P. In 1920 there were 383 similar establishments developing 1 152 120 H.P., and 54 (359 210 H.P.) were under construction. There were also 300 establishments of under 300 H.P., representing a total force of 300 000 H.P. In addition to these there are several large schemes in hand which will not be completed for some time. These include the artificial lakes in the valleys of the Reno and the Imentra, in the Bologna district, which will be used in connection with the electrification of the trans-Appenine railway between Emilia and Tuscany; similar work in the Abruzzi; the Silani lakes in Calabria, and the Tirso lakes in Sardinia. These schemes are calculated to produce 700 000 H.P. The artificial lake at Tirso, it is stated, will have a capacity of 416 million cubic metres, and will be the largest in Europe and the third largest in the world.

New Electricity Companies.

The principal companies founded during the first half of 1921 included E. Breda (Milan), with a capital of 60 000 000 lire; Euganea di Elettricita di Venezia, and Elettricita del Veneto Centrale (Padua), each with a capital of 10 000 000 lire.

Telegraphs.

Almost every commune with a population of over a thousand has a telegraphic service. The Government are proposing to lay cables connecting Rome with Messina, Catania, and Syracuse, and also between Ravenna and Trieste, and between Genoa and Nice, which it is hoped will be completed by the summer. In 1918-19 Italy possessed 3 981 kilometres of cable, in 1920-21 4 904 kilometres, and in 1921-22 there will be more than 6 000 kilometres. Telegraphic communication between Italy and abroad is in the hands of foreign companies. This is considered to be a danger to Italian political and economic independence. It is expected that this will in part be remedied by the laying of Italian national cables to South America and to Greece. Powers to undertake this work were conferred on the Government by a decree dated Aug. 20, and the schemes are under active consideration. For the construction of the South American cable a company is being formed with a capital of from 75 to 80 million lire gold, subscribed principally by Italian residents in Brazil, Argentine, Uruguay, Chili, and Peru. The cable will be 13 000 kilometres long, and it is hoped that it will be completed in three years.

Wireless.

Italy possesses a regular wireless service with her colonies and with ships, and in 1920-21 three million words were transmitted or received. It is the intention of the Government to develop and extend this service to foreign countries.

Telephones.

The question of telephones is stated to be urgent on account of the insufficiency of the service. The total number of town subscribers is 120 000; public call offices, 3 000; trunk lines, 40 000 km.; and trunk calls less than 10 000 000 a year, almost all of which are accounted for by the public authorities and the Press. The unsatisfactory condition of the Italian telephone service is the subject of constant complaint. It used to be attributed to the incapacity of the private companies, but to-day two-thirds of the telephones are operated by the State, and still more than half of the communes in Italy are without telephonic communications.

The Government have been authorised to expend 150 million lire on telegraphs and telephones, the expenditure to be spread over four years. The immediate programme as regards telephones is :—(1) The completion of the automatic exchanges in the principal towns; (2) the laying of new lines to carry the increased traffic; (3) the connection of 409 important towns with the trunk lines; (4) the re-establishment of direct telephone communication with the principal cities in Central Europe; (5) the improvement of audibility between the extremities of Italy; (6) the completion of the laying of trunk line cables between Milan, Genoa and Turin; (7) the erection of wireless stations.

The expenditure on the telephone service in 1920-21, without making allowance for depreciation and interest on capital, was 74 million lire, against a return of 68 million.

Presentation to Mr. J. D. Morgan.

At the annual meeting of the South Midland Centre of the Institution of Electrical Engineers, Mr. R. A. Chattock (chairman of the Centre) presented to the hon. secretary, Mr. J. D. MORGAN, on behalf of the members, a silver coffee pot and milk jug of the Georgian period, as a mark of their appreciation of his services, and of the esteem in which they held him as a fellow-member of the Centre. Mr. Chattock stated that Mr. Morgan took up his duties as hon. secretary just over ten years ago. During his period of office the membership of the Centre had increased from 450 to 795. In addition, a sub-centre at Loughborough had been formed, and also the Local Student's Section, which was proving very valuable to the younger members of the profession. Mr. Morgan was now devoting himself to some very special scientific research work, and it was on this account (and so that he might devote himself wholeheartedly to it) that he found it necessary to relinquish the honorary position which he had held for so long.

Parliamentary Intelligence.

Grampians Electricity Bill.

The Select Committee of the House of Commons which has been considering this Bill passed the preamble, with certain reservations, on the 4th inst., and the clauses were settled on Tuesday.

Engineering Details.

Mr. Basil Mott, consulting engineer, said that Loch Ericht was so situated in relation to other lochs and streams of the scheme that it could be utilised as a good reservoir for impounding water. The River Tay had not only the largest drainage area in Scotland, but its head waters were so placed as to render its development for hydro-electric power eminently suitable. The water could be used five or six times over at the various falls. Altogether 417 square miles were laid under contribution by the whole scheme. Loch Ericht could be reservoired without inundating any land of much agricultural value. By damming each end of Loch Ericht the storage capacity of the loch would be 80 000 000 000 gallons. When completed the Loch Garry reservoir would have a storage capacity of 410 000 000 and Loch Rannoch 1 600 000 000 cubic feet. The latter would be useful as an adjunct, because it would enable the storage of flood water which came down in wet seasons. In time of spate the double power-house below Rannoch would be used, and that at Ericht would be closed down.

Mr. J. Hall Rider, consulting engineer, said that by supplying 118 000 000 units of electricity he estimated they would save 160 000 tons of coal per annum on the first part of the scheme, while on the whole scheme they would save 436 000 tons per annum. The overhead transmission system would be about 165 miles, but in the first stage it was not proposed to go further than 10 or 15 miles south of Perth. In the first instance, it was only proposed to reach Perth and Dundee. The total expenditure for the first section would be £2 603 000, and for the whole scheme £4 500 000. On the completion of the first stage, if they assumed a sale of 170 000 000 units per annum, the cost per unit would be 0·3 996d.; but the price charged to the consumers would be higher, because of other charges to be taken into account. At Dundee the cost of production in May, 1920 (exclusive of capital charges), was 1·14d. per unit, and at Perth the working costs were 1·83d. per unit in 1921. Excluding Edinburgh and Glasgow, which were special cases, the cost of production under the Grampian scheme would be lower than any of the existing steam stations after capital costs were included.

Sir Henry Babington Smith said that Mr. Pease, deputy chairman of Lloyd's Bank, and the Duke of Atholl were to be added to the list of first shareholders, the latter being desirous of being associated with a movement that would develop the Highlands. The Credits Facilities Committee would be prepared to recommend a guarantee on debentures, provided the scheme satisfied the Electricity Commissioners and the Bill was passed by Parliament. The guarantee would be of considerable advantage, but they would have to raise their £1 000 000 capital before they could get the guarantee.

In reply to the Chairman, Sir H. Babington Smith said negotiations were in progress with financial houses, and, in his opinion, the Ericht scheme, which was the larger one, would be the best to carry out first.

Mr. Alex. Newlands, chief engineer to the Highland Railway Company, said he had no authority from his directors to speak as to their intentions with regard to electrification, but he had gone into the question from the point of view of figures only. For the railway from Perth to Inverness (118 miles) the estimated demand, calculated upon summer traffic for 1920, would be 4 500 h.p. on an average, the peak demand being 13 000 h.p. He was unable to say whether it would be economical or not to electrify the railway without full details of the present costs. Apart from the question of costs, electrification would enable the company to run heavier trains and at a higher rate of speed. The Highland system was largely single lines, and at the moment the maximum carrying capacity had been reached. If more business was to be dealt with the question of doubling part of the line at least would have to be considered.

Committee's Findings.

Major Ormsby Gore said that in view of the fact that all opposition had been withdrawn, the Committee were willing to pass the preamble, provided certain alterations were made in Clauses 8 and 9 of the Bill. They could not depart from the usual practice that statutory companies in which the capital was limited by statute should be enabled to get further capital without recourse to Parliament, and they thought that the capital should be provided collectively by share capital and borrowing powers to meet the estimated cost of the first stage of the scheme. The Committee were impressed by the evidence that the two power stations on the Ericht and the Tummel were to be the main sources of power and that they should be proceeded with as a whole. The scheme was more likely to be a success, and to attract customers if the whole of that first stage was definitely authorised and proceeded with. The cost of that first stage was given as £2 600 000. The Committee felt, therefore, that the authorised share capital, together with the borrowing powers, should meet that amount at least. If it had not been for the letter of the Trade Facilities Act Advisory Committee, the Committee could not have seen their way to authorise the issue of debenture stock to an amount exceeding one-half of the ordinary share capital. The Committee were prepared to accept, in view of all the circumstances, a suggested amendment to Clause 9, with the additional proviso that the company should not be able to raise by debentures or mortgages, even with the consent of the Electricity Commissioners, an amount more than the equivalent of the ordinary paid-up capital. That was to say, the Committee gave the company powers to borrow without the consent of the Electricity Commissioners half the amount of the ordinary share capital, and a further half with the consent of the Electricity Commissioners.

The Bill was reported to the House on Tuesday.

Post Office Estimates.

In explaining the Post Office estimates in the House of Commons on Thursday last, Mr. F. G. Kellaway, Postmaster-General, said that in 1920-21 the deficit on the Post Office commercial account was £7 300 000, but in 1922-23 he estimated on present charges a surplus of £9 300 000. But for last year's increases in postal charges the deficit, instead of being £1 800 000, would have been £5 000 000. The improved position was entirely due to the drastic reductions of expenditure, amounting to £10 650 000. Last year the staff was 191 000; to-day it stood at 185 000

The collection of letters on Sundays would be restored on May 28, but he did not propose to reinstitute the delivery of letters on Sunday. The charge for inland letters not weighing more than 1 oz would be reduced from 2d. to 1½d., the rate for letters over 1 oz. remaining as at present. On letters to the United States and all parts of the Empire the rate would be reduced from 2d. to 1½d. for those not over 1 oz., but for those over 1 oz. the present charge would remain. These concessions would cost £3 800 000 and £150 000 respectively for a full year. The postcard rate would be reduced from 1½d. to 1d., costing £600 000. The printed paper rate would go down from 1d. to ½d., costing £1 640 000, but he stipulated that printed papers, unless posted by 3.30 p.m. in London, would not be entitled to be dealt with that day.

Telephone Tariff Changes.

During the past year the number of telephone stations had increased by 16 691, and on March 31 was 995 242. The total number of new subscribers was 75 500, and the number of cessations was 64 000, of which 29 000 were due to the increased tariff. During the year 530 rural call offices had been opened at post offices, and 3 290 had been opened on rural party lines. In submitting proposals for the reduction of charges, he did not propose to proceed on the principle recommended by the Select Committee of an all-round percentage reduction. He would make a reduction of telephone rental to private users of £1 10s. a year, making the rental in London £7, in Birmingham, Liverpool, Glasgow and Manchester £6 10s., and in the rest of the country £6. The cost of the concession would be £200 000 in a full year and £160 000 this year. There would be a reduction of the local message fee from 1½d. to 1¼d., which would cost £440 000 in a year and £350 000 this year. He estimated there would be an increase of 5 per cent. in the number of calls. He also proposed to lower the extra mileage charge on private wires and at terminals from £10 to £8, at a cost of £120 000 this year. The principal proposal in regard to trunk calls was that there should be a substantially cheaper rate for calls between 2 p.m. and 7 p.m. The average reduction of the rate would be 25 per cent. He proposed to abolish the local fee on all trunk calls over 1s. 6d. in amount, and to make modifications below that charge. The present charges for telephone facilities in country districts were undoubtedly almost prohibitive, and amounted in many cases to a rental exceeding £20. That was due to the heavy capital cost in connection with most rural extensions. He proposed that where not less than eight subscribers could be got, the installation rental should be £8 per subscriber, and the local and trunk fees according to the ordinary tariff. The cost of a night service, if required, could be met by additional charges. He did not propose in future to require any guarantee for a junction line unless the capital cost exceeded £1 000. Where fifteen or more subscribers were obtained, the service would be provided at £7 10s. for business houses or £6 for residential lines within a mile radius. He was unable to adopt the recommendation of the Select Committee on Telephones that the telegraphs and telephones should be united, as it would be extremely expensive.

Wireless "Broadcasting."

Referring to the question of the broadcasting of wireless messages, or radio-telephone broadcasting, Mr. Kellaway said that the system had a great vogue in the United States, where there had also been a considerable increase in the number of transmitting stations, and the result of that increase had been chaos. He hoped we should be able to learn from the experience of the United States, and that we would have a reasonable service without causing interference either with the commercial use or the Government use of the wireless or with the facilities open to each other. He would allow a limited number of radio-telephone broadcasting stations. The country would be divided, roughly, into areas centring upon London, Cardiff, Plymouth, Birmingham, Manchester, Newcastle, Glasgow or Edinburgh (but not both), and Aberdeen, and one or more broadcasting stations would be allowed in each of those areas. Permission for those stations would only be granted to British firms who were *bona-fide* manufacturers of wireless apparatus. It was impossible for him to grant all the applications for the right of transmission, but he would ask the various firms who had applied to come together at the Post Office and co-operate, so that an efficient service might be rendered, that there might be no danger of monopoly, and that each service should not be interfering with the efficient working of the other. The stations would be limited to a power of 1½ kW, and furnished with wave lengths which should not interfere with other services. The normal hours for broadcasting would be

from 5 p.m. to 11 p.m., except on Sundays, when there would be no limit. There would be certain regulations in regard to the character and class of news which these agencies could transmit.

West Indies (Cables).

In reply to Mr. GIDEON MURRAY (House of Commons, May 4), who asked the Secretary of State for the Colonies what progress had been made in connection with making provision for an efficient telegraph service from Great Britain to, and between, the various British West Indian Colonies upon the termination of the present agreement with the West Indian and Panama Telegraph Company, Mr. WOOD said that negotiations were still in progress for the construction of a new cable from Bermuda to Barbados and beyond, but he was not in a position to make any statement on the subject at present.

Great Eastern Railway (Elcctrification).

Replying to Mr. MALONE in the House of Commons last week, Mr. NEAL said he was aware of the congestion on certain routes of the Great Eastern Railway, and he had been in consultation with the company and had informed them that the Trade Facilities Committee were prepared to consider an application from them for assistance in raising capital for electrification work, but he understood that they did not propose to make such an application.

Coal Mines (Safcty Appliances).

In reply to Mr. CHARLES EDWARDS (House of Commons, May 1), Mr. BRIDGEMAN stated that it was impossible for the Government to test the numerous patent safety appliances, as the only real test of the efficiency of such appliances lay in experience of their behaviour over an extended period under actual working conditions.

Dartford Light Railways Order.

The Minister of Transport has confirmed the DARTFORD LIGHT RAILWAYS (AMENDMENT) ORDER, 1922, authorising additional borrowing powers for the purposes of the light railways authorised by the Orders of 1902 and 1903, and has issued an Order authorising the construction of light railways in the borough of Plymouth.

Legal Intelligence.

Tramway Arbitration Appeal.

Last week a Divisional Court (Lush and Greer, JJ.) heard a motion by West Bromwich Corporation to set aside an award by Sir Lynden Macassey in an arbitration between the South Staffordshire Tramways (Lessee) Company and the Corporation.

Mr. DISTURNAL, K.C. (for the Corporation) said that the arbitrator had made a series of declarations after his award, and it was contended he had no jurisdiction to do so. The matter arose out of a lease granted by the Corporation to the company of the tramways within their area. The Corporation undertook to keep in repair the tramways and the roads between the tracks and 2 ft. on either side of the rails. There was a covenant under which the lessees (the company) agreed to contribute to the net cost, plus a percentage for overhead charges, of the renewals. They undertook to pay that sum annually to the Corporation for the net cost of the track renewals as distinguished from the track and the adjoining pieces of the road. There were agreements entered into from time to time varying that stipulation in the lease. Ultimately there was an agreement in 1917 under which the Corporation were to keep the tramway in the condition it had been during the war and the company should contribute £1 500. The arbitration arose in connection with the question, whether or not the Corporation had perfomed their obligation in keeping the tramways in repair in accordance with the agreement.

The company sent in particulars of damage they said they had sustained, but the arbitrator found that they were not entitled to any of the damage claimed, and gave them 40s. nominal damages for what he held were breaches of covenant as against the Corporation, and the 40s. had been tendered to the company in the course of the proceedings. The arbitrator then made a series of declarations for which one could not see the necessity. He made a declaration that the Corporation had broken their covenants, and he found the damages were represented by £2, and he also made a declaration in respect of all matters which another arbitrator must take into consideration in considering what further sums the company should pay by way of contribution to the Corporation in respect of repairs to the line. In the document which varied the lease there were certain fixed periods and an arbitration clause under which an arbitrator could be appointed, in default of agreement to say, notwithstanding the terms of the lease, what should be paid as the annual contribution to the Corporation for repairs, but he had made a declaration which would bind any other arbitrator.

Mr. TYLDESLEY JONES, K.C., having argued in favour of the award,

Mr. JUSTICE LUSH said the only question was whether on the pleadings the parties consented to enlarge the dispute, but he did not think they did. It would be better to remit the matter to the arbitrator to expunge from the award so much of it as related to declarations of the future. He was not surprised that the arbitrator was in doubt as to what issues were raised on the pleadings or what disputes were referred to him.

Mr. JUSTICE GREER agreed, and the award was accordingly remitted.

The "Telur" Stop Clock.

The "Telur" stop clock for controlling the length of telephone conversations on trunk calls has recently been produced by JAMES MCMILLAN & COMPANY. The dial is divided into twelve minutes. The clock is started by pressing the handle to the left, and a bell rings at three-minute intervals, or any other period which may be

THE "TELUR" STOP CLOCK.

specially required. It is stopped by pressing the handle to the right, and it can be restarted from this position by pulling out the handle from the right-hand position. To start the clock from zero the handle is pressed over to the left.

The illustration shows the clock as supplied for giving alarm by bell, but the manufacturers also supply it fitted with terminals for lighting a signal lamp at the periods required.

Induction Motor for U.S. Super-Dreadnoughts

At the East Pittsburgh works of the WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY a number of motors are being built to propel electrically the super-dreadnoughts included in the Naval programme adopted by the Limitation of Armaments Conference. Four motors are required to propel one battleship, one motor being directly coupled to each of the four shafts.

The motors are each rated at 16 500 H.P., at 227 revs. per min., and are designed for the most economical operation at two ship speeds—the battle speed of 23 knots and the cruising speed of 15 knots. This result is obtained by the use of two entirely separate stator and rotor windings in the motor. At the battle speed, one set of windings is used, and, at the cruising speed, the other set is operative. Sixty thousand cubic feet of air per minute is required to conduct away the heat losses developed in operation. This amount of ventilation air for a period of fifty minutes is equal to the weight of the motor.

Marble Firm's New Premises.

In a few weeks' time PERCY C. WEBB, LTD., marble merchants, will move to their new premises at the Marble Wharf, Verney-road, Old Kent-road, on the Surrey Canal. The wharf covers an area of nearly an acre, with a frontage of about 80 ft. to the Surrey Canal. It has a substantial building, about 161 ft. long by 62 ft. wide. This was burnt down some few months ago, and is now being reinstated. The plant from the present premises, both at Dalston and the Docks, will be moved, and, further saws, polishing machines, and cranes installed. The welfare of the staff has not be overlooked: a large mess-room is to be provided for the workmen, while a rest-room and library is allocated for the use of the office staff. When all is completed, the firm will have one of the finest marble yards in London, if not in England.

The late Mr. SAMUEL RICHARDSON BLUNDSTONE, consulting engineer, for many years editor of the "Railway Engineer," lately chairman of the Wolverhampton District Electric Tramways, Ltd., and the Dudley, Stourbridge, and District Electric Traction Company, Ltd., a member of the council of the British Electrical Federation, Ltd., a director of the Birmingham District Power and Traction Company, Ltd., of the South Staffordshire Tramways Company, and the South Staffordshire Tramways (Lessee) Company, Ltd., who died on Feb. 12 last, has left estate of the gross value of £19 334, with net personalty £18 955.

Electricity Supply.

RAWTENSTALL Electricity Department made a surplus of nearly £2 000 last year.

A profit of £4 098 has been made by DARWEN Electricity Department during the past year. Last year the profit was £3 111.

The net profit of the ROCHDALE Electricity Department for the past year is £22 649. Of this £15 649 is being placed to reserve and £7 000 is set aside for the relief of the rates.

A public inquiry is to be held at the end of this month by the Electricity Commissioners into an application by the SOUTH-EASTERN AND CHATHAM RAILWAY COMPANIES to erect a generating station on the company's land known as Angerstein's Wharf, Charlton, Kent.

The British Insulated & Helsby Cable Company have applied to HUYTON-WITH-ROBY Urban Council for permission to : (1) change the declared pressure of supply at consumers' terminals from 100 V to 115 V, or, alternatively in special cases, to 230 V; (2) change their systesm of supply from single-phase at 100 frequency to single-phase at 50 frequency.

The feeder line from Hereford to Lydbrook, in the FOREST OF DEAN, has been completed, and the Hereford Electricity Committee are now supplying electricity in bulk to several industrial undertakings. It is anticipated that within the next twelve months the revenue from the Lydbrook line will be sufficient to justify the formation of a rural electricity scheme, by which the villages along the route will be able to be supplied with electricity.

The new generating sets which have been installed at the Montague-street SALVAGE DEPOT, BIRMINGHAM, in connection with the refuse destructor, were set in motion last week by the Lord Mayor (Ald. David Davis). The generating plant has been installed at a cost of £9 000, to utilise the steam raised by the burning of house refuse in the destructor which would otherwise go to waste. The current generated is sufficient to run the whole of the plant, for lighting the depot, and for charging the accumulators of the electrical vehicles used by the department.

New Schemes and Mains Extensions.

DONCASTER Town Council has applied for a loan of £32 522, for mains extensions, sub-stations, transformers, switchgear, services, and meters.

ORMSKIRK Council has appointed Mr. J. Scott to prepare an electricity scheme (in conjunction with the Liverpool Corporation) to submit to the Electricity Commissioners.

DOVER Town Council has applied for a loan of £600 for a superheater, and £1 200 for underfeed stokers, required at the Electricity Works, in order that Kent coal may be burnt exclusively.

SAFFRON WALDEN Town Council have appointed a committee to consider the expediency of establishing municipal electricity works. There are at present thirteen private plants in the town, and it is suggested that there would be a good general demand if the Council undertook the supply.

Electric Traction.

The accounts of DARWEN tramways for the past year show a loss of £201.

OLDHAM Corporation Tramways Department made a profit of £18 000 during the past financial year.

The accounts of RAWTENSTALL (Lancashire) Tramways Department for the past year show a surplus of over £4 000.

EDINBURGH Town Council have approved the draft of a Provisional Order to authorise certain tramway extensions, &c.

The accounts of ACCRINGTON (Lancashire) Tramways Department for the financial year just ended show a profit of £4 484.

The Ministry of Transport has rejected the application of the HULL Corporation for a Light Railway Order extending the tramways to Hessle, a scheme which was estimated to cost nearly £70 000.

The BURY (Lancashire) Corporation's tramway services have involved heavy losses during the past financial year. On the Bury service the deficit is £12 460, and on the Radcliffe section it is £2 856.

An expert report on the future of the CROYDON MUNICIPAL TRAMWAYS advises the leasing of the undertaking either to the L.C.C. or the South Metropolitan Electric Tramways Company, or both combined.

BURNLEY Town Council are applying for sanction to borrow £49 950, less £9 450 sinking fund contributions, for the relaying of tram tracks to the extent of over 9 000 yards on Padiham-road, Manchester, and Rosegrove routes.

WEST BROMWICH Town Council have decided to reconstruct the tram track from Carter's-green to the Birmingham boundary at a cost of £81 000, and to renew parts of the track from Carter's-green to Wednesbury and Tipton at £17 000.

THE LONDON ELECTRIC RAILWAY COMPANY AND THE CITY AND SOUTH LONDON RAILWAY COMPANY give notice of an application to Parliament for powers to raise additional capital by borrowing and creating second debenture stock, for extension of time for construction of works, and others matters.

Personal and Appointments.

LORD DERBY has accepted the presidency of the B.E.A.M.A. in succession to Lord Ampthill.

Mr. B. HUDSON, of Aldershot, has been appointed shift engineer at the Southport Electricity Works.

Prior to taking up his post as street lighting inspector under the Cardiff City Council, Mr. FRANK MARSH, for nine years foreman at Curran's Engineering & Foundry Company, Cardiff Docks, has been presented by the directors and employees with a gold watch.

Swindon Town Council has reduced, as from March 31 last, the salary of the electrical engineer, Mr. A. NICKLIN, from £500 to £425 a year, and that of the tramways manager, Mr. T. MEDCALF, from £520 to £494. Mr. Nicklin, who is suffering from a nervous breakdown, has been granted a month's leave of absence.

HACKNEY Establishment and General Purposes Committee recommend that the 10 per cent. addition for the increase in the cost of living included in the scale of salary payable to Mr. L. L. ROBINSON, borough electrical engineer, adopted by the Council on March 10, 1920, be discontinued, and that in future the salary of Mr. J. R. BOWDEN, deputy electrical engineer, be subject to a quarterly adjustment of 2 per cent. for each 15 points variation in the cost of living index figure as laid down in the schedule.

Mr. H. H. LANCASTER, Executive Officer of Blackpool Corporation Tramways, has been chosen out of fifty-eight applicants to succeed Mr. C. I. Baker as traffic manager. The position carries a salary of £400 with bonus, which must not make more than £500. Mr. Lancaster is a native of Blackpool, and entered the service of the Tramways Department in 1902. His father, the late Mr. James Lancaster, was at that time the general manager. After seven years Mr. Lancaster accepted the position of traffic assistant manager to the West Ham Corporation under Mr. H. E. Blain, where he acquired a wide experience of traffic arrangements. He returned to Blackpool to take up the position of executive officer in 1910.

Mr. HENRY JACKSON has resigned his position with the London & North Western Railway Company, having reached the age limit. Mr. Jackson was telegraph superintendent and electrical engineer to the Lancashire & Yorkshire Railway Company for 32½ years, and was transferred to the North Western Company when the amalgamation took place. He commenced his career with Tyer & Company in 1877, and in 1884 was appointed electrical engineer to the Furness Railway Company, and in these early days, in addition to railway telegraph work, had experience in electrical lighting of docks, petroleum storage, and ship lighting. In 1889 he was appointed to the position on the Lancashire & Yorkshire Railway which he has just resigned. He was chairman of the Railway Telegraph Superintendents' Conference in 1899, and again in 1915, for the duration of the War.

Catalogues, Price Lists, &c.

The L.F.A. (LONDON FACTORS & AGENTS, LTD.) have issued their May price-list of electrical accessories.

A new abridged net price-list (No. 95) of electrical accessories has just been issued by ELECTRICAL COMPONENTS, LTD.

ERSKINE, HEAP & COMPANY have just issued three new illustrated publications (pamphlets S.D. 1, A.T. 1, and R.S. 1), dealing respectively with their oil-immersed Star Delta, Auto-Transformer, and Rotor starters.

The "Stannos" concentric system of main distribution, which is being adopted in many of the housing schemes now in progress, and which is well known to readers of THE ELECTRICIAN, is the subject of Pamphlet 130 F recently issued by SIEMENS BROTHERS & COMPANY.

We have received from TROST BROTHERS a pamphlet describing the "Rotameter," an instrument for measuring and regulating the rate of flow of gases and liquids in distillation, absorption, reaction, mixing, &c.; measuring the consumption of air in compressed-air tools, of gas in stoves, engines, &c., petrol and fuel-oil consumption in internal-combustion engines; correct proportioning of gas mixture in oxy-acetylene welding, in mixed gas narcosis; as maximum demand meters, &c. For laboratory and research work instruments can be supplied to give accurate readings down to one hundredth of a cubic ft. per hour, and for industrial uses up to 100 000 cubic ft. per hour. The scale can be graduated to read in cubic ft., gallons, litres, lbs., &c., per hour or per minute. Pressures up to 120 lbs. per sq. in. and temperatures up to 220 deg. C. can be dealt with.

At Warrington last week, Mr. J. H. Brooking, general manager of the St. Helen's Cable & Rubber Company, was fined £5 and ordered to contribute two guineas towards the expenses of the R.S.P.C.A. on a charge of STARVING A CAPTIVE RAT. In order to test complaints that rats gnawed particular kinds of rubber insulation for cables, the rat had been caught and put in a cage, with three pieces of cable smeared with oil of linseed. It was given water once a day, and once a small piece of bread, which it ate ravenously. The animal lived under these conditions from Sunday to Thursday, when it died. Defendant advertised the result of the experiment, and the society were inundated with protests. Although a rat was only vermin, defendant became liable for ill-treating it in captivity. Mr. Steele, for the defence, admitted a technical offence in the interests of science.

Business Items, &c.

Mr. J. W. Russell, electrical engineer, of 49a, Fore-street, Hertford, and Watford, has opened a branch business at Ware.

The British Thomson-Houston Company have transferred their Swansea office to larger premises at Madza House, 7, Melbourne-place.

John Marsden & Sons, electrical engineers, of Huddersfield, have removed their business from Aspinall's-yard, Market-place, to 1, Upperhead-row.

The Hart Accumulator Company, Ltd., Stratford, London, has just opened a branch office at 6, Bridge-street, York, under the management of Mr. R. H. Rawlinson. A depot for the repair of storage batteries is also being prepared at the same address.

Mr. E. S. Spencer, of 80, Deodar-road, Putney, S.W. 15, informs us that he has resigned the managing directorship of the Aqua Electric Company, Ltd. He holds several inventions relating to water heaters, and would like to get into touch with any concerns interested.

Royce, Ltd., have just received an order from Kerr, Stuart & Company, of California Works, Stoke-on-Trent, for four Royce standard three-motor overhead electric travelling cranes, each of 40 tons capacity, and fitted with a 10-ton auxiliary lifting barrel, for export to India.

Mr. Richard Fitzhenry, formerly with the English Electric Company, Siemen's Works, Stafford, has been appointed commercial and technical representative for Callender's Cable & Construction Company, for cable joint boxes and junction boxes, and all cable accessories in the London district.

Johnson & Phillips, Ltd., of Charlton, London, S.E., whose Australian branch office is in Sydney, N.S.W., would be glad to hear from other British manufacturers desirous of Australian representation, whose products could be sold in conjunction with their own to mutual advantage. Their Australian manager is at present in London, and interviews could be arranged with interested applicants, by appointment.

We are informed that the Lassen Meter & Engineering Company, Ltd., has been acquired by James Gordon & Company, Ltd., of Windsor House, Kingsway, W.C. 2. Mr. J. J. Lassen has accepted the position of joint managing director, and will personally conduct the section of the business dealing with boiler efficiency appliances and instruments. The latter company also specialise in the design and manufacture of water power plant.

With a view to demonstrating the utility and consistent results produced with the Wilde-Barfield electric furnace, demonstrations will be held at the premises of J. H. Holmes, Portland-road, Newcastle-on-Tyne, for a week, starting on Monday next. Invitations are extended to anyone who may be interested, and visitors are asked to bring small samples for treatment. Further information can be obtained from either the Newcastle Electric Supply Company, or Prangnell Partners, 47, Pilgrim-street, Newcastle.

Mr. S. C. Hurry has been appointed sales engineer to the Jackson Electric Stove Company. Mr. Hurry joined the company on demobilisation in December, 1919, as assistant sales engineer. He has always been closely associated with electric heating and cooking developments. He started his training at the West Ham Corporation Electricity Department, before the favour "Sales Department" was instituted, and was afterwards at Torquay and Sheffield Electricity Departments, where he assisted in popularising domestic electricity

Institution Notes.

Mr. G. Thompson has been elected chairman and Mr. H. E. Dance vice-chairman of the Liverpool Students' Sub-Centre of the Institution of Electrical Engineers for the session 1922-23.

Under the auspices of the I.E.E., and in connection with the Dublin May Agricultural Show, Mr. R. Borlase Matthews is to repeat the paper, "Electro-Farming," which he read recently in London. This lecture will be given at 8 p.m., on the 16th inst., at Leinster House, Kildare-street, Dublin.

An invitation has been transmitted to the Iron and Steel Institute by Mr. L. Greiner from the Association of Engineers of Liége to participate in an International Congress which will be held at Liége in celebration of the seventy-fifth anniversary of the association, from June 11 to June 16. Members desiring to attend the Congress should communicate with Mr. O. Lepersonne, the general secretary of the Association of Engineers of Liége, 16, Quai des Etats-Unis, Liége. The latest date for the return of the forms is May 15.

The sixty-ninth anniversary festival dinner of the London Association of Foreman Engineers was held on Saturday at the Cannon-street Hotel, London, the chair being taken by Mr. F. W. Bellamy. The association has a membership of over 700 foremen, managers, and employers connected with the engineering industry, and its objects are purely educational and benevolent. The chairman, proposing "Success to the Association," referred to the aggressive tactics of the extremists in the engineering shops. No body of men, he said, had need of more tact to preserve the balance between the employers and men than the foremen. Some day they might have a less bitter dividing line between Capital and Labour. Mr. Austin Hopkinson, M.P., responding to the toast of "The Engineering Industry" (proposed by the Rev. J. A. S. Bullock), said that when the engineering trade was in trouble, as it was to-day, they as employers must consider whether there might be any fault with themselves, and should try and get a sympathetic view of what was going on in the minds of the workers.

At the annual meeting of the Iron and Steel Institute last week the new president, Mr. Francis Samuelson, announced the award of the Bessemer Medal for 1922 to Prof. Kotaro Honda, of the University of Sendai, Japan, who, he said, had established the theory of molecular magnetism based on the measurement of the change of volume in the steel when magnetised. The recipients of the Andrew Carnegie Research Scholarships for 1922 are: Mr. Arthur Bradley, who holds the D.Sc. (London) degree in Physical Chemistry, £100, to assist in studying the carburising and decarburising effect of different gases on iron and steel; Mr. Algernon L. Curtis, £100, to carry on researches in steel moulding sands and their behaviour under high temperatures; Mr. Owen W. Ellis, lecturer in metallography at the University of Toronto, £100, for studies in the effect of constitution on the malleability of iron and steel at high temperatures; Dr. J. Newton Friend, lecturer at the Birmingham Technical School, £100, to continue his corrosion tests on a large scale; Mr. Arthur M. Parkin, of Sheffield University, £100, for studies in the metallurgy of tungsten; Mr. Gosta Phragmen, of Stockholm, £100, to study the specific weight of molten metals by a new method; Mr. W. E. Williams, a graduate of the University of North Wales, £100, to study the application of X-ray spectography to the examination of the structure of steel.

Telegraph and Telephone Notes.

It is reported that the Soviet Government has approved the project of granting the Indo-European Cable Company a concession of the cable running through the territory of the Soviet Republic linking up with the cables of the company in other countries.

The amalgamation is announced of the three principal German cable companies, the Deutsche Atlantische having absorbed the Deutsche Süd Amerikanische and the Ost Europaische companies, at the same time raising its capital to 40 000 000 marks [nominally two millions sterling].

Although there was a decrease during the past year of over 3 000 000 in the number of passengers carried on the Bournemouth Corporation tramways, the annual report shows that a profit of £159 has been made, against a deficit in the previous year of £17 000. The small profit, despite increased fares, was due to reconstruction on main lines, fewer car miles run, the coal strike, trade depression, &c. The total traffic receipts showed an increase of £10 524, and working expenses were about £5 866 less.

Prices of Metals, Chemicals, &c.

Tuesday, May 9.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd, and the rubber prices by W. T. Henley's Telegraph Works Company.

Companies' Meetings, Reports, &c.

Siemens Brothers & Company announce a final dividend of 1s. per share, free of tax, making 10 per cent.

The Western Union Telegraph Company has declared a dividend of 1¾ per cent. on the common stock for the quarter, payable on July 15th.

Callenders Cable and Construction Company recommend a dividend of 15 per cent. (3s. per share, of which 1s. per share was paid on November 2) for 1921.

The directors of the English Electric Company recommend a dividend of 5 per cent. (less tax) on the ordinary shares, for the year 1921, payable on May 31.

The Lancashire Dynamo and Motor Company have declared a dividend of 1s. 3d. on the ordinary shares, making 2s. per share (10 per cent.), free of tax, for the past year.

The net profit of the Hart Accumulator Company for 1921 was £47 134, making with the balance of £25 616 brought in £72 750. The directors recommend a dividend of 11 per cent., subject to tax, on the ordinary share capital, carrying forward £54 341.

The receipts of the Cuba Submarine Telegraph Company for 1921 totalled £65 974, and expenses amounted to £33 009. After providing £8 502 for income tax and £9 334 for account of excess profits duty, there remains £15 127, plus the difference in exchange of £6 959 and £26 645 brought forward, making £48 732, less £15 000 added to general reserve. The directors recommend a final dividend on the ordinary shares at the rate of 5 per cent. per annum, and a bonus of 4s. per share, free of tax, carrying forward £16 532, subject to excess profits and other duties.

The accounts of Pinchin, Johnson & Company for the year ended December last, after providing for all expenses, depreciation, and taxation, show a net profit of £45 924, which, with £10 588 brought in, make available £56 512. Interim dividends on preference and ordinary shares absorbed £21 875, and the directors recommend payment of the half-year's dividend on the preference shares, a final dividend of 2½ per cent. on the ordinary shares (making 7½ per cent. for the year, against 15 per cent. the previous year), that the sum of £1 500 be written off for preliminary expenses of the new capital issue, and £16 512 be carried forward.

After charging administration expenses and including £2 305 brought forward, the accounts of the Bath Electric Tramways Company for the year ended December 31 last show an available balance of £17 433, from which the following amounts have been deducted :—£5 449 for interest on four and a-half per cent. first mortgage debenture stock, £1 000 for sinking fund, and £3 750 for dividend on preference shares, leaving a balance of £7 234. From this the directors have transferred £5 000 to contingencies and renewals account, and recommend that the balance of £2 234 be carried forward to provide for contingencies and replacements.

The total revenue for the year 1921 of the Gateshead and District Tramways Company amounted to £141 803. After deducting all expenses chargeable to revenue, including provision for renewals (£3 000), there remains a balance on the year's working of £43 818. To this is added £2 018, brought forward from 1920, making a total of £45 836. The directors recommend that £3 173 be placed to sinking fund for redemption of mortgages; to dividend for the year on £12 610 6 per cent. preference shares (on account of which 3 per cent. has been paid), £757; to dividend for the year on £120 000 5 per cent. preference shares (on account of which 2½ per cent. has been paid), £6 000; to dividend on the ordinary shares at the rate of 10 per cent. (on account of which 4 per cent. has been paid), £13 500, leaving £22 407 to be carried forward. The expenditure on capital account during the year amounted to £49 416, making the entire capital outlay upon the undertaking £412 342.

The report of the English Electric Company for the year ended December 31, 1921, shows that the net profits, after crediting dividends received from subsidiary companies, and amounts transferred from reserves previously set aside and no longer required, and after charging all expenses, amounted to £317 423. The amount brought forward from last year was £46 236, making a total of £363 659. After charging debenture interest £52 533, interest on 8 per cent. secured notes £100 000, trustees' fees £360, and preference dividends £41 914, there remains a balance available for appropriation of £168 852. The directors recommend the transfer to reserve for contingencies of £60 000, and a dividend on the ordinary shares (payable May 31, 1922) of 5 per cent. (less tax), absorbing £53 253, leaving a balance to be carried forward of £55,599 (as compared with £46 236 last year). Stocks of materials, &c., held by the company and its subsidiaries have been written down to current market values, or less.

The chairman of the Calcutta Electric Supply Corporation, Ltd., Lord Meston of Agra and Dunottar, K.C.S.I., who presided over the annual meeting on Tuesday, stated that the increase of capital expenditure from about £1 750 000 to nearly £2 250 000 reflected payments for new plant now on its way to India, which should shortly be producing increased revenue. The receipts from the sale of current showed a gratifying increase, being £414 000 in 1921 against £330 000 in 1920. The number of units sold had grown by only 11 per cent., and the surcharge mainly explained the balance. The continuing rise in the price of coal and in wages, coupled with the higher Indian taxation, had, however, more than absorbed the proceeds of the small surcharges. The net profit amounted to £217 000, against £263 000 in 1920. They had obtained welcome relief in the withdrawal of excess profits duty, and were able to maintain the dividend at 10 per cent. for the year, plus a bonus of 1 per cent., on a considerably increased share capital. The new capital had not yet earned its quota of revenue, but would commence to do so in the current year. Already there was a large and satisfactory increase of units sold. Ample provision had been made for depreciation and renewal of plant, and they had added substantially to the reserve and insurance funds. The past year was far from being free of difficulty; labour troubles occurred, but were wisely and successfully handled, and they had a competent and loyal staff. There were troubles over coal as to both quantity and quality, and increased expenses drove them to revise the scale of charges for power. Industrial unrest in this country had caused lamentable delay in the supply of new generating plant, of which they were in urgent need. Nevertheless, they closed the year in a stronger position than when it opened, and Major-General Mahon's timely visit to Calcutta went far to consolidate the good feeling between the Corporation and the Calcutta public. The demand for further services grew unceasingly, and they were only at the threshold of their possibilities.

New Companies.

G. Edward Carr.

G. Edward Carr, Ltd. (181 547). Private company. Reg. May 4. Capital, £12 000 in £1 shares. To adopt an agreement with G. E. Carr, and to carry on the business of electricians, manufacturers and repairers of and dealers in mechanical and electrical appliances and lamps, armature winders, &c. Subscribers: G. E. Carr, G. Y. Gray. Registered office: 560, Shields-road, Newcastle-on-Tyne.

Russell Electrical Appliances.

Russell Electrical Appliances Company. (181 431). Private company. Reg. April 29. Capital, £2 000 in £1 shares. To acquire and work a patent manufacture of electric meters under Electric Meter Patent No. 4 368/22, of which L. T. C. Russell is the sole patentee, &c. Permanent directors: L. T. C. Russell, W. G. Dewsbusy, and E. W. Jones. Secretary: Iden R. Reed. Registered office: 60, Queen Victoria-street, E.C. 4.

Woodstock Electric Light.

Woodstock Electric Light Company, Ltd. (181 541). Private company. Reg. May 4. Capital, £5 000 in £1 shares. To carry on business as indicated by the title, and to adopt an agreement with the Woodstock Electric Light & Power Company. Subscribers: G. W. Smith, J. H. Dew. Solicitors: Julius, Edward & Julius, 8, Old Jewry, E.C. 2.

Grosvenor Clark Electrical, Ltd.

Grosvenor Clark Electrical, Ltd. (181 548). Private company. Reg. May 4. Capital, £1 000 in £1 shares. Electrical engineers, manufacturers, and agents for the sale and purchase of electrical fittings and appliances, &c. Permanent directors: W. P. Grosvenor, J. A. Clark, W. Clement Drew. Secretary: W. Clement Drew. Registered office: 3-4, Great Winchester-street, E.C. 2.

Edmund Nuttall, Sons & Company.

Edmund Nuttall, Sons & Company, Ltd. (181 501). Private company. Reg. May 3. Capital, £100 000 in £1 shares. To take over the business of public works and general contractors carried on by E. Nuttall and J. Nuttall as "Edmund Nuttall & Company," to construct and equip railways, tramways, &c. First directors: E. Nuttall and J. Nuttall. Solicitors: Allen, Whitfield & Hodgson, 65, Princess-street, Manchester.

Holes, Ltd.

Holes, Ltd. (181 508). Private company. Reg. May 3. Capital, £1 500 in £1 shares. To adopt an agreement with S. H. Hole and C. Hole, and to carry on at Bursledon, Hants., or elsewhere the business of general engineers, manufacturers or repairs of all types of steam, electrical, or internal combustion engines or machinery, &c. First directors: N. H. Everitt, S. H. Hole, and C. Hole. Qualification: 100 shares. Registered office: 61, Union-street, Ryde, I.W.

Sunbeam Light Company.

Sunbeam Light Company, Ltd. (181 492). Private company. Reg. May 2 Capital, £250 in £1 shares. Agents for and dealers in electric lamps and light fittings, gas shades and fittings, oil and others lamps, &c. Life directors: A. P. H. van den Dorpel and Mrs. C. M. Thoenes. Registered office: 155, Praed-street, Paddington, W.

Welwyn Garden City Electricity Supply.

Welwyn Garden City Electricity Supply Company, Ltd. Reg. May 1. Capital, £25 000 in 23 500 preference shares of £1 each and 30 000 ordinary shares of 1s. each. First directors: Sir Theodore G. Chambers, J. R. Farquharson, C. B. Purdam, and Capt. R. L. Reiss. Secretary: F. J. Osborn. Solicitors: Grundy, Kershaw, Samson & Company, 6, Austin Friars, E.C. File number is 181 468.

Stamford Engineering Company.

Stamford Engineering Company, Ltd. (181 461). Private company. Reg. May 1. Capital, £1 000 in £1 shares. To acquire the business carried on by D. Stevens at 400, Hoe-street, Walthamstow, as the "Stamford Engineering Company," and to carry on business as general, electrical, and hydraulic engineers, &c. First directors: D. Stevens, Mrs. R. Stevens. Registered office: 400, Hoe-street, Walthamstow, Essex.

Tenders Invited and Accepted.

UNITED KINGDOM.

York Corporation. May 23.—Extension of electricity sub-station, Lendal-bridge York. Particulars from the City Engineer, Guildhall, York.

Kirkcaldy Electricity Works. June 5. Steam turbine three-phase alternator, condensing plant and piping. Particulars from Kennedy & Donkin, 17, Victoria-street, Westminster, S.W. 1.

Nottingham Corporation. June 9.—Manufacture, delivery, and erection at North Wilford Power Station of (Sec. D.) six fuel economisers, four steel chimneys, six induced draught fans, &c.; (Sec. E.) e.h.p. remote controlled main switchgear, &c.; (Sec. F.) three electric centrifugal pumps; (Sec. J.) one 75-ton overhead electric crane, one 10-ton and one 5-ton hand cranes; (Sec. K.) two 750 kW rotary converters, one 35 kW motor generator booster, &c. Particulars from Preece, Cardew & Rider, 8, Queen Anne's-gate, Westminster, S.W. 1.

Preston Electricity Undertaking. June 14.—Supply and erection of boilers, stokers, economisers, fans, chimneys, steam and feed piping and feed pumps. Particulars from the Town Clerk, Town Hall, Preston.

AUSTRALIA.

Victorian Government Railways. July 5.—* Supply and delivery of an industrial storage battery truck and battery charging equipment (Contract No. 35 028).

NEW ZEALAND.

Public Works Department. July 4.—* Manufacture, supply, and delivery, c.i.f. Auckland, of three 1 320 kVA single-phase transformers, complete with accessories (Section 56).

Willesden Urban Council have accepted the tender of British Insulated & Helsby Cables for twelve months' supply of cables.

Lambeth (London) Guardians have accepted the tender of the Express Lift Company for dismantling an existing lift and supplying an electric lift at Brook-street Infirmary, Kennington, at £953.

London County Council Education Committee have accepted tenders of A. Hawkins & Sons, at £718 10s., for wiring the Belleville-road school, and at £718 15s., for wiring the Wormholt-road school.

Battersea (London) Council have accepted the tenders of Ferranti Ltd., Chamberlain & Hookham, and Reason Manufacturing Company for meters for six months, and Dussek Bitumen Company for box compounds and bitumen composition for twelve months.

Stepney Borough Council have accepted the following tenders:—Sutton & Company, for the supply of one mile three-way 4-in. conduits, at £891; Burroughs Adding Machine, Ltd., for an electrically-operated adding machine, at £233 10s.; A. Reyrolle & Company, for 28 h.t. switches for Limehouse Generating Station, at £83 each.

Leyton Urban Council have accepted the tenders of Bruce Peebles & Company and A. Reyrolle & Company for motor converters and armour-clad switchgear, W. T. Henley's Telegraph Works Company for e.h.t. cable, Union Cable Company for tramway feeder cable, and Hackbridge Electric Construction Company for transformers.

The Philadelphia Electric Company has placed a large contract with the Westinghouse Electric & Manufacturing Company for air blast transformers, which includes sixteen 3 750 kV-A, single-phase transformers for operation at 60 cycles, with a total capacity of 60 000 kV-A. The total cost of the transformers will be approximately $100 000.

County Court Judgments.

[Note.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

ARROTA ELECTRICAL & MOTOR ACCESSORIES COMPANY, LTD., Charles-street, Louth, electrical and general engineers. £17 6s. Mar. 8.

BLAGDEN, Geo., 62, Weston-street, Sheffield, electrical engineer. £46 14s. Feb. 24.

JEFFERYES, A. N., 8, Denman-place, Piccadilly, W. 1., electrician. £21 17s. 10d. Jan. 30.

PAIN, J., 105, High-street, Hythe, electrical engineer. £19 10s. 4d. Mar. 2.

SEACOMBE, Jas., 98, Trevor-terrace, North Shields, electrician. £64 12s. 1d. Mar. 3.

THOMAS & EVANS, 4/7, Salubrious-place, Swansea, electricians. £59 16s. 6d. Mar. 8.

Bill of Sale.

[The undermentioned information is from the Official Registry. It includes Bills of Sale registered under the Act of 1822 and under the Act of 1878. Both kinds require registration every five years. Up to the date the information was obtained it was registered as given below; but payment may have been made in some of the cases, although no notice had been entered on the Register.]

ROBERTS, John Estall, 56, Garmoyle-road, Sefton Park, Liverpool, electrical engineer. May 6. £50.

Deed of Arrangement.

ROGERS, William, 136, Woodfield-street, and Dolcader House, Cwmbath-road, both Morriston, Swansea, electrical contractor. Filed, May 3. Trustee, S. E. Clutterbuck, 31, Queen-street, Cardiff. Liabilities unsecured, £667; assets, less secured claims, £323.

Mortgages and Charges on Limited Companies.

[Note.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

ELECTRICAL ENGINEERING (WEST BROMWICH), LTD. Registered April 21, £1 100 mortgage, to T. A. Nightingale, Bilhay-street, West Bromwich, iron merchant, and another: charged on land with Heath-cot., 402, High-street, West Bromwich. *Nil. Jan. 13, 1921.

MIDLAND COUNTIES ELECTRIC SUPPLY COMPANY, LTD. (late TRAMWAYS LIGHT & POWER COMPANY, LTD.), London, E.C. Registered April 27, trust deed dated April 25, 1922 (supplemental to trust deeds dated Feb. 26, 1914, Nov. 15, 1915, and April 14, 1919, securing £375 000 debenture stock); charged on 305 918 shares fully paid of £1 each and £56 785 5 per cent. debenture stock of the Derbyshire & Nottinghamshire Electric Power Company; 24 823 shares of £10 each fully paid in the Nottinghamshire & Derbyshire Tramways Company; 241 preference shares of £10 each and 6 747 ordinary shares of £10 each fully paid and £32 950 4½ per cent. first mortgage debenture bonds of and in the Leamington & Warwick Electrical Company Limited. *£344 150 (debenture stock), £200 000 (notes). March 15, 1921.

NORTHAMPTON ELECTRIC LIGHT & POWER COMPANY, LTD. Registered April 29, trust deed dated April 11, 1922, securing £40 000 debenture stock and premium at the rate of 5 per cent (no present issue); general charge. *£110 000. March 10, 1922.

Satisfaction.

MINEHEAD ELECTRIC SUPPLY COMPANY, LTD. Satisfactions registered April 28, £5 000, registered Dec. 9, 1907; and £5 000, registered Dec. 31, 1909.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Company Winding-up Voluntarily.

ANGLO-MEXICAN ELECTRIC COMPANY, LTD. R. R. Skelsey appointed liquidator. Meeting of creditors at 47, Parliament-street, Westminster, S.W. 1, Wednesday, May 17, at 3 p.m. Particulars of claims to the liquidator by June 1.

Liquidator's Notice.

ELECTRELLE, LTD.—Particulars of claims to T. R. Lawley, 24, Fountain-street, Manchester, the liquidator, by June 19.

Bankruptcy Information.

BATE, Douglas Clavell, 16, John Dalton-street, Manchester, electrical manufacturer and supplier. First meeting, May 17, 3 p.m., Official Receiver's Offices, Byrom-street, Manchester. Public examination, June 30, 10 a.m., Court House, Quay-street, Manchester.

Notices of Dividends.

BENNETT, William, Back Sitwell-street, Derby, electrical contractor. Amount per £, 1s. 1½d. First and final. Payable, May 10, 4, Castle-place Nottingham.

RAWSTHORNE, Thomas, 67B, Paradise-street, West Bromwich, Stafford, electrical engineer. Amount per £, 3s. 1½d. First and final. Payable, May 17, Official Receiver's Office, Ruskin Chambers, 191, Corporation-street, Birmingham.

Notices of Intended Dividends.

CAMP, William, Carr-lane, Slaithwaite, near Huddersfield, under the style of WILLIAM CAMP & COMPANY, electrical engineer. Last day for receiving proofs, May 20. Trustee: W. Durrance, 12, Duke-street, Bradford.

ROTHWELL, Peter, 64, Higher Bridge-street, Bolton, in partnership with Peter Ashworth Rothwell (a minor), under the style of P. A. ROTHWELL & COMPANY, electrical engineer. Last day for receiving proofs, May 13. Trustee, J. G. Gibson, Byrom-street, Manchester.

Partnerships Dissolved.

BARTLETT, Ernest William, and CROCKER, Stanley Cuthbert, electrical and mechanical engineers, 1, Pembroke-terrace, Cardiff, under the style of the HEATH ELECTRICAL & MECHANICAL ENGINEERING COMPANY, by mutual consent as from April 11, 1922. Debts received and paid by S. C. Crocker, who will continue the business.

BIBBY, Joseph, and MOTTERSHEAD, Fred, electricians, &c., 40, Park-green, Macclesfield, under the style of BIBBY & MOTTERSHEAD, by mutual consent as from March 31, 1922. Debts received and paid by J. Bibby.

BILL, William Harry, and BERRY, James Henry, electrical engineers and manufacturers' agents, at 18 to 26, Constitution-hill, Birmingham, under the style of BILL & BERRY. By mutual consent as from March 25, 1922.

DENYER, Frank, and HAYLER, Albert Waldegrave, electricians 89, Sackville-road, Hove, Sussex, under the style of DENYER & HAYLER, by mutual consent as from April 27, 1922. Debts received and paid by A. W. Hayler.

VISSENGA, John Williams, VANSON, William David, and NEWTON, Robert, electric welders, Queen Anne-road, Maidstone, under the style of the MAIDSTONE ELECTRIC WELDING COMPANY, by mutual consent, as from April 29, 1922. Debts received and paid by J. A. Robertson and W. D. Vanson, who will continue the business.

Bankruptcy Proceedings.

COOKSON, Eugene, trading as W. TURNBULL & COMPANY, at the Express Magneto Repair Works, Blackpool. Gross liabilities are stated to be £932 and the deficiency £630. At his public examination, held recently at Blackpool, debtor attributed his failure to expenses incurred in renovating business premises, pressure by creditors, and money paid for vacant possession of premises. The Official Receiver said debtor filed his petition owing to execution having been levied upon his effects. He was 23 years of age and unmarried, and before branching out in trade he was in the Army. On demobilisation he worked for a firm of electricians for three or four months, and in May, 1919, started on his own account. He then had £30 or £40 as his Army gratuity. He had three removals from premises, and at the time of the last one he had practically no capital, but he borrowed £375 from his friends, £50 of which had since been repaid. For the six months ending September, 1921, he made a profit of £25. He first became aware of his insolvency in March this year.

DICKEN, William John, trading as W. DICKEN & SON, 2, Upper High-street, Bargoed, Glamorganshire, electrical engineer. At his public examination this debtor, whose statement of affairs showed a deficiency of £130, stated that he commenced business at his present address in October, 1920, with about £550 free capital, his savings. The business had not paid from the outset, and as a result of the heavy outgoings and depression in trade, combined with the slump in prices, he had been unable to recover his position. He became aware of his position in January last. The examination was closed.

MAXIM LAMP WORKS, LTD., 75, Canonbury-road, Highbury, N. Under a winding-up order made against this company the statutory meetings of the creditors and of the contributories were held last week at the Board of Trade Offices, 33, Carey-street, W.C. A statement of affairs showing the position as at the date of the appointment of the receiver for the debenture-holders on July 28 last was presented, in which the liabilities were returned at £11 050, of which £4 987 were expected to rank, while the assets were estimated to realise £3 579, and consisted of the estimated surplus to come from the securities held by creditors regarded as fully secured. After payment of the preferential claims, £77, and of the loans on debenture bonds, £3 000, there was a sum of £502 available to meet the claims of the unsecured creditors, who were accordingly faced with a deficiency of £4 485. The company has created mortgages or charges, and on July 28 last Mr. Alfred Tosh, 75, Canonbury-road, N., was appointed receiver under powers contained in a debenture issued in July, 1918. The company was formed to acquire the business carried on by the receiver for the debenture-holders of the Maxim Lamp Works Electrical Company, Ltd., of Shernall-street, Walthamstow. The meetings resulted in the liquidation remaining in the hands of the Official Receiver. Appended is a list of the principal creditors: Duram, Ltd., London, £22; Edison & Swan Electric Company, Ltd., London, £87; General Electric Company, Ltd., London, £240; Imperial United Lamp Company, London, £474; Rose Bros., London, £10; Swan Electrical Company, London, £393; Stella Lamp Company, Ltd., London, £43; Scientific Metals Company, Ltd., London, £528; Tomey, F., & Company, Ltd., Birmingham, £261; Vactite Wire Company, Ltd., London, £26; Wiggins, H., & Company, Ltd., Birmingham, £12; Electric Lamp Supplies, Ltd., Birmingham, £156.

ROSLINGTON, William Henry, 240, High Holborn, W.C. This debtor formerly carried on business in partnership under the style of the GREENLING ELECTRIC SUPPLIES. The statutory first meeting of the creditors was held on Friday at Bankruptcy Buildings, Carey-street, W.C., when it appeared that in August, 1919, he became interested in a company, of which he was afterwards appointed managing director, but in April, 1920, he resigned, and the company had since gone into liquidation. During the time he was with the company in question he also carried on business in partnership under the style of the Greenling Electrical Supplies, into which as sleeping partner he put £100, his partner providing the experience. They each drew £10 a week from the business from Dec. 1, 1919, until the end of the following March. The partnership, which had been verbal, was dissolved by mutual consent in May, 1920, the debtor taking over the assets and liabilities of the business, although he had since ascertained that book debts of the face value of £1 000 were irrecoverable. He afterwards transferred the business to 240, High Holborn, and converted it into a limited company, called Greenling Electric Supplies, Ltd., with a nominal capital of £5 000. As vendor he was allotted 1 000 ordinary shares in payment of stock and contracts, and he was appointed managing director of the company at a remuneration of £500 per annum, plus director's fees, £100 per annum. Preference shares to the extent of £1 000 were taken up for cash. The debtor had, however, resigned his directorship and transferred his holding in the company to another person. He attributes his failure to the long illness of his wife and heavy expenses thereof, and to the lack of trade. His statement of affairs showed liabilities £1 209 and assets nil. The meeting passed a resolution for bankruptcy and the case remained in the Official Receiver's hands.

Arrangements for the Week.

FRIDAY, May 12th (to-day).

PHYSICAL SOCIETY OF LONDON.

5 p.m. At the Imperial College of Science, South Kensington. Demonstration of Some Electrical Properties of Neon-filled Lamps, by Mr. S. O. Pearson and Mr. H. St. G. Anson.

TUESDAY, May 16th.

INSTITUTION OF ELECTRICAL ENGINEERS.
(LIVERPOOL STUDENTS' SUB-CENTRE.)

3.45 p.m. At the University, Brownlow-street, Liverpool. Lecture on "Cheapening of Electricity Supply in Great Britain," by Mr. C. H. Wordingham.

THURSDAY, May 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

6 p.m. Savoy-place, London, W.C. 2. Kelvin Lecture on "Electricity and Matter," by Prof. Sir Ernest Rutherford.

JUNIOR INSTITUTION OF ENGINEERS.

6.30 p.m. At Monico Restaurant, London. Annual Dinner.

FRIDAY, May 19th.

INSTITUTION OF ELECTRICAL ENGINEERS.
(LONDON STUDENTS' SECTION.)

7 p.m. At Savoy-place, London, W.C. 2. "The Elimination of Atmospherics in Radio-Telegraphy," by Mr. A. H. Reeves.

Recent Wireless Publications.

Set out below will be found a series of references to, and short abstracts of recently published articles dealing with wireless telegraphic and telephonic communication. In order to facilitate reference these have been grouped under a few main headings indicative of the general subject matter discussed in the articles. References to British Patents on wireless subjects will be found included in our "Patent Record," which appears each week.

The very rapid growth of the volume of radio-literature published during the last few years is rendering more and more evident the need for some universal and internationally recognised system of classifying and referring to such publications. Quite recently the Bureau of Standards at Washington put forward some suggestions and subsequently issued a revised classification scheme based on the well-known Dewey decimal classification, the class number 621 384 assigned to Radio communication in that classification being for brevity designated by the letter R, followed by additional group numbers for the various branches of radio work.

Another extension of the decimal classification system to include the various branches of radio work has also been published in France by the Institut International de Bibliographie, but the sub-groups there defined are not in agreement with those set out by the Bureau of Standards. Other classification schemes have also been used in publications in this country and elsewhere.

The index headings in the following list have been arranged in accordance with the abridged classification put forward by the Bureau of Standards, as at the present time this appears to meet as well as any the requirements of the problem. The individual references have been grouped under the main headings of the Bureau of Standard's classification, but the group number of their abbreviated classification scheme is given at the end of each reference. Where the article in question deals with several branches of radio work these are indicated as far as possible by the addition of extra classification group numbers, these extra numbers being separated from the main classification number by a diagonal stroke. Thus should the need arise, the more complicated scheme will be incorporated in subsequent lists of references, since this can be done without in any way disturbing or rearranging the class groups in which the present references are arranged.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by Messrs. Mewburn, Ellis & Co., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

Complete Specifications.

146 997 Hogan, jun., J. L. Method of and apparatus for receiving radio-signals. (27/11/16.)
147 029 British Thomson-Houston Co., Ltd. Electric systems for the transmission of power, and multi-speed induction motors suitable for use therein. (31/5/17.)
147 533 Radio Corporation of America. Wireless signalling apparatus. (2/4/15.)
147 759 Latour, M. Telephone and the like systems. (25/6/15.)
147 793 Apple, V. G. Electric-current controlling devices. (17/1/19.)
147 853 Ges. für Drahtlose Telegraphie. Cascade high-frequency amplifiers. (22/7/18.)
148 314 Huth Ges., Dr. E. F. Manufacture and operation of vacuum tubes. (30/3/18.)
148 318 Huth Ges., Dr. E. F. Reels and the like for winding and unwinding aërial conductors. (16/1/18.)
148 446 Ges. für Drahtlose Telegraphie. Generation of high-frequency currents. (19/1/15.)
148 481 Majestic Electric Development Co. Electric heaters and the like. (26/12/17.)
148 529 Silbermann, H. Slip-pieces for bow collectors for electric vehicles. (1/9/15.)
148 976 Signal Ges. Electro-magnetic sound producers and receivers (14/8/18.)
150 354 Thompson, H. H. Electric arc lamps. (26/3/18.)
150 990 Union (Firm of). Automatic electrical chain-welding machine (2/9/19.)
151 003 Bisch Akt.-Ges. R. Magneto-electric ignition apparatus. (30/8/19.)
151 253 Soc. Anon. pour l'Exploitation des Procedes M. Leblanc-Vickers. Dynamo-electric machines. (18/9/20.)
152 001 Tanaka, T. Manufacture of electric rotating machines. (11/7/19.)
152 036 Ges. für Drahtlose Telegraphie. Means for receiving wireless signals. (8/10/19.)
152 617 Elektrische Gluhlampenfabrik "Watt" Akt.-Ges. Process for fastening the electrodes in vacuum tubes, more especially in Röntgen tubes. (18/10/19.)
153 004 Schmierer, M. Luminous electric discharge tubes for the production of illuminated signs and the like. (25/10/19.)
153 563 Western Electric Co., Ltd. Repeaters for multiplex signalling systems. (31/10/19.)
154 884 Ges. für Drahtlose Telegraphie. Transmission of high-frequency oscillations over high-power conductors for high-frequency telegraphy and telephony. (1/12/19.)
157 063 Electric Outlet Co. Inc. Electrical connecting and supporting devices. (10/1/20.)
157 095 Goosman, J. Electric gas lamps with glow discharge. (8/1/20.)
158 859 Hübener, H. Link-connecting piece especially for electroliers. (11/2/20.)
158 909 Soc. Materiale Elettro Trazione. Industrial process of and apparatus for the internal electro-plating of insulators. (12/2/20.)
164 009 Latour, M. Electro-magnetic wave-signalling systems. (8/12/15.) (Addition to 147 462. Divided Application on 147 462.)
166 521 Akt.-Ges. Brown, Boveri, et Cie. Mercury-vapour pumps for high vacua. (17/7/20.) (Addition to 165 400.)
170 612 Legge, W. A. Electric switch fuses. (29/4/20.)
170 614 Pouchain, A. Electrodes for electric batteries and accumulators. (3/5/20.)
170 615 Pouchin, A. Negative electrode for electric accumulators. (3/5/20.)
170 618 Pouchain, A. Electric accumulators. (27/5/20.)
170 619 Taylor, A. M. Electrical power transmission systems. (12/6/20.) (Patent of Addition not granted. Cognate Application 17 480/20, 22 617/20, 28 923/20, 31 156/20, and 2/21.)
170 634 Macrorie, A. K., Airey, H. Morris, Shearing, G., & Mullard, S. R. Insulation and support of thermionic valve electrodes between which a high potential difference exists. (10/7/20.)
170 643 British Thomson-Houston Co., Ltd. (General Electric Co.). Electric welding apparatus. (21/6/20.)
170 656 Marconi's Wireless Telegraph Co., Ltd. (Goldsmith, A. N.). Wireless telegraphy and telephony. (22/7/20.)
170 663 Cleaver, R. L. Dynamo-electric machine group. (24/7/20.)
170 692 Bowman, F. H., & Aspden, R. L. Transmission of power in and to the electrical equipment of motor-vehicles, aircraft, and the like. (6/8/20.)
170 701 Railing, A. H., & Angold, A. E. Means for charging portable electric accumulators. (11/8/20.)
170 716 Prentice, H. B. Ceiling roses, cut-outs, connectors, rosettes, and similar electrical fittings. (17/8/20.)
170 724 Zuckschwerdt, F. Electric switches. (20/8/20.)
170 728 Fawssett, E. Method and apparatus for the measurement of the temperature of electric cables. (23/8/20.)
170 730 British Thomson-Houston Co., Ltd. (General Electric Co.). Amplifying systems for electric currents. (23/8/20.)
170 735 Burns, P. C. Telephone desk sets. (7/9/20.)
170 738 Schlegell, F. von. Construction and regulation of electric arcs. (10/9/20.)
170 745 Rogers, T. W. (Krupp Akt.-Ges. F.). Electric switch devices. (21/9/20.)
170 746 British Thomson-Houston Co., Ltd. (General Electric Co.). Regulating systems for alternating current circuits. (22/9/20.)
170 748 Thompson, J. L. Storage battery testers. (27/9/20.)
170 751 Amberton, R. Casings, mountings, and connections for electrical instruments, such as ammeters. (30/9/20.)
170 756 Crust, R. Electric junction box. (8/10/20.)
170 768 Ham, A. W. Bases of trolley poles for electric traction. (2/11/20.)
170 784 McCrudden, H., & Callenders Cable & Construction Co., Ltd. Junction boxes for electric cables. (20/12/20.)
170 809 Turquand, F. J. Secret magnetic locks for electric battery lamps, more particularly for use in mines. (23/1/20.) (Divided application on 17 077/20.)
170 873 Damey, C. A. Electric fly switches. (29/4/20.)

THE ELECTRICIAN

ESTABLISHED 1861.

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

Electrical Engineering, Industry, Science and Finance.

No. 2296. [Vol. LXXXVIII No. 20.] FRIDAY, MAY 19, 1922. Prepaid Subscription U.K., £1 5s. per ann.; Abroad, £1 10s. Price 6d.

CONTENTS.

Notes of the Week.

An Interesting Scottish Water Power Scheme.

The Grampians Electricity Bill, the most important private measure of the Session, has emerged successfully from the Committee stage in the House of Commons, and we congratulate the promoters upon their diplomacy and tact in getting rid of the powerful opposition of the fishery and landed interests which at one time threatened to wreck the scheme. By judicious concessions the various opponents were induced to withdraw their petitions, with the result that the Bill is now proceeding as an unopposed measure. The powers sought include authority to use the water power of Lochs Rannoch, Ericht, Tummel and other lakes and rivers in the Grampians for the generation of electricity and to supply electricity in bulk, and also in retail, for power and lighting over a wide area. Four power stations are scheduled, but the scheme will be developed in sections, and the first power house will be probably erected at Loch Tummel.

Unusual Financial Provisions.

The Bill is also interesting on account of the proposed method of raising capital. The complete scheme is estimated to cost £4 500 000, but it was proposed to raise at the outset only £1 000 000 as share capital and £2 000 000 or £2 500 000 by debentures. This unusual method of finance, this unprecedented amount of borrowed capital, was severely criticised by members of the Committee, but as the promoters had secured from the Committee under the Trade Facilities Act a promise of a guarantee of the principal and interest on £2 000 000 of the debentures, it was ultimately decided to alter the clause by permitting the company to raise £1 750 000 in ordinary shares and £1 750 000 by borrowing. Of the latter £850 000 can be raised without the consent of the Electricity Commissioners, but their sanction must be obtained before the remainder can be borrowed. This seems to us a reasonable compromise under the circumstances, and will, we hope, ensure the passage of the measure through the House of Lords without further opposition.

Is State Guarantee Justified?

We do not appreciate the attitude of Mr. Briggs, M.P., one of the members of the Committee. He objects to a State guarantee in favour of a private enterprise, apparently because the commercial future holds a certain amount of risk. But the Trade Facilities Act was passed for the specific purpose of encouraging railway companies, electricity undertakings and others to carry out useful public works in order to increase employment, and we can conceive no scheme to be of greater public importance and utility than the Grampian Company's project. It will enable 50 000 or 60 000 E.H.P. to be developed from water power which is at present running to waste; it will assist by economising coal, by introducing new industries in the Highlands, by providing cheap power for operating the local railways, and in other ways. In our opinion there are few schemes more worthy of Government assistance than the Grampian hydro-electric project, which seems to contain no greater element of risk than some of those already approved by the Trade Facilities Committee. We are not enamoured of Government trading, but in certain cases, and the present is one of them, financial assistance might well be given for a limited period.

Three Important Wireless Points.

A second reading of Dr. W. H. Eccles' recent Paper on "Imperial Wireless Communication" clearly brings out three points. The first is that nothing is being

done to materialise an Imperial scheme except to talk about it. And to those who know the history of the attempts to bring a world-wide wireless communication into being, and who will recall the many Commissions and Committees which have reported and passed away and the expert knowledge which has been tapped and spilt, may well begin to wonder whether anything ever will be done. As in many other things, Great Britain was the first country successfully to achieve wireless communication. But now we are falling behind in the race, and shall continue to recede unless the problem is tackled in a more enterprising and broad-minded spirit. Government ownership and private monopoly are equally bad solutions, but something might be done with a combination of the two.

Patents and Progress.

The second point is the burning patent question. Dr. Eccles clearly brought out that the resources necessary for building the Wireless Chain do not all lie in one set of hands. For instance, probably the most vital patent of all, Fessenden's heterodyne patent, is owned by the Metropolitan Vickers Co., who are not usually looked upon as wireless people at all Again, Mullard silica valves are now in course of construction which will have about ten times the rating and about the same size as the largest Marconi valves; so there is freedom that way as well. C. F. Elwell has equipped many of the largest stations in America and Europe with masts and general wireless equipment; so there is no monopoly there. And altogether, as we pointed out last week, there is still that freedom of development which is essential for the good of so young an industry and science as wireless communication.

Is 2 000 Miles Enough?

The third point is that of range. Dr Eccles thinks that a 2 000 mile range is sufficient. The Marconi Company would have the range increased. But it is significant that no station of the size required under the scheme has yet been built even for the shorter of the two ranges, and the important question also arises whether it is economically sound to build a station which could maintain so long a maximum range as that suggested by the Marconi Company throughout the twenty-four hours. To do so would cost three times as much as to erect one of the official 2 000 mile stations, if it could be done at all, and would not offer any great practical advantages when it had been done, though it would perhaps be a magnificent gesture. On the other hand, the official relay stations will be utilisable for both long distance and local traffic, and will also be amply large enough to radiate a sufficient amount of energy for reception at practically every part of the earth at all times. If therefore, as seems probable, any advance is made with the design and construction of atmospheric limiting devices, the hours of working per day will be increased without the tremendous cost and added interference of the "super" station. But all these points are really insignificant so long as the Government shows reluctance to do anything. Mr. Kellaway has exhibited courage over the postal rates. Let him do the same with Imperial wireless communication. It is work that is long overdue. At present the position is most unsatisfactory, and Dr. Eccles' Paper and the discussion thereon have not improved it—unless it is by showing us how profound is the disagreement between acknowledged experts.

Improving Electric Traction Equipment.

It is axiomatic that electric traction must stand or fall on the economic results it brings in its train. These economic results will, we hope, be higher in many ways than the level we have reached to-day. One method by which this can be achieved is by an examination of all possible ways of improving the electrical equipment, whether it be on the locomotives, in the collecting arrangements or in the sub-stations. The Paper which Mr. Roger T. Smith read before a recent meeting of the Institute of Transport, and of which we publish an abstract elsewhere in this issue, is therefore opportune. Mr. Smith not only analyses the costs of employing present-day apparatus, but indicates ways in which that apparatus is being and may be improved so as to attain those results which we have just described as essential.

Railways and Electrical Manufacturers.

We are glad, moreover, to find him reiterating a point which he has made before. It is none the worse for reiteration, for it is in truth of the very greatest importance. In effect Mr. Smith asks whether it would not be better for the railways of this country to give a fair trial to the policy of helping to build up the manufacture of electric traction equipment by commercial firms rather than to try and manufacture that equipment for themselves, as they have done to a large extent in the past in the case of other engineering material. It seems to us that it is very much worth while. Not only would it help British firms to create and develop both home and foreign trade and all that that implies, but it would place at the disposal of the railway companies all those fruits of research and experience which are only attainable by those whose work it is to design and manufacture for a number of varying conditions, an experience which cannot be obtained by the railway electrical engineer, whose business is chiefly with maintenance. While therefore we have the greatest admiration for the work of British railway engineers, as evidenced in that almost perfect machine the modern steam locomotive, we hope that that policy of which that machine is the outcome will not be followed when a conversion to electric traction is undertaken. New ideas require new methods!

The Engineering Dispute.

Though at first sight the Court of Inquiry into the engineering dispute seems to have failed, owing to the lack of goodwill and good sense between the parties concerned, the prospects of a settlement of what has been a most disastrous misunderstanding are brighter as we go to Press than they have been at any time since the lock-out started. The fact is that Sir W. Mackenzie's report, if it did nothing else, at least raised in the minds of both disputants qualms as to the possibility of maintaining their stubborn attitude to the bitter end (whatever that is), and this combined with the war-weariness and disappointments which are the inevitable accompaniment of such occurrences, have induced a frame of mind which leads us to hope that some formula, bridge or datum will be found for getting out of the difficulty.

The Effect on Trade.

How necessary this is has probably been brought up to most of our readers in one or other forcible and unpleasant way. And the trade returns for April only emphasise the

disaster which has been gratuitously brought upon us Imports at 80½ millions are seven millions less than in the previous month, total exports are down by 10 millions, and exports of merchandise of home production by 9 millions. Exports of British manufacture were only 44 millions as against 51½ millions in March, and for this machinery with a decline of £1 600 000, and vehicles with a decline of £3 300 000, were largely responsible. The stoppage has indeed done harm from which the industry with which we are most concerned will be a long time in recovering. Its present state is pitiable, and makes the widespread assurances that trade is reviving seem cynicism of the worst kind in the ears of engineers.

An Important Development.

In a preceding paragraph we remark that the name of the Metropolitan Vickers Electrical Company is not much associated with wireless work. But that is to be changed, for we are now able to announce that that well-known concern is entering this field in conjunction with the Radio Communication Company, of London, and is taking active steps towards the manufacture of wireless receiving equipment. It will be remembered that the Radio Communication Company was formed in 1919 to conduct business in connection with the establishment of radio telegraph and telephone installations, and is well known for its important work in this connection during the war. The company is also connected with the Indo-European Telegraph Company and the Eastern Telegraph Company.

Wireless at Trafford Park.

Mr. A. P. M. Fleming, the manager of the Metropolitan-Vickers Company's research and education departments, has been for some time in touch with the Postmaster-General with reference to the establishment of broadcasting stations. The precise areas to be covered by the different stations have not yet been defined, but there is little doubt that the Metropolitan-Vickers Works at Trafford Park will form the site for the Manchester district station, and a second station will probably be located at Slough, other stations being projected as they are required. Immediately details respecting the sites and areas to be covered are settled it is expected that the work will go ahead quickly and the manufacture of receiving sets is already being pushed forward. It will be recollected that the Metropolitan-Vickers Company is technically very closely associated with the Westinghouse E. & M. Company, of Pittsburgh, which was the pioneer of radio broadcasting in the United States, and among the first of the companies to undertake the extensive manufacture and distribution of cheap equipments for the reception of broadcasted news, musical programmes, weather reports, etc. The Metropolitan-Vickers Company will therefore be able freely to draw upon this unique experience, and this together with the technical experience of the Radio Communication Company, and its own selling, manufacturing and research organisation, should place the Company in a favourable position in entering this new field. Further developments will be awaited with interest.

Illegal Connections to Supply Mains.

A number of charges of stealing electricity and of making unauthorised connections to the mains of supply authorities have been before the police courts of late, and the question arises whether the penalties for an offence, which is evidently on the increase, are sufficiently severe to act as a deterrent. We reported two cases a fortnight ago in The Electrician and one in the issue before that. Two of the parties were fined, one £5 and the other £50, but it is doubtful if courts of petty sessions can appreciate the situation, or realise the damage that may be done by these illegal connections, because the penalty seldom exceeds £5.

The Law on the Subject.

By Sec. 23 of the Electric Lighting Act of 1882, any person who maliciously or fraudulently abstracts, causes to be wasted or diverted, consumes or uses any electricity is guilty of simple larceny, and punishable accordingly. It is not always easy to prove felonious intent against a householder who employs a contractor and relies on him to make the connection to the mains, and, moreover, the expense and trouble of prosecutions are so great that usually recourse is had to the limited summary jurisdiction of magistrates. Consequently, charges of illegal connection are brought under sections of the Gasworks Clauses Acts, 1847 and 1874, which have been incorporated in the Electric Lighting Act, 1882, and which limit the penalty to £5 for each offence, though the undertakers may also recover the amount of any damage sustained by them.

An Inadequate Punishment.

This is an inadequate punishment, for an unauthorised electricity supply connection may be far more serious in its consequences than the tapping of a gas main, as it might blow a fuse and lead to many neighbouring consumers being deprived of electricity. Serious cases of fraud on supply authorities should be sent to the Quarter Sessions, where heavier penalties could be inflicted, and we also think the law should be altered to enable undertakers to charge the consumer with the value of the maximum amount of electricity which the lamps and other current-consuming devices on his premises could have consumed. Contractors who lend themselves to these illegal acts should equally be penalised, so that a stop may be put to dishonest and mischievous practices.

The Rivals.

The recent debate in the House of Lords on the Electricity Supply Bill brought out a question of principle in regard to legislation for the rival industries—electricity and gas. Lord Newton, it will be remembered, put forward an amendment in the interests of gas companies which Viscount Peel suavely but summarily disposed of, explaining that it has not been customary to allow gas companies a *locus standi* on Electricity Bills simply on the ground of competition, or to allow them the right to veto electricity supply. The gas companies, in their view of the present Bill, are evidently more optimistic as to the benefits of electricity supply legislation than a certain section of the electricity supply industry itself. This reminds us of a semi-obsolete provision in the Electric Lighting Act of 1882, which probably most people have forgotten. Everyone at that time was exceedingly optimistic as to the vast conquest which electricity would make when once suitable legislation was provided (they have learnt better since), and the framers of the Act of 1882 anticipated an early demise of their gas rivals in certain localities. Under Section 29 of the 1882 Act, Parliament therefore very considerately provided that in any area where electric light ousted its rival to such an extent that the supply of

gas was unremunerative, the gas company could make application to the Board of Trade to be relieved of its obligations to supply gas in such areas, and the Board of Trade was empowered to give them such relief. But only in one or two small areas have gas companies hauled down their flag, though many of them have obtained electricity supply powers in order to keep out rivals. Usually where a gas company supplies gas and electricity it will be found that, owing to the novercal attitude of the company, no attempt is made to push the use of electricity, and this side of the business is in a chronic state of bankruptcy. If, however, our good friends, the gas industry, feel alarmed at the present legislation, they have the comfort that the 1882 Act provides for their respectable and dignified obsequies.

A New Zealand Electricity Scheme.

INTERESTING particulars of the progress made in the evolution of the national scheme of electricity supply for the Dominion of New Zealand are given in the annual report for 1921 of the Chief Electrical Engineer, Mr. L. BIRKS. Drawn up in 1916 by Mr. E. PARRY, the scheme was based on the gradual development of the water power available in both islands and the estimated demand was put at 0·2 H.P. per head of the population per annum. In order to supply this power for the North Island a complete interconnected scheme was laid out, consisting of 1 112 miles of main transmission lines and 309 miles of branch lines. The pressure adopted was 110 000 V for main transmission and 33 000 V for branch lines, except the Waikato branch, where a pressure of 50 000 V was already in operation from the Horahora station. The system is to be connected up and fed from three main hydro-electric stations—viz., Mangahao River (24 000 H.P.), Waikaremoana (40 000 H.P.) and Arapuni (96 000 H.P.), but the ultimate capacity of these stations will be 322 000 H.P. and the transmission lines are to be connected up to three existing plants of 12 000 H.P. at Horahora, New Plymouth and Wairua Falls. The cost of the whole North Island system was originally estimated at £7 303 042, but this figure will be exceeded by over 50 per cent., and already authority has been given to raise £9 322 500. And the ultimate cost of the schemes for the Dominion will be over £20 000 000.

Progress During 1921.

During the past year the Horahora plant and main transmission line to Waihi (50 miles) were purchased for £212 500 and it is proposed to extend the generating plant by two units of 2 600 H.P. each, bringing the total capacity of the plant to 13 600 H.P. Supply was commenced in Cambridge, Hamilton and Paeroa; lines were erected to Te Awamutu and Te Aroha, and the necessary material was ordered for the first of the 110 000 V main lines to Auckland, which is now receiving a temporary supply from Horahora. Some progress was also made with the Mangahao station, but tenders for the plant were not invited until the end of the year in order to obtain the advantage of lower prices. During the current month, however, the Metropolitan Vickers Electrical Company secured this important contract, which includes three 6 000 kVA and two 3 000 kVA water wheel generators, switchgear, transformers, &c. In addition, the approach roads and bridges at Waikaremoana are being constructed and power house surveys made, and at Rotorua the surveys have also been completed. The total expenditure on all the North Island projects at March 31, 1921, was £457 974, compared with £201 723 in the previous year.

South Island Scheme.

No comprehensive plan has been drawn up for the supply of the South Island, but sufficient information is now available to enable the general outlines to be laid down for the Canterbury, Otago and Southland portions of the Island. The scheme will consist ultimately of a completely inter-connected transmission system on somewhat similar lines to the North Island and supplied from four or five main power houses and two or three subsidiary sources. As the population in the South Island is more concentrated round certain definite centres and as the transmission pressure already adopted for the Lake Coleridge and the proposed Southland system is 66 000 V, it is proposed that this shall be the standard employed. This is stated as being the highest pressure for which pin insulator construction is reliable, and will effect a saving of £400 per mile in first cost, compared with the 110 000 V suspension insulator type. For Canterbury, Otago and Southlands 759 miles of main transmission lines are suggested, but a few isolated districts will be dealt with separately. The various power boards or retail authorities will be supplied in bulk from the main lines; sub-stations will be located at intervals of 20 to 60 miles, according to the demands, and from these sub-stations supply will be given to the power boards at 11 000 or 33 000 V.

Financial Results.

Some particulars are given of the operating results of the Horahora and Lake Coleridge undertakings, the two main Government supply systems, and of the local electric supply undertakings. The capital outlay at Horahora was £249 745; the total costs were £21 004; the revenue amounted to £14 663, and there is an accumulated debit balance of £8 464. The total units sold were 15 376 000, of which the Waihi Gold Mining Company took 14 477 387. On the Lake Coleridge scheme the capital expenditure was £499 957 (against £422 076 in the previous year); the year's revenue was £51 373, working expenses came to £21 341, capital charges to £18 639, and after allowing £7 946 for depreciation there was a net profit of £3 447. The total units sold were 31 402 351 (compared with 28 017 976), costing 0·366d. per unit, but the price received was 0·288d. from Christchurch City Council (14 700 000 units), 0·294d. from the tramways (6 379 717 units), 0·553d. from wholesale consumers and local bodies (10 051 734 units) and 1·58d. per unit from retail consumers, who took only 270 000 units. The power house maximum showed an increase of 6½ per cent., the output an increase of 10 per cent., and the load factor improved from 59·9 to 61·4 per cent.

Low Prices General.

The prices charged seem to be low and they compare favourably with the best of the British undertakings. Yet a profit was made on the year's working, and no doubt better results will be shown when the system is fully developed.

A new 3 000 kW generating set was started up, and various extensions of the transmission lines, distributing networks and sub-station equipment were carried out during the year. The total connected load (34 277 kW) increased by 12½ per cent., and the very high diversity factor (5·1) is

attributed to the encouragement of off-peak loads. The transmission line insulators have given indications of progressive deterioration and during the latter part of the year breakdowns occurred, but a rigorous overhaul and replacement of defective insulators have effected a pronounced improvement. Of the fifteen councils and public bodies taking energy in bulk and retailing it to the public, nine made an aggregate profit of £11 821 and six recorded a total loss of £725. This seems satisfactory, especially as those which made a loss were all small and undeveloped undertakings.

Local Supply Systems.

Apart from the two Government hydro-electric works, there are 55 supply stations in the Dominion. The total capacity of these 57 stations is 49 630 kW of main plant and 5 831 kW of subsidiary plant. There are 26 hydro-electric stations of 23 895 kW (48·1 per cent. of the whole); 10 steam-driven of 21 820 kW (44 per cent.), 19 gas engine stations of 3 195 kW (6·45 per cent.) and two oil engine stations of 720 kW (1·45 per cent.). Seven additional licences for local distribution and one licence for bulk supply were issued during the year and construction is in hand, but only slight additions were made to the total plant capacity. It has, however, been decided to put in new plant of 45 000 H.P., at an estimated cost of about £1 600 000, and work on these extensions is proceeding.

Consumers and Units Sold.

Pending the completion of the large Government hydro-electric stations some of the existing smaller plants are being linked up and it is hoped that this will enable the various authorities to carry on until the larger sources of power are in operation. At the end of the year there were 73 151 consumers, compared with 58 449 in the previous year; the total length of "reticulation" lines is 2 260 route miles and of transmission lines 360 miles. The units generated by the 57 power plants amounted to 149 476 379, of which 124 446 459 were sold. The units sold per consumer, after deducting the tramway supply, were 1 246, or 133 per head of the population. These figures are above the average for British provincial undertakings, and when the sparsely populated, rural character of many of the supply areas in New Zealand is taken into account, the record is quite good.

The Agricultural Demand.

Dairy farming is, and promises to remain for some years, the main industry of the Dominion. Consequently, the future of electricity supply is bound up with the extension of the distributing system into the dairy districts. The organisation of electric power boards is proceeding in a satisfactory manner and four new boards were formed in 1921, making fourteen in all and covering nearly 19 000 square miles, or over 18 per cent. of the total area of the Dominion. The importance of the dairy demand is seen from the fact that there are about 40 000 milk suppliers, and in April 1920 nearly 9 000 of these were using milking machines, requiring 2 to 3 H.P. each; and according to Mr. BIRKS the number is increasing at the rate of 16 per cent. per annum. The total demand for milking alone will thus run into tens of thousands of horse-power, and will constitute a large proportion of the total demand for hydro-electric power in the Dominion.

Economics of Country Lines.

It is calculated that there will be a revenue of £24 to £30 from the average dairy farm for milking machines alone. This figure will justify the laying of a supply line, and when once electricity is available on the farm it is probable that it will be used for lighting, ironing, cooking, heating and power generally. In view of the difficulty of making country lines remunerative, tests were recently carried out on five typical plants in the Canterbury district in order to determine the power required to drive the average plant and the consumption of energy over a season. A 3 H.P. motor was employed, but as the tests indicated that a 2 H.P. motor would have been sufficient for at least four of the test installations, 2 H.P. motors have been installed on several similar and even larger plants, with satisfactory results.

Standardization of the Milking Machine.

This size is in fact being standardized for milking machine drives generally. The results of the tests are set out in a table in a paper by Mr. BIRKS, which has been reprinted from the "New Zealand Journal of Science and Technology," and the conclusions to be drawn from the table are: (1) The low power required; (2) the high value of the idle current and the consequent high value of kilovolt-ampere demand; and (3) the power taken is very variable and apparently depends more on the efficiency of the plant and method of use than on the actual number of cows milked.

Milking Demand an Ideal Load.

From the point of view of the supply authority the milking load is said to be ideal, as the heaviest load occurs in the summer, when no overlapping of lighting and power peaks of the main system is likely, and it tapers away almost to zero for the three worst winter months, when the general demand is highest. Even in summer the milking plant is finished before 8 a.m., and is not required again until 5 p.m.; thus the industrial or day peak is not interfered with, and it allows an undertaking to work on a higher diversity factor, produces a better load factor and tends to flatten out the daily load curve, at the same time yielding a substantial revenue. Once electricity is available in the milking shed it will also be used for heating water and other purposes, and in the opinion of Mr. BIRKS the most effective application of electric power to milking machine work will consist of a small self-contained outfit comprising the electric motor, a vacuum pump, a cream separator, a small water supply pump and 10-gallon hot water cistern, with the necessary switchgear, all mounted on a compact hardwood base plate, suitable for moving about.

A Contrast.

Units such as these are said to be required by the thousand in the dairying districts of the Dominion, and British manufacturers who are in a position to supply them might well take note of the fact, as there is no part of the Empire so favourable to British manufactures than New Zealand.

This is sufficient to show that they are optimists in New Zealand, and are not oppressed by doubts as to the financial results which will be obtained from the widest possible use of electricity on farms.

In general, therefore, it may be said that electricity supply is being conducted on modern lines in the Dominion, and in some respects is in advance of what has been done in this country. One of these seems to be the whole-hearted efforts that are being made to establish a wide-spread system of electricity supply on most modern lines. It is significant that it is in the newest countries that the public good is the first endeavour and that only in the older kingdoms is obstructionism permitted to hold sway to any extent.

Some Notes on the Theory of Phase Meters.

By G. W. STUBBINGS, A.M.I.E.E., A.Inst.P.

The author considers in detail a theory of single phase and three phase meters which is on simpler lines than the usual analytical treatment. The resultant rotating field, pulsating fields, frequency errors, accuracy and the advantages of balanced load power factor meters are discussed.

The present paper is an attempt to put forward a brief account of the theory of phase meters which will be on simpler lines than the usual analytical treatment, whilst being somewhat more rigorous than the perfunctory treatment generally accorded to this subject.

The Single Phase P.F. Meter.

The single phase power factor meter is the simplest instrument of its class for a preliminary elementary consideration. The moving element of this instrument consists of two coils spaced at right angles and pivoted without control, these two coils being of similar size and number of turns, and traversed by equal currents proportional to the voltage of the supply, one of these currents being in phase with, and the other displaced in phase by 90 degrees from this voltage. The fixed coil of the instrument is traversed by the current the phase of which is to be determined. The moving element gives rise to a uniform rotating field. If time be reckoned from the instant that the direction of the rotating field coincides with the axis of the coil in the non-inductive pressure circuit, and θ be the angle between the axis of this coil and that of the fixed coil measured in a direction against the rotating field, the position of the rotating field with respect to the fixed coil at any instant will be $(pt-\theta)$. The torque on the moving system is therefore proportional to

$$iv \cos(pt-\varphi)\sin(pt-\theta)$$

or to $$iv\{\sin(2pt-\varphi-\theta)-\sin(\theta-\varphi)\}$$

Since the moving system is without control it will take up a position such that the average torque is zero. The average value of the first term in the above expression being zero, this condition is given by $\sin(\theta-\varphi)=0$ or $\theta=\varphi$ The angle between the axes of the fixed coil and the non-inductive coil of the moving system will therefore be equal to the phase angle of the current with respect to the voltage.

An Alternative Consideration.

An alternative method of deducing the foregoing result is to make use of the elementary proposition that a field oscillating according to the simple harmonic law can be resolved into two equal fields rotating in opposite senses. These rotating components coincide in direction when the resultant field passes through its maximum values. According to this conception the non-inductive coil of the moving system of the power factor meter gives rise to two rotating fields. The reactive coil will similarly have two rotating components. The current in this coil being displaced 90 degrees in phase with that in the non-inductive coil, at the instant the two rotating components of this latter coil coincide in direction the two components of the field due to the reactive coil will be spaced 90 degrees from it. The angular spacing of the components of this field with respect to the coil producing it will, of course, be in opposite senses, since these components are rotating oppositely. One of these components will, therefore, coincide in direction with the similarly rotating component of the non-inductive field, whilst the oppositely rotating component of the reactive field will be 180 degrees displaced from the similarly rotating component of the other coil, and these components will cancel each other.

Uniform Resultant Field.

The total resultant field will, therefore, be uniform in magnitude, and will have a constant angular velocity. The fixed coil will likewise give rise to two rotating components, the one of which rotating in the opposite sense to the field due to the moving system will not be competent to produce any average torque. The component which rotates in a similar sense to that of the pressure field, has its direction coinciding with the axis of the fixed coil when the current passes through its maximum value. At the instant therefore that the pressure field coincides in direction with the axis of the coil connected in the non-inductive circuit, the similarly rotating component of the current field will be at an angle φ from the axis of the fixed coil, φ being measured against the direction of rotation for a lagging current and *vice versa*. If θ have the same meaning as before, at the instant considered, the angle between the direction of the two fields is $(\varphi-\theta)$, and since they are rotating uniformly at the same angular velocity, this angle remains constant. The torque on the moving system being proportion to $\sin(\varphi-\theta)$ this system will take up a position such that this torque is zero and the direction of the two similarly rotating fields is coincident.

Case of Two Coils at 90 deg.

The resultant rotating field produced by a set of coils in a power factor meter is not in constant in magnitude, nor uniform in angular velocity. The extremity of the resultant flux vector describes an ellipse which in limiting cases becomes either a circle or a straight line. The properties of an elliptical field can be briefly noticed by looking at the simple case of two coils spaced 90 degrees apart, carrying unequal currents displaced 90 degrees in phase. If x and y are the instantaneous values of the two pulsating fields, the locus of the extremity of the resultant flux vector is given by

$$y=b\sin pt \qquad x=a\cos pt$$

whence $$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1.$$

The angle described by the resultant flux vector is given by

$$\tan\beta=\frac{b}{a}\tan pt.$$

The magnitude of the resultant flux is $F=(x^2+y^2)^{\frac{1}{2}}$.

The angular velocity of the resultant vector is given by

$$\frac{d\beta}{dt}=\cos^2\beta\,\frac{pb}{a\cos^2 pt}$$

or, since $$\cos^2\beta=\frac{a^2\cos^2 pt}{F^2}$$

$$\frac{d\beta}{dt}=\frac{pab}{F^2}$$

The rate of increase of the area swept out by the flux vector is

$$\tfrac{1}{2}F^2\frac{d\theta}{dt}=\frac{pab}{2}$$

The movement of the rotating resultant is such that the flux vector describes equal areas in equal times. The angular velocity is thus less than the average when the direction of the resultant is in the neighbourhood of the stronger coil and greatest when passing the axis of the weaker.

Torque on the Moving System.

The torque on the moving system of a power factor meter which generated such an elliptical field would have the average value of

$$iF\sin(pt-\varphi)\sin(\beta-\theta).$$

The direct calculation of the value of θ which makes this average value zero, is troublesome, but by resolving the pulsating fields into rotating components, the calculation is much simplified. Considering the case just discussed. if $2a$ represents the maximum value of the pulsating fields due to the non-inductive coil of the pressure, and $2b$ that of the reactive coil, the two fields differing in phase

by 90 degrees; the components rotating in one sense will reinforce, and those rotating in the opposite sense will oppose each other. The values of these components will be respectively $(a+b)$ and $(a-b)$. The rotating components of the field due to the current coil will, at the instant the stronger pressure field coincides in direction with the axis of the non-inductive coil, be distant from the axis of the series coil by an angle φ measured against the direction of rotation of each field. If the angular displacement of the moving system as previously defined be θ, then at this instant the angular distance between the pairs of similarly rotating components will be $(\varphi-\theta)$ and $(\varphi+\theta)$ respectively, and the torques produced by these pairs of components will be opposite in sense, and the resultant torque is

$$(a+b)\sin(\varphi-\theta)-(a-b)\sin(\varphi+\theta).$$

When this torque is zero

$$\tan\theta=\frac{b}{a}\tan\varphi.$$

Nature of the Frequency Error.

This expression gives the nature of the frequency error for a single phase power factor meter having the reactive circuit in the form of a condenser. The phase displacement in such a case will be very nearly 90 degrees, and the effect of frequency is only to alter the value of the current in the reactive circuit.

When the reactive circuit of a single phase power factor meter is inductive it is not usually possible to obtain a much greater phase displacement than 80 degrees. If the actual angle be $(90-\alpha)$ degrees, and the maximum values of the two fields be equal, then the component of the reactive field which tends to reinforce the similarly rotating component of the non-inductive field will be α ahead of it, whilst the oppositely rotating component of the reactive field will be $180+\alpha$ in advance of that of the non-inductive field

If a be the maximum value of the two fields, the resultant of one pair of components will be $a\cos\frac{\alpha}{2}$, which is $\frac{\alpha}{2}$ ahead of the axis of the non-inductive coil when the field of this coil is a maximum, the resultant of the other pair being $a\sin\frac{\alpha}{2}$, $90+\frac{\alpha}{2}$ in advance at the same time. The resultant torque is

$$\alpha\left\{\cos\frac{\alpha}{2}\sin(\varphi+\frac{\alpha}{2}-\theta)-\sin\frac{\alpha}{2}\cos(\varphi+\frac{\alpha}{2}+\theta)\right\}$$

When this resultant torque is zero

$$\cos\frac{\alpha}{2}\sin(\varphi+\frac{\alpha}{2}-\theta)=\sin\frac{\alpha}{2}\cos(\varphi+\frac{\alpha}{2}+\theta)$$

giving

$$\sin(\varphi-\theta+\alpha)+\sin(\varphi-\theta)=\sin(\varphi+\theta+\alpha)-\sin(\varphi+\theta)$$

and $$\cos(\varphi+\alpha)\sin\theta=\sin\varphi\cos\theta$$

finally $$\tan\theta=\frac{\sin\varphi}{\cos(\varphi+\alpha)}.$$

When $\varphi=90$ degrees, corresponding to zero power factor lagging, $\tan\theta=-\operatorname{cosec}\alpha$, and θ is greater than 90 degrees. With zero power factor leading θ is less than 90 degrees. The scale is, therefore, opened out on the lagging side and cramped on the leading side. The best compensation for the lack of quadrature of the two fields is to space the two coils of the moving system in such a manner that the backward rotating field is eliminated. If the axis of the reactive coil be $90+\alpha$ degrees in advance of that of the non-inductive coil, reckoning this angle in the direction of rotation of the principal field, the backward rotating components will be at 180 degrees and will cancel. A pure rotating field will, therefore, be produced, the axis of the non-inductive coil of the moving system being displaced α degrees from the axis of the series coil at unity power factor.

The Three-Phase Power Factor Meter.

The three-phase power factor meter for unbalanced loads utilises two rotating fields which are produced by three sets of coils, each spaced at 120 degrees, excited respectively from the voltage and the current of the three-phase supply. Assuming a symmetrical voltage system the currents in the three pressure coils will be equal, and will differ in phase by 120 degrees. At the instant that the current in one of these coils is passing through its maximum, and the two rotating components of the field that it produces coincide in direction with its axis the components of the other two coils rotating in one sense will have a phase angle of advance equal to their physical angle of lag, and will, therefore, at the instant considered coincide in direction with the similarly rotating components of the first coil. The oppositely rotating components of the second two coils will have their phase angle of advance added to their physical angle of advance and will therefore be spaced

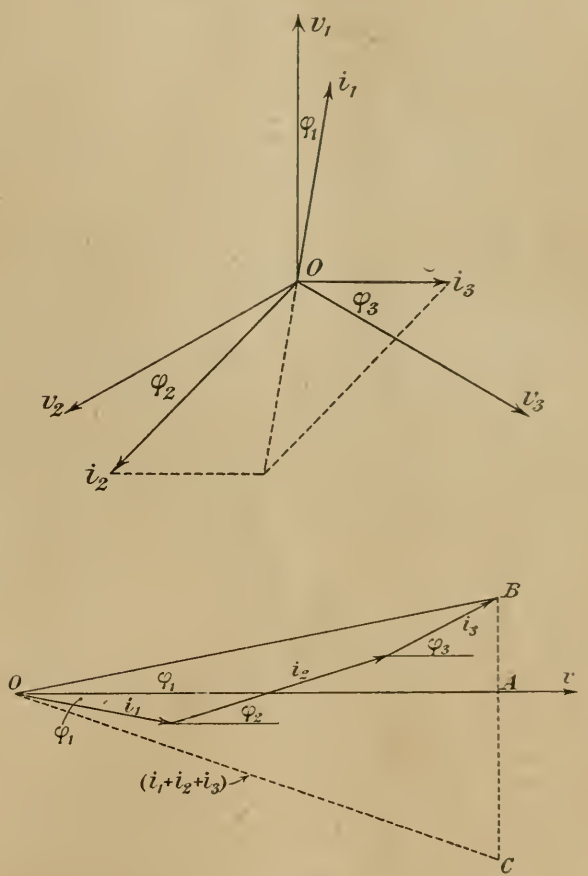

FIG. 1.

240 and 480 degrees from the corresponding component of the first coil. The three components of this latter sense of rotation will, therefore, be spaced at 120 degrees and their resultant will vanish. The voltage coils, therefore, give rise to a pure rotating field. The forward rotating components of the current coils will, due to their physical spacing, be displaced φ_1, φ_2, and φ_3, from the axis of the coil carrying the current in phase 1. The backward rotating components of the current system will give rise to no torque, since there is no voltage component of similar sense with which it can combine. If θ be the angular displacement between the axes of corresponding current and pressure coils the resultant torque on the moving system is proportional to

$$v\{i_1\sin(\varphi_1-\theta)+i_2\sin(\varphi_2-\theta)+i_3\sin(\varphi_3-\theta)\}$$

This is zero when

$$\tan\theta=\frac{\Sigma i\sin\varphi}{\Sigma i\cos\varphi}.$$

If the instrument is scaled to indicate cos θ the power factor so given is

$$\cos\theta = \frac{\Sigma i \cos\varphi}{\{(\Sigma i \sin\varphi)^2 + (\Sigma i \cos\varphi)^2\}^{\frac{1}{2}}}$$

The meaning of this value of the power factor of an unbalanced three-phase circuit is shown in Fig. 1. The upper diagram indicates vectorially the phase relationship of the circuit, the lower diagram showing the summation of the power and wattless volt amperes in each phase. OA represents the total power, and AB the wattless component. The quantity OB, which represents

$$v\{(\Sigma i \sin\varphi)^2 + (\Sigma i \cos\varphi)^2\}^{\frac{1}{2}}$$

is in general less than the actual volt-amperes Σiv. In the diagram the actual volt-amperes are represented by OC and the power factor of the circuit as given by the relation $\frac{\text{power}}{\text{volt amperes}}$ is $\frac{AC}{OC}$.

Accuracy Dependent on Voltage Balance.

The theoretical accuracy of the indication of the power factor of an unbalanced three-phase circuit as previously defined, by a six-coil power factor meter, depends upon the voltages of the three lines being balanced. It has been shown by Gifford* that such departures from balance in the voltage system as are likely to be met with in practice, affect the accuracy of indication of such a power factor meter to an extent so small as to be negligible.

Three-phase power factor meters are frequently constructed with four coils only for use in circuits that are approximately balanced. Such instruments are of two classes, the one having three voltage and one current coil, and the other, three current and one voltage coil. The type with three voltage coils has, if the voltage be balanced, a uniform rotating pressure field, and such an instrument will, it is obvious, indicate the phase angle of the particular current supplying the series coil with respect to the corresponding star voltage. The inaccuracy of such an instrument on unbalanced loads will therefore depend upon the line in which the series coil is connected.

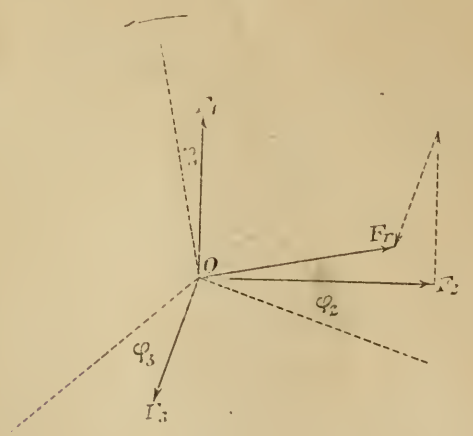

Fig. 2.

There are advantages in constructing balanced load power factor meters with one pressure and three current coils, since this type is more suitable for the inductor principle in which conducting ligaments are eliminated, and a 360 degree rotation of the moving system is possible. In such an instrument the backward rotating components of the fields due to the series coils will combine with the similarly rotating component of the single pressure field to produce a torque that will introduce an error in the indications of the instrument if the circuit is unbalanced. The nature of the backward rotating resultant field in such an instrument is worthy of note. The physical angular spacing of the coils is added to the angles of phase displacement to obtain the relative position of the three components. These components will, therefore, be displaced φ_1, $240-\varphi_2$, and $480-\varphi_3$ from the axis of reference. The spacing of these components for the circuit represented in Fig. 1 is shown in Fig. 2 by OF_1, OF_2, and OF_3. These three vectors are not in equilibrium and have a resultant F_r.

* The Electrician, Vol. LXXV., April 16th and May 7th, 1915.

Measure of Single Phase Reaction.

This backward rotating resultant field derived from the current system is evidently a measure of the single phase reaction in the alternator supplying the circuit, and of the double frequency ripple in the flow of power. It appears that in a three-wire circuit this resultant will only disappear if the currents in the three lines are equal, when the voltages are balanced. If, however, a fourth wire is provided to take a resultant out of balance current back to the neutral of the generator, a circuit can be arranged in which the pulsating component of the power disappears, notwithstanding the currents are unbalanced. Thus, a circuit in which the line currents are represented vectorially by OF_1, OF_2, and OF_3, would produce a pure rotating field, but these currents could not flow in a three-wire system, but would require a fourth wire to return to the star point of the alternator the neutral current represented by OF_r. It has been shown by Miles Walker* that the double frequency ripple in the flow of power can be eliminated in an unbalanced three-wire circuit if the voltages are unbalanced.

Four Coil Power Factor Meter in Unbalanced Circuit.

When a four coil power factor meter of the type considered is connected in an unbalanced circuit, the inaccuracy introduced by the backward rotating field will depend upon the phase from which the pressure is obtained, as the angle between this field and the similarly rotating component of the pressure field for a given position of the moving system will be different for each method of connection.

In the case of a four-wire circuit in which the backward rotating field was eliminated it appears that this type of power factor meter would give accurate readings irrespective of the actual degree of unbalance in the three lines, and of the manner in which the pressure coil was connected.

The natural scale of a power factor meter subtends an angle of 120 degrees between the points 0·5 leading and lagging. It sometimes happens that a more contracted scale than this is required for switchboard work, and with a balanced load instrument it is readily possible by increasing the ampere-turns in one of the system of three coils to produce a contracted scale in the neighbourhood of unity. The calculation of the increase of ampere turns necessary for a required contraction is easy when the method of rotating components is used. Considering an instrument with three-pressure coils, if the ampere turns in the coil in the same phase as that of the single coil be n times those of the two other coils, the phase relationships remaining symmetrical, the system is equivalent to a balanced system giving rise to a rotating field of a value $\frac{3}{2}$, on which is superimposed a pulsating field of value $(n-1)$ giving two rotating components of opposite sense, the value of each being $\frac{n-1}{2}$.

The total forward rotating field will therefore be

$$\frac{3}{2} + \frac{n-1}{2} = \frac{n+2}{2}.$$

The backward rotating field is $\frac{n-1}{2}$.

The condition for equilibrium of the moving system is therefore

$$\frac{n-1}{2}\sin(\varphi+\theta) = \frac{n+2}{2}\sin(\varphi-\theta)$$

or

$$\tan\theta = \frac{3}{2n+1}\tan\varphi.$$

Reflection in Telephone Circuits.

By L. C. POCOCK, B.Sc., A.M.I.E.E.

There is probably no part of telephone transmission theory which is so little understood as the phenomenon of reflection in telephone circuits. For some reason this subject is generally treated historically; the supposedly familiar analogous phenomenon in the theory of light and sound is adduced and thence an argument from the existence of wave propagation in long conductors leads to a complex theory of reflected waves in such conductors.

History not the Best Policy.

Now, however natural this course of development may be to the mathematical physicist, it is not the one best suited to the student of telephony, especially if his first serious encounter with the theory of wave motion happens to be in telephone engineering instead of in pure physics. Such a student will probably very soon realise that in a great deal of practical calculation the first step is to replace the wave propagating conductors with distributed constants which are so fruitful of involved formulæ, by equivalent T's or equivalent π's: he will then ask what has become of the reflection effect now that there is no longer any wave propagation in time and space. It is the object of this article to answer such a question.

Let there be two dissimilar lines connected together and let them be represented at a given frequency by equivalent T's such as are shown in Fig. 1, where the Z's are not necessarily pure resistances but may be any kind of impedances.

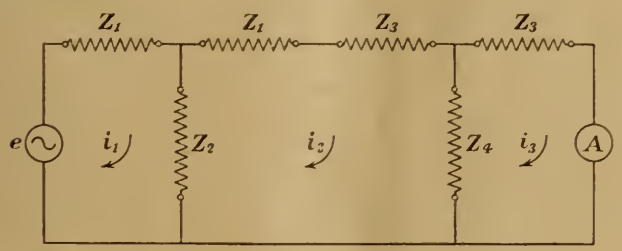

FIG. 1.

Let an E.M.F. e be applied at one end and let the other end be closed through an ammeter: the circuit equations are then as follows:—

$$\left.\begin{aligned}(Z_1+Z_2)\,i_1 \quad -Z_2 i_2 \qquad\qquad &= e\\ -Z_2 i_1+(Z_1+Z_3+Z_2+Z_4)\,i_2-Z_4 i_3 &= 0\\ -Z_4 i_2+(Z_3+Z_4)\,i_3 &= 0\end{aligned}\right\} \quad \ldots\ldots (1)$$

Here we may note that (Z_1+Z_2) is the sending end impedance of the first line with the far end of the same line open, and (Z_3+Z_4) is under the same conditions the sending end impedance of the second line; since these are characteristics of the lines we will replace them by Z' and Z'' respectively.

The equations then take the shorter form:—

$$\left.\begin{aligned}Z' i_1-Z_2 i_2 \qquad\qquad &= e\\ -Z_2 i_1+(Z'+Z'')\,i_2-Z_4 i_3 &= 0\\ -Z_4 i_2+Z'' i_3 &= 0\end{aligned}\right\} \quad \ldots\ldots\ldots\ldots (2)$$

If Δ is the determinant of these equations we find for the current sent i_1, and the current received i_3,

$$\left.\begin{aligned} i_1&=\frac{e}{\Delta}\begin{vmatrix} Z'+Z'' & -Z_4\\ -Z_4 & Z''\end{vmatrix}\\ i_3&=\frac{e}{\Delta}\begin{vmatrix} -Z_2 & Z'+Z''\\ 0 & -Z_4\end{vmatrix}\end{aligned}\right\} \quad \ldots\ldots\ldots (3)$$

Now let the applied voltage and the ammeter change places; we find for the current sent i'_3, and the current received i'_1,

$$\left.\begin{aligned} i'_3&=\frac{e}{\Delta}\begin{vmatrix} Z' & -Z_2\\ -Z_2 & Z'+Z''\end{vmatrix}\\ i'_1&=\frac{e}{\Delta}\begin{vmatrix} -Z_2 & 0\\ Z'+Z'' & -Z_4\end{vmatrix}\end{aligned}\right\} \quad \ldots\ldots\ldots (4)$$

Comparing (3) and (4) we see that the current received is the same in each case but the currents sent differ.

The fact that the currents received are the same in the two cases might be expected from the symmetry of the determinant or the law of reciprocity, which, as applied to current networks states that if a voltage e acting in a branch A of a network produces a current i in another branch B then a voltage e acting in B will produce the same current i in the branch A. A point frequently missed is here made clear, namely that although the transmission allowance of a non-uniform line is generally different in the two directions, yet for a given E.M.F. acting at either end the current received at the other end will always be the same.

The difference between the transmission allowances for the two directions evidently depends on the fact that the current sent is not the same in the two cases and thus we see that the reflection effect makes its appearance as a change in the sending end impedance of the line when the far end is connected to a different line instead of being connected to an indefinitely long line of the same kind. This will be clearer if we consider what is meant by transmission allowance and reflection loss or gain.

The Transmission Allowance.

The transmission allowance for a given piece of line is the length of standard cable (an arbitrarily defined type of cable) in the middle of an infinite standard cable in which the attenuation would be equal to the attenuation in the given piece of line if the given piece of line were placed in the middle of an infinite line of the same kind as itself. The allowance depends therefore upon the attenuation it produces when it is so connected that there is no reflection effect at the ends.

Confining ourselves to line No. 1 represented by the impedances Z_1 and Z_2 the actual attenuation is found in accordance with the above definition by putting the section considered between two long lengths of line of the same kind, and since the physical construction of the line is of no importance so long as the network representing it has the same input impedance at the frequency considered, we may evidently substitute for the long line a simple impedance Z_0 equal to the sending end impedance.

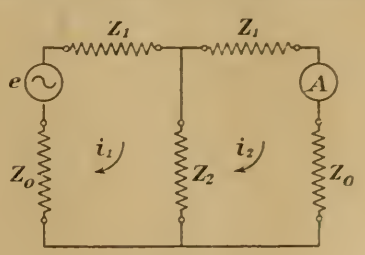

FIG. 2.

The equations are:—

$$\left.\begin{aligned} i_1\,(Z_0+Z_1+Z_2)-i_2 Z_2 &= e\\ -i_1 Z_2+i_2\,(Z_0+Z_1+Z_2) &= 0\end{aligned}\right\} \quad \ldots\ldots\ldots (5)$$

so that the attenuation

$$\frac{i_2}{i_1}=\frac{Z_2}{Z_0+Z_1+Z_2}=a$$

but if the short line is connected at its far end to some other impedance Z we find

$$\frac{i'_2}{i'_1}=\frac{Z_2}{Z+Z_1+Z_2}=a'$$

so that if r is the attenuation equivalent to the reflection effect between the line of characteristic impedance Z_0 and the line of actual impedance Z

$$r\,\frac{i_2}{i_1}=\frac{i'_2}{i'_1} \quad \text{or} \quad r=\frac{a'}{a}=\frac{Z_0+Z_1+Z_2}{Z+Z_1+Z_2}$$

whence we see that if Z_0 is greater than Z the attenuation is greater than unity so the reflection effect is a gain and if Z_0 is less than Z there may be a loss.

We also see that if the length of line for which we have substituted a T is made very long, Z_1+Z_2 approaches the limiting value Z_0; thus the typical reflection effect at the junction of two lines having impedances Z_0 and Z is $\frac{2Z_0}{Z+Z_0}$ in the direction Z_0 to Z. The reflection attenuation in the reverse direction will be different for evidently it will be $\frac{2Z}{Z+Z_0}$.

If the impedances Z and Z_0 have the same angle, $\frac{2Z_0}{Z+Z_0}$ is a real fraction, but if they have not the same angle r is a complex quantity and must for given values of $|Z|$ and $|Z_0|$ be greater than $\left|\frac{2Z}{Z+Z_0}\right|$. Hence, any difference of angle between Z and Z_0 leads to a reflection gain as compared with the reflection attenuation expressed by the modulus of r.

Separation of Reflection Effect.

Thus it is seen that the reflection effect can be separated into two parts, one depending on the ratio of the moduli of the impedances connected together is a loss in one direction and an unequal gain in the other. The other part is always a gain and depends upon the difference of phase angle between the impedances as well as the ratio of the moduli.

Secondly it has been shown that reflection has the effect of altering the sending end impedance from what it would be if the given line were infinitely long, to a value determined by the terminal impedance.

A Story of Trade.

In a recent address to the Students' Section of the Institution of Electrical Engineers Mr. J. S. Highfield remarked that true engineers always remain students because the science on which their business rests is always advancing and because all engineering work is "team work," involving a knowledge of human nature. The present time is a difficult one for everyone, and not least for students. Anxiety will remain until trade improves. The reasons for the present trade depression are many, and the subject is of vital importance to engineers. Engineering schools should pay more attention to principles of trade and commerce.

Electrical Engineering Development.

Mr. Highfield traced the development in electrical engineering from the days when electricity was studied only by a few men gifted with the love of natural science. He recalled the results of Faraday's discovery in 1832, which only led to the first useful dynamo about 1870. Modern engineering took its birth from the invention of the steam engine, but the methods pursued by early investigators were necessarily different from those demanded by the complex conditions prevailing to-day.

Trade has always been largely a matter of adventure. In early days merchants were often captains and owners of small vessels, and risked all—vessel, cargo, and life. The advances made by the engineer were rendered possible by the efforts of the successful trader who found the money, the surplus of food and goods that forms the foundation of all progress. There are two broad classes of men, the traders, the masters who bear the risks, and the salaried workers who may share the responsibility with the owners but do not run the same risks. This vast difference is not sufficiently realised. It would seem that training colleges are somewhat apt to turn out men inclined towards accepting a salary, rather than to risk all in initiating new ventures. There are countries and parts of the Empire with ample space for new adventure. One would like to see them tested by a proper colonising venture, consisting of picked men and women skilled in appropriate trades. The conception is not new; it was used centuries ago by the Greeks. The main difficulty in such cases is to find an efficient leader. An engineer's training fits him for carrying out a multiplicity of jobs, and he can render useful service in such ventures.

The Indu tries of Cornwall.

The war had damaged all business, including engineering. But there were other industries in a much worse condition. As an instance Mr. Highfield mentioned the industries of Cornwall. The mines of Cornwall date back to very early times. But even to-day there is a great element of chance in opening up new workings in tin and other metals, and the variations in complexity of different lodes are remarkable. The Cornish mines have sent skilled workers to all parts of the world. The china clay industry is another one that has fallen on bad times. This is an interesting process, of relatively recent growth. The clay is decomposed granite, originally used only for pottery, but in 150 years has grown to a business greater than the tin mining industry. The rock contains about 20 per cent. of clay substance varying in colour from pure white to yellow; besides its use for pottery the clay is used for filling paper and other fibrous and cellular materials. It is obtained in modern plant by hydraulic mining with pressure jets, and in all the processes there are fine opportunities for resource and ingenuity. All the traders are relatively poor, but the skill of the workers is great, and Cornwall and the Camborne School of Mines have sent skilled miners to all parts of the world. On these primary trades depend coal miners, rope and sail makers, shipbuilders, carriers, manufacturers of plant, and finally the electric power company. Now, owing to the failure of the tin mining, then of the export trade in china clay, all are in want. Coal is not wanted, electric power output is reduced to a point where the company cannot meet expenses, and all subsidiary trades suffer. The failure in Cornwall is not due to strikes or demands for unpayable wages. The source of their wages is so clear that the men are fully seized with knowledge of economics. They are willing to work for any living wage, but there is no one to pay it. The position is a grievous one and there is no clear remedy. Until the American demand increases there is no prospect of revival in china clay.

Adventure and Risk.

Mr. Highfield mentioned these circumstances as an illustration of the risks underlying trade, and the misfortune that may occur, in spite of honest endeavour. Generally speaking, the man who made safe investments, primarily to provide for old age, did not help trade much. The essence of trading is adventure involving risk, carried either by the man who trades with his own money or by investors in ordinary shares; When ordinary shares were in demand, then it could be said that trade was reviving.

In concluding his address Mr. Highfield suggested that a study of the history of trade was full of interest. History was taught too much in terms of the doings of kings, their ministers, and the law makers, rather than of the traders in whose interests many of the laws were made and many wars fought. The record of Simon of Montfort, the Wars of the Roses, and the laws of Henry VII and the Stuart times should be examined in the light of trade. The histories of City companies often provided interesting and even exciting reading. The lives of such men as Thomas Gresham and Cecil Rhodes afforded examples in adventure and statesmanship. It was for the young men to remain students and to add to the greatness of the Empire by facing fortune, bearing the risks, and winning the rewards, as in days of long ago.

The Anti-Dazzle Problem.

In a lecture, last Thursday, before the Optical Society on the problem of glare from motor head-lights, Mr. J. W. T. Walsh, of the National Physical Laboratory, said the number of devices to give the lamp beam the required distribution to eliminate glare—including those which were on the market—was very great. Some 2 000 had been produced over five years ago, but the problem might still be regarded as awaiting solution. The difficulty lay in the fact that, while a safe driving light required a beam of at least 3 000 c.p., it was necessary, in order to avoid glare to drivers of oncoming traffic, to reduce this to about 500 c.p. There appeared to be no really satisfactory method of escape from this position of mutually antagonistic requirements. In the United States the problem had been dealt with by confining the main part of the beam to the region below the horizontal. Mr. Walsh emphasised the desirability of uniformity of anti-dazzle legislation throughout the world, and mentioned that the International Commission on Illumination had appointed a special commission to secure this object.

Recent Improvements in Railway Electric Traction Equipment.*

By ROGER T. SMITH.

The author discusses the relative financial advantages in this country of steam and hydraulic stations and shows that generally for agricultural reasons the former will continue to be used. He gives for the first time details of a new machine for converting alternating to direct current and then brings up to date the figures for the cost of haulage by electricity and steam which he set out in his Presidential Address to the Institution of Electrical Engineers. Finally he reiterates his opinion that railway companies and manufacturers should work in the closest conjunction for the production of electric traction equipment.

Uniformity of electrical equipment on the railways of a country is of more importance than a relatively small saving to-day upon one system which might be turned by progress into an equal loss to-morrow.

The recommendations in the final Report of the Ministry of Transport Advisory Committee on the Electrification of Railways urged uniformity, and the author claims that the advantages to be derived from following these recommendations will in the long run lead to the least capital expenditure for a given group of railways and result in the least working expenses to each group. The only exception to the recommendations is the Brighton Railway, and time alone can show if the inconvenience of its isolation from through running is as free from serious objection and its economics are as sound as they appeared to the Committee to be.

Economies in Railway Electrical Equipment.

Hydro-electric generating stations will in general compare unfavourably with steam turbine stations in Great Britain. For a steam-power station with a maximum load of 100 000 kW the cost exclusive of the site is of the order of £18 per kW of maximum load, and may be less. Hydro-electric plant worked at 50 per cent. load factor requires two-thirds of an acre of water 1 ft. thick falling 1 ft. for each kW of plant installed. £20 per acre for agricultural land is an often quoted figure in this country, so that it is evident that if a steam station costs less than £18 per kW the cost in an agricultural district of the land alone required for water storage, without any hydraulic works or machinery, becomes prohibitive unless the fall of water is very considerable.

Statistics of 463 generating stations consuming coal or coke show that during the year ending March 31, 1921, the highest thermal efficiency of any station was 17·75 per cent., and the lowest coal consumption per kWh generated was 1·70 lb. The average consumption of coal per kWh for these 463 stations was 3·32 lb., the kWh generated being approximately 5 000 000 000. Electrical engineers and turbine makers together have been able to improve the thermal efficiency of large steam turbo-generators with outputs of the order of 15 000 kW to 20 000 kW until to-day station efficiencies are being obtained of 20 per cent. in actual practice, and in the newest stations an efficiency of 24 per cent. is confidently anticipated. Under test conditions thermal efficiencies of 25 per cent. have been obtained from individual turbo-generators since 1913. The thermal efficiency of a steam locomotive is believed to range from 6 per cent. downwards during the time the locomotive is actually in traffic.

Power Station Economies.

The long sequence of economies in power stations containing large units of power each of at least 15 000 kW output, has resulted in generating the kWh for an expenditure in coal of not more than 1½ lb., the coal having a calorific value of not less than 11 000 B.Th.U. and costing to-day about 8s. per ton at the pit.

Two tables, one showing typical capital and working costs for generating stations of various sizes and the other showing the cost of three-phase transmission systems for carrying the electricity to sub-stations where it can be transformed or converted for distribution are given in paper. These tables were taken from a paper read by Mr. Highfield in 1919, and have been brought up to date. After analysing these tables the author proceeded to consider whether there was any prospect of reducing the cost of transmission either by the employment of the Thury system or by the use of the "Transverter," designed by Mr. W. E. Highfield and Mr. J. E. Calverley.

The "Transverter."

The latter machine is for producing direct current from alternating current and consists essentially of a static transformer and of a fixed commutator with revolving brush gear driven by a small motor running in synchronism with the alternating current supply to the primary windings of the transformer. Secondary windings on the transformer connect to the commutator, which converts the alternating current to direct current. Several groups of secondary windings may be placed on the transformer and by connecting them to commutators connected electrically in series, high pressure direct current is produced. Each commutator in the first made machine deals with a pressure of the order of 12 500 V, so that the eight commutators provided give 100 000 V. Figures were quoted showing a saving of some 50 per cent. in a sub-station plant equipped with transverters, as against rotary converter equipment.

The inventors have allowed the transverter to be publicly mentioned for the first time in this paper, because, should the method of conversion and transmission be proved to be a commercial success, the apparatus becomes a matter of outstanding economic importance to railway electrification, as well as for the inter-connection of generating stations, and for transmission generally.

Cost of Electric Haulage of Trains.

In the author's address to the Institution of Electrical Engineers in 1919, an attempt was made to compare the costs of electric and of steam working on main line railways. The method of comparison was to analyse the locomotive working costs of one large railway which for steam working showed fair average annual costs per steam locomotive, and to couple those costs with the train mile, which is the most convenient revenue earning unit. In the anlaysis the locomotive costs were £1 240 per annum for a passenger locomotive in 1913, inclusive of 5 per cent. interest on the cost of the locomotive, and for a goods locomotive, £1 020. These costs were averaged over the total number of locomotives possessed by the railway, and not only those available at any one time for service. The locomotive costs—superintendence, running wages, fuel, water, lubricants and other stores, repairs and renewals of locomotives, including depreciation and interest at 5 per cent. on the first cost of the locomotive—per average train mile hauled during the year by the respective types of locomotives were 11d. per passenger train mile, and 2s. 0½d. per goods train mile. In 1919 the locomotive costs per passenger train mile were raised to 2s., and per goods train mile to 4s. 8d. On the assumptions made it was shown that if electric locomotives were substituted for steam locomotives, electricity costing ½d per kWh and the electric locomotive costing (as it did then) 2½ times the cost of the steam locomotive, a first charge of 5 per cent. on the cost of the electrical equipment of the line including locomotives would only allow a passenger train of the average weight of 175 tons to be hauled electrically, but would allow a goods train of 1 000 tons to be hauled electrically.

Working Costs and Revenue.

Careful consideration points to the most satisfactory unit of working costs and of revenue to be the train mile per engine hour. Both quantities can be obtained with a fair degree of accuracy. In 1920 the train miles per engine hour for all steam locomotives in Great Britain, including all shunting hours and miles as taken from the Blue Book, were: coaching 9·64, freight 3·18. The annual locomotive costs of all the engines in Great Britain—these costs comprising superintendence, locomotive running wages, coal and water lubricants and other small stores, and maintenance and renewal of locomotives—amounted in 1920 to £3 088 per engine, or per engine hour to 22s. 8d.

An analysis of the same figures arranged for main line and branch line electric locomotives moving both passenger and freight trains, gives the cost per engine hour as 25s., but this assumes that the engine hour of the steam and of the electric locomotive represents the same work done, which is not the case.

* Abstract of a Paper read before the Institute of Transport.

Comparative Costs of Steam and Electric Working.

The comparative costs as between steam and electric working where a steam railway is converted consist therefore in the capital and maintenance charges on the electrical equipment of the track and the locomotive working costs, all capital charges on the generating station and on the sub-stations (if any) being included in the cost of electricity. In a particular case in Great Britain, using round figures, the annual working cost of the steam locomotives for working 400 miles of busy single main track line for passenger and goods service with extensive sidings is estimated to be £3 200 per annum for steam locomotives and £5 700 per annum for electric locomotives with electricity delivered to the track at 0·7d. per kWh. This sum of £5 700 includes also the maintenance of the track equipment and interest at 6 per cent. on its first cost. But whereas 200 steam locomotives are required to work the existing service, only 100 electric locomotives are required to work the same service, so that for the same haulage the annual cost of electric working per existing steam locomotive is £2 850, or a saving of £350 per annum for each steam locomotive replaced.

If, however, instead of electricity being delivered to the track at 0·7d. per kWh as above, it is delivered from a generating station at 0·4d. per kWh, so that the losses, capital, and maintenance charges making up the cost of transmission are not included, nor the working capital and maintenance charges on the sub-stations, the annual working costs per electric locomotive become £4 800 or £2 400 per steam locomotive replaced. This is a saving of £800 per annum for steam locomotives replaced, out of which saving has to come an unknown amount for the annual cost of transmission and of sub-stations. The average number of steam locomotives in Great Britain per mile of single track on December 31, 1920, as taken from the Ministry of Transport Blue Book, was 0·48.

Capital Charges.

For a fairly busy line where goods traffic exceeds passenger traffic, requiring a steam locomotive to work the traffic for every two miles of single track, replaced out of revenue by an electric locomotive for every four miles of single track, the capital charges which must be met out of savings in locomotive expenses will be :—

	Single track.
First cost of electric equipment of the track consisting of 70 lb. per yard conductor rail, laid, jointed and protected against 1 500 V d.c. with bonds for both contact and for running rails, cost per mile	£2 000
First cost of sub-stations and their equipment each giving 3 000 kW at rated output and 6 000 kW on overload at 1 500 V spaced 10 miles apart, cost per mile	£2 000
Cost of transmission	Unknown
Cost per mile	£4 000

The annual saving per steam locomotive displaced is £350 per annum on the assumption that electricity is delivered to the track at 0·7d. per kWh, saving per mile, £175 ; or a saving of £800 per locomotive per annum on the assumption that electricity is delivered from the generating station at 0·4d. per kWh, saving per mile, £400.

Electrical Savings.

Where it is assumed that electricity is delivered at 0·7d. per kWh to the contact rail, including the sub-station working costs, maintenance and interest, the saving is £175 on £2 000, representing 8¾ per cent. profit on the capital over and above interest at 6 per cent. on that capital, this interest having already been included in the annual working costs. This covers the case of a railway supplying itself with electricity from its own generating station close to the track with only transmission along the track to the sub-station. Where electricity is delivered at 0·4d. per kWh from a generating station, the saving of £400 per mile of single track makes no allowance for capital charges or working costs for the transmission and sub-stations. These may be taken as follows :—

	Cost per mile of single track.
Losses in transmission and conversion, reckoned at 20 per cent.	£70
Sub-station staff and maintenance	100
Interest at 6 per cent. on cost of sub-station	120
	£290

This leaves a balance of £110 per mile of single track to pay interest and maintenance charges on the transmission and provide a profit on a capital of £4 000 additional to the 6 per cent. already charged.

Manufacture of Electric Locomotives.

A railway company of necessity maintains its own steam locomotives. The great railway companies have elected also to construct these locomotives, such work representing considerably less than half of the work of maintenance, repair and renewal. Commercial locomotive builders in this country, outside the railways have in consequence a small home market, the bulk of their business being abroad. It is generally held that in the manufacture of machinery both a home and a foreign market are necessary for the best progress and for the full development of ideas. There is no doubt that by their policy the railways have saved a certain amount of money on the construction of new locomotives and that they build machines which, designed by engineers who have to maintain them, have a long useful life.

It is, however, a matter for speculation whether, if the railways had encouraged commercial locomotive building by buying from outside, this country might not have taken the same place in the world's market in locomotive building as it has in shipbuilding and in marine engineering. It is possible that in hauling the materials required for such a world trade the railways might have gained in revenue sums compared with which the saving in the first cost of locomotives is insignificant.

The Part the Manufacturer should Play.

It does, however, seem worth while, on the eve of a demand for electric locomotives for the railways, to consider whether an organisation and workships designed for efficient and successful maintenance are the best for constructing electric locomotives, which require electrical and mechanical research of the highest order, and the employment of every advance in electrical and engineering knowledge not only in locomotive building, but in several branches of electrical engineering. Advances in the design of electrical machinery in this country are almost entirely due to electrical manufacturers and to workers in pure science and the manufacturers have spent millions of pounds in experiment and research. Railway electrical engineers in this country have not been in a position to contribute anything of importance to the research and experiment needed in the development of the electric locomotive, nor will they be able to do so if electric locomotives are manufactured in workshops organised and staffed for maintenance only. It has not been the custom for our railways to set aside regular sums for general research, although some of our locomotive departments have spent and are spending considerable sums on individual researches. The organisation for research in the electrical industry apart from railways is on a sound basis, and is more than adequate for electric locomotive building if the railways choose to use it.

It is therefore a question whether it would not pay the railways of this country at least to give a fair trial to the policy of helping to build up the manufacture of the electric locomotive in Great Britain by commercial firms, who, with an important home market as well as a foreign market, would have a chance of creating a world trade.

Electricity Supply Progress in America.

According to Statistics Compiled by the "Electrical World," 72 electric light and power, and nine electric railway companies of the United States and Canada had an output exceeding 100 000 000 units in 1921. Five United States companies supplied over one thousand million units, compared with seven American and two Canadian companies in 1920. The Commonwealth Edison Co. of Chicago, which added 40 000 new lighting consumers in 1921, now heads the list with an output of nearly two thousand million units, and is followed by the Niagara Falls Power Co. (mainly an industrial power concern, which was first in 1920), the Pacific Gas and Electric Co., the New York Edison and United Electric Light and Power Companies (grouped as one), and the Southern California Edison Co. The figures show clearly that the country has been suffering from trade depression, for companies, such as the Niagara Falls, Detroit and Montana undertakings, which supply industrial and mining areas appear to have suffered most.

The total output of the 72 light and power companies was 31 603 021 872 units, of which 3 225 939 413 units were distributed by Canadian companies. The figures of the American companies represent 65 per cent. of the total output of all public electric generating and distributing companies during 1921. The larger supply undertakings are not confined to any part of the country, but the Pacific and Middle Atlantic States have each two billion unit companies.

Short-wave Directional Wireless Telegraphy.*

By C. S. FRANKLIN.

In this paper it is proposed to give some results of investigations made with reflectors and wave-lengths below 20 metres. The investigation was commenced by Mr. Marconi in Italy in 1916.

The waves used were 2 metres and 3 metres. The only interference experienced with such waves is from motor boats and motor cars. These machines apparently emit waves from near zero up to about 40 metres in length. At Mr. Marconi's suggestion a coupled-circuit spark transmitter was developed, the primary having an air condenser and spark in compressed air. By this means a moderate amount of energy was obtained, and the small spark-gap in compressed air proved to have very low resistance. The decrement of the waves emitted was judged to be of the order of 0·03.

The receiver used was a carefully picked crystal, while the reflectors employed were made of a number of strips or wires tuned to the wave, arranged on a cylindrical parabola with the aerial at the focus. The transmitting system was arranged so that it could be revolved and the effects studied at the receiver.

Italian and British Experiments.

These Italian experiments showed that good directional working could be obtained with reflectors properly proportioned with respect to the wave-length. The attenuation over sea for the wave-length used was found to be very high, and with the apparatus available the maximum range obtained was 6 miles.

The experiments were continued at Carnarvon in 1917. With an improved compressed-air spark transmitter, a 3-metre wave and a reflector having an aperture of 2 wave-lengths, and a height of 1·5 wave-lengths, a range of over 20 miles was obtained to a receiver without a receiving reflector. The experiments at Carnarvon brought into prominence a very rapid increase in the strength of the electric field with height above the ground. The rate of increase appears to be a function of the height divided by wave-length, and while not very noticeable with waves of several hundred metres, is very marked with waves of a few metres, length.

In 1919 experiments were commenced at Carnarvon with valve transmitters, with the idea of producing a directional telephone system. Mr. R. H. White and Mr. E. Green, and, later, Mr. A. W. Hall, assisted the author in this work. A wave of 15 metres was selected, which while well within the capacity of the power valves available, allowed a simple reflector to be used without too large a structure. After some trials a single valve transmitter was arrived at taking about 200 W with a 15-metre wave, and giving 1 A in the centre of a half-wave aerial. A heterodyne receiver with supertonic beat-note was employed.

After gaining some experience, and solving many small practical difficulties, very strong speech was obtained at Holyhead, 20 miles away. The strength was such that shadows produced by small hills and buildings were hardly noticeable, unless the stations were close behind them.

In June, 1920, during this test, speech was received right into Kingstown Harbour, 70 nautical miles from Carnarvon, and the point was proved that there was no rapid diminution of strength after passing the horizon line from Carnarvon.

Range of Short Wave Reflector System.

As a result of these experiments it was decided to test the range of a short-wave reflector system wholly over land. A site was chosen at Hendon, and a reflector and transmitter for 15-metre waves erected with the reflector pointing towards Birmingham. Tests were commenced in February, 1921, from Hendon to a portable receiver on a motor car. Very good speech was received up to 66 miles, and fair speech in the neighbourhood of Birmingham. A reflector station was then erected at Frankley near Birmingham, 97 miles from Hendon, and tests were started there in August, 1921.

Transmitting Arrangements.

The transmitter consists of two medium-size power valves working in parallel. The power to the valves is usually 700 W (4 000 V, 175 mA). The aerial is rather longer than half a wave-length, and has a radiation resistance of the order of 90 O. The efficiency, input to valves to aerial power, is between 50 and 60 per cent., and about 300 W are actually radiated. With the reflectors up at both ends speech is strong, and of very good quality. It is usually strong enough to be just audible with a $\frac{1}{4}$ to $\frac{1}{2}$ O shunt across a 60 O telephone.

With both reflectors down the speech is usually only just audible with no shunt. Average measurements indicate that the energy received when both reflectors are up is about 200 times the energy received when not using the reflectors. Thus to get the same strength without reflectors as with them a 140 kW valve transmitter of the same efficiency would be required. Local measurements of the polar curves taken round the station show that the electric field in front of the station is increased approximately four times by the use of the reflector, and that the same order of increase is obtained during reception; the increase of energy received due to the use of the two reflectors should therefore be $4^2 \times 4^2 = 256$ times.

Experiments made with revolving reflectors, where it is comparatively easy to make measurements at any distance, prove that the polar curve is practically constant at all ranges.

Production of Short Waves.

The production of waves of the order of about 12 metres and upwards is quite practicable up to several kilowatts by large power valves, and it is also practicable to operate valves in parallel. With such high frequencies very large currents pass into the grid and anode; the seals through the glass must, therefore, be large. The production of a reliable transmitting valve entailed a large amount of work, and the great dissimilarity of results from apparently similar valves was very puzzling for some time. In a new batch of valves the efficiency at 15 metre wave would vary from about 60 per cent. down to 5 per cent., and if any attempt was made to push up the power on a bad valve the glass would promptly melt at some spot. The cause of the trouble has been found to be due to losses in the deposits on the glass, owing to high-frequency currents induced. Such deposits are always produced in valves during exhaustion, and vary considerably.

If a number of valves are laid successively between the plates of a small air condenser in a very high-frequency field of the order of 20 000 000 per sec. (without making any connections to the valves), the results are quite remarkable. Some produce no appreciable effect, while others at once put a big lead on the circuit, and if 200 W of high-frequency energy are available, the glass gets hot and will quickly melt at some spot. One of my assistants, Mr. E. Green, made the useful discovery that if the electric field in the neighbourhood of the valve was constrained by means of a shield, so that it was at right angles to the deposit on the glass, then this loss disappeared, and a formerly bad valve would give nearly the same efficiency as a good one. It is now therefore possible to use what are practically standard valves, and their life appears to be about the same as for lower frequencies.

Reception on Transmitting Aerial.

During the continuous-wave tests at Carnarvon it was found that reception was quite possible on the transmitting aerial while the transmitter was operating. This has been used successfully for duplexing between Hendon and Birmingham, and eliminates all switching.

The heterodyne may be either the transmitter, or an independent small heterodyne in the receiver. Both the transmission and the reception utilize the same aerial and reflector, and the transmitter is left going and can be operated while receiving.

There is no reduction in strength while the transmitter is on, but a practical trouble has appeared. Owing to the comparatively large power, strong currents are induced in all conducting structures and circuits close to the reflector and transmitter, such as the supporting towers and buildings, and every variable contact produces a noise. The elimination of all variable contacts in the neighbourhood of the transmitter has proved a work of some magnitude.

Advantages of Reflec ors.

Reflectors besides giving directional working, and economizing power, are showing another unexpected advantage, which is probably common to all sharply directional systems. It has been noted that practically no distortion of speech

* Abstract of a Paper read before the Wireless Section of the Institution of Electrical Engineers.

occurs, such as is sometimes found with non-directional transmitters and receivers.

Although the results between Hendon and Birmingham constitute a record for telephony for ratio of range to wave-length—for such results were believed to be impossible two years ago—they are only a first attempt and do not represent the best that can now be done after the experience gained. Birmingham, it is interesting to note, is 10 400 wave-lengths from Hendon.

It has thus been demonstrated that wave-lengths of the order of 20 metres are quite capable of providing point-to-point directional commercial service over very considerable ranges. Such services will be comparatively secret as compared with the usual non-directional type of transmission.

The directional effect obtained with reflectors which are large compared with the wave-length, is so good that it was suggested that it would prove very useful for position finding for ships near dangerous points.

An experimental revolving reflector was erected on Inchkeith, and tests were made to s.s. " Pharos," the lighthouse tender of the Northern Lights Commissioners during the autumn of 1920. With a 4-metre wave, spark transmitter, a reflector of 8 metres' aperture, and a single valve receiver on the ship, a working range of 7 nautical miles was obtained. The reflector made a complete revolution once every two minutes, and a distinctive signal was sent every half-point of the compass. It was found that this enabled the bearing of the transmitter to be determined within $\frac{1}{4}$ point of the compass, or within 2·8 degrees.

DISCUSSION.

The Institution lecture theatre was crowded and a very appreciative audience had the pleasure of hearing a most interesting paper, an abstract of which we give above, delivered in an unusually short space of time and of seeing some very successful demonstrations.

A tiny transmitter with reflector, was installed on one side of the lecture table, and was shown clearly to have its radiation confined to a beam directed upon the receiver on the other side of the lecture table. The radiation was shown to be absorbed by the body and by a suitably tuned coil of wire. The transmitter with its reflector were rotated several times while signals were being sent. As the beam traversed the receiver the signals were picked up and reproduced in a loudspeaker.

Many Compliments.

The discussion was largely of a complimentary nature. Mr. G. Marconi recalled his early experiments in which he showed Sir William Preece the successful transmission of short waves over $1\frac{3}{4}$ miles where a range of only $\frac{1}{2}$ mile was possible without reflectors. This was 26 years ago, and almost immediately afterwards the progress of the elevated wire system was so rapid that it took all attention.

Major R. C. Trench thought the author's claim for economy was not sustained by the power of 700 W required to telephone 97 miles. He thought the weight of the reflector made the system inapplicable to work in the field, but as the author had pointed out that the strength of the electric field increased rapidly with height above the ground the system would have some application as regards air craft.

Mr. J. E. Taylor was not new to the subject. He had advocated research on similar lines during the early days of the War on account of the need for secrecy. He looked forward to better results with even shorter waves than those employed by the author and thought that by some such reflector system wireless telegraphy would before long take the place of land lines.

Major H. G. T. Lefroy had worked on the subject in 1913, using a Hertzian oscillator for working to airships.

Useful for Marine Work.

Mr. A. Grey read a letter from the consulting engineers to the " Northern Light," expressing the opinion that for giving bearings to ships at sea and as fog signals this system promised to revolutionise present practice.

Mr. R. Carpenter enquired why radiation was not restricted in the vertical plane. He suggested that the axis of the small transmitting aerial might be made horizontal instead of vertical and that the reflector made in the shape of a parabeloid.

Prof. G. W. O. Howe referred to the enormous range of wave-lengths now covered by wireless, namely 16 octaves, from 1 metre to 30 000 metres. This was greater than the range of either the " eye " or the ear."' ' As regards the increase of field strength above the surface of the earth, he enquired whether experiments had been made to determine the nature of the field near the earth surface. He thought that the wave front would be found to be sloped and that the maximum effect would be obtained from an aerial with a corresponding slope. He did not understand why the distortion of telephony should be less when a directional system was employed.

Replying to the discussion Mr. Franklin said that attempts had been made to compare the attenuation of short-wave signals over land and sea, but the results had been inconsistent. He had in view the question of the best wave-lengths to employ and had a new valve which was suitable for wave-lengths of 20 or 30 cm. He found standard power valves satisfactory for 12 metres and had had special valves made for 2 metres. The experimental work mentioned by Mr. Carpenter had already been done. As regards the slope of the wave-front, he found this about 20 deg. with the vertical, but he did not consider that the weak signals at the earth's surface had only to do with that. He agreed that the lack of distortion was probably due to the use of short wave-lengths rather than to the directive transmission.

Recent B.E.S.A. Publications.

Among recent publications of the British Engineers' Standards Association is B.S.S. 108—1922, which is put forward as the first list of British Standard Graphical Symbols for use in Electrotechnics, and is the result of cordial co-operation between Government Departments, I.E.E. Technical Societies, Industrial Organisations and Experts interested in the subject.

While it is realised that the list is admittedly incomplete, it is felt that it will meet a long-felt need, in view of the fact that at the present time Public Departments, Manufacturers' Associations and engineers employ their own individual lists of symbols leading to obvious confusion, and an unnecessary duplication of work. The symbols should be of particular assistance to export work. A large number of them will be found in agreement with symbols used in other countries.

All publications of the B.E.S.A. being subject to periodical revision, provision has been made, in numbering the symbols, for many additions.

Two Points for Notice.

Two points especially may be noticed. In section 7, " Telegraphs and Telephones," the scheme of symbols and conventions adopted by the Post Office has been largely utilised. The symbols in section 8, Radio Communication, were prepared by a joint committee of the Post Office, Admiralty, War Office, Royal Air Force and Marconi's Wireless Telegraph and Telephone Company, Ltd. The main object before the Association has been to endeavour to draw up a list acceptable to every branch of the industry, and it is urged that every engineer should assist the work of the Association by using this list.

Annealed Copper Wires.

Another publication is Specification No. 128—1922. This specification, which gives the Dimensions and Resistances of Annealed Copper Wires, has been issued to meet the needs of the users of copper wire for winding electrical machinery and apparatus, and refers only to bare annealed high conductivity copper wire.

The values of the resistance given have been calculated from the value for the resistivity of copper laid down by the I.E.C. The resistivity of commercial copper at the present time is variable, and therefore a tolerance on the standard values of resistance of $1\frac{1}{2}$ per cent. has been adopted for use until such time as conditions in regard to copper improve.

Following the general trend of modern practice, the sizes are designated by the diameter expressed in decimals of an inch, and should be styled " British Standard Sizes " (B.S.S.) of wire.

The importance of aiming at the use of a small number of sizes by the designers of plant lies in the need for users to carry stocks of all sizes in which they are interested for rewinding purposes; therefore it is particularly important, especially for colonial and foreign customers, and for Government use abroad, that the number of such sizes be restricted as much as possible.

With a view to encouraging reduction in the number of sizes commonly used, the twenty-nine sizes which constitute the even numbers of the S.W.G. are classed as *primary standard* sizes. The remaining twenty-eight are *secondary standard* sizes, and use of the third class or *exceptional standard* sizes should, it is urged, be restricted to the utmost.

Copies of both these publications may be obtained from the offices of the Association, 28, Victoria-street, London, S.W.1.

Sir Frederick Orr-Lewis, of Montreal, Canada, founder and president of the Canadian Vickers, who died last November, has left property in this country of the value of £18 342.

Correspondence.

CHAINS OF MAGNETICALLY-COUPLED CIRCUITS.

To the Editor of THE ELECTRICIAN.

SIR,—With reference to Dr. Bellini's article in THE ELECTRICIAN for 12th instant, may I be allowed to point out that the determinantal expression for n magnetically-coupled circuits may be written in the equivalent form :—

$$\begin{vmatrix} \frac{1}{C_1}-L_1p^2 & -M^2_{12}p^4 & 0 & . & 0 \\ -1 & \frac{1}{C_2}-L_2p^2 & -M^2_{23}p^4 & . & 0 \\ 0 & -1 & \frac{1}{C_3}-L_3p^2 & . & 0 \\ . & . & . & . & -M^2_{n-1,n}p^4 \\ 0 & 0 & 0 & -1 & \frac{1}{C_n}-L_np^2 \end{vmatrix} = 0$$

which is a *continuant*, and as such can be evaluated from inspection—*i.e.*, without actually multiplying out. For, putting P_1, P_2, P_3, etc., for the quantities in the principal diagonal, and Q_1, Q_2, Q_3, etc., for the quantities in the neighbouring bordering diagonal, we may write the expression in the special notation—

$$\Delta \equiv (P_1, -Q^2_1, P_2, -Q^2_2, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . P_n)$$

and this may be developed—

$$\Delta \equiv P_1 (P_2, -Q^2_2, \quad . \quad . \quad . P_n) - Q^2_1 (P_3, -Q^2_3, \quad . \quad . \quad . \quad . P_n)$$

and so on. Dr. H. W. Malcolm has used determinants of the above type very extensively in his "Theory of the Submarine Telegraph and Telephone Cable" (Benn Brothers, Ltd.), and the present writer gave, in the "P.O. Electrical Engineers' Journal" for April last a rule based on the properties of continuants, for writing down from inspection the expansion of determinants of this type. Following out the suggestion made by Mr. L. C. Pocock in THE ELECTRICIAN of August 6, 1920, the present writer also dealt with the case of three magnetically-coupled circuits in "Electricity" of September 9, 1921, and obtained the values of the frequencies with and without a condenser in the intermediate circuit.—I am, etc.,

H. P. FEW.

Engineer-in-Chief's Office,
G.P.O., London.

HIGH VOLTAGE SWITCHGEAR DESIGN.

To the Editor of THE ELECTRICIAN.

SIR,—We have read with very great interest the article appearing in your issue of the 5th inst. on the above subject by Mr. W. A. Coates, and your editorial comments on same, and we are pleased to note that due recognition has been given to the experience of Continental manufacturers.

There is one point, however, in the article referring to insulator dimensions which we think calls for some comment and explanation. The dimensions given in Table I. are approximately the dimensions of insulators used on the Continent, but it is not said positively whether the lengths in the table are to be understood to be the spark-over distance of the complete insulator with fittings or of the bare porcelain.

The essential point for the customer is the test voltage up to break-down voltage in air. The new Swiss prescription for testing high voltage insulators demands, when test voltage $=E_t$ and working voltage $=E_w$:—

$$E_t = 1{\cdot}8 \times E_w + 20\,000 \text{ V.}$$

This results in a higher test voltage for the voltages most frequently used in England than that which English or American firms have offered up to the present. The resulting test voltage is also higher than specified either in English or American prescriptions. We may say that the insulators used by us come up to the new prescription as given above, and it may be of interest to you that it is exactly on the score of guaranteed test voltage that American porcelain manufacturers encounter difficulties, since their insulators do not come up to the requirements of the Swiss prescriptions for wet test and voltages of 44 kV or more.—We are, etc.,

For Sprecher & Schuh Co.,
J. B. RUDKIN.

London, W.C.2.
May 13th, 1922.

Morwell Brown Coal Scheme.

It is reported that the scheme for utilising the BROWN COAL DEPOSITS at MORWELL for the generation of electricity and for fuel purposes is progressing rapidly under the direction of the State Electricity Commission of Victoria. The township of Morwell is five miles from the site selected for the new power house, and, in order to avoid confusion, a new name, Yallourn, has been found for the power house and the new township which is springing up around it The principal contracts have been let for the equipment of the Yallourn power house, which will have a capacity of 50 000 kW and will contain five 12 500 kW turbo generators, one being held in reserve. The voltage of transmission will be 120 000 V.

As the power requirements of the Metropolitan area are increasing rapidly and the Yallourn power house will not be ready for two or three years, it has been decided to push on as rapidly as possible with a new power house in Melbourne, to be known as the Newport B. Station, which will later be linked up with the bulk supply. At the outset this station will have two 14 000 kW turbo-generators, one being for stand-by purposes. It is hoped that this station will be in operation by May, 1923. The Commission anticipate being in a position to supply raw brown coal from Morwell to the public next month. An inclined approach to the surface of the coal is being constructed, and two "Bucyrus" shovels, with a capacity of 2½ and 3½ cubic yards respectively, will be used for excavating both the overburden and the coal. From the open out the coal will be transported to a crushing and screening plant by a system of endless rope haulages. In view of the encouraging results obtained in other parts of the world from the use of pulverised black coal as a fuel, the Commission intend to install an experimental plant for the production of brown coal in powdered form and to investigate its suitability for boilers.

District Industrial Councils.

The second annual report of the District Industrial Council No. 5 (West Midlands Area) of the Electricity Supply Industry has been issued, and states that many matters engaged the attention of the Council during the year ended March 31. The business was conducted throughout in a spirit of reasonableness and with an obvious desire on the part of all concerned to arrive at fair decisions.

The Council is composed of twelve employers' and ten trade union representations, and Mr. R. A. Chattock was re-elected chairman and Mr. E. J. Jennings, secretary and treasurer. Seven meetings of the Council and seven meetings of the Standing Committee were held, and among the matters dealt with were (1) the change made in the constitution of the National Council by which, instead of being represented by nominees of employers' associations, the employers' side consists of representatives from the various District Councils, and (2) working conditions and wages adjustments.

Working Conditions.

The Council determined that the standard conditions were more favourable than the conditions of service obtaining in many parts of the district previously, and that such standard conditions must be regarded as a whole. It was held, therefore, that it would be wrong in principle for employers to be entitled to select the best of such model conditions and at the same time to retain certain of the former conditions that were more favourable to them.

As the result of negotiation with representatives of small undertakings (of 100 kW or less) a modified set of working conditions was approved and has now been ratified by the National Council.

Adjustments of Wages.

The District Council approved a scheme, which had been prepared in February, 1921, for the adjustment of wages to correspond with variations in the cost of living. This scheme was not confirmed by the National Council, which decided that the question was one to be dealt with on a national basis. In November, 1921, the latter formulated a slightly different scheme. From November 15, 1921, when the National Agreement was adopted, three revisions of wages have been made to date under it—viz., November 15, 1921, January 1, and April 1, 1922. The collective effect of these revisions was a further reduction of 2½d. per hour, which with the 6s. 9d. previously made, represented a total reduction in wages during the year of 16s. 6½d. per week (47 hours) or 10s. 9d. per week (48 hours).

Engineering Employees, Short Time, etc.

It has been agreed with the A.E.U. that engineering trade employees working in electricity supply undertakings shall have their rates of pay regulated by the Industrial Council for the industry. It was agreed by the Council that where there had been a reduction in the demand for electricity by reason of trade depression it was competent for undertakers to reduce temporarily the working hours in agreement with the Union representatives so as to obviate as far as possible the discharge of employees, and the undertakings concerned followed this procedure. All the employees, with few exceptions, have now reverted to full-time working.

In regard to the model constitution for Works Committees drafted by the National Council, the District Council approved in principle the setting up of Works Committees, but the Standing Committee reported that, in their opinion, the details of the constitution of such Committees should be left to the decision of the undertakings individually.

G.E.C. Fittings at Drury Lane.

The whole of the electric light fittings at the Theatre Royal, Drury Lane, which has lately been re-opened after being reconstructed and redecorated, have been designed and manufactured by the General Electric Company. In addition to the main fittings shown in the illustration, subsidiary fittings, such as "exit" signs, ceiling fittings in lobbies, police lights, etc., were also supplied by the firm. As will be seen from the illustration, the fittings are executed in the Early Empire style which is characteristic of the interior decoration of the theatre.

The auditorium is illuminated from the ceiling by a central fitting and five smaller ones of similar type. The main fitting, which is arranged for 30 lights, is 8 ft. in diameter, and weighs 15 cwt. It consists of a large upper corona surrounded by six 3-light flambeau brackets, a lower corona completing a panelled basket, the whole being carried out in cast brass finished a rich dark ormulu judiciously relieved with blue enamel enrichment. The panels are glazed with heavy cut plate glass, and the fitting is completed by a lower cut glass bowl. The impression conveyed by this fitting is one of massive form retaining the necessary spirit of delicacy and refinement which is so characteristic of this period. The five subsidiary fittings are of similar design, but are without the upper corona and brackets.

Numerous two-light flambeau brackets on the box and circle fronts give additional illumination, and between the boxes are installed four large standards on black marble bases with ormulu enrichment.

Standard for Main Auditorium Boxes.

Main Auditorium Fitting.

Bowl Pendant for Corridor.

Pendant for Boxes.

Two-Light Fitting for Circle Pilasters.

Two-Light Flambeaux for Circle Fittings.

In the boxes, bowl pendants finished dark ormulu and blue with silk cord suspension and "Equiluxo" glassware are installed. Ceiling fittings of the same type provide the main illumination for the circles, and are supplemented by three-light flambeau brackets applied to the front of decorative pilasters.

The main entrance contains a central gilt electrolier with cut plate glass panels and bowl and six outside arms carrying pendant lights. On the staircase the newel lights are rich gilt with flambeaux.

We are indebted to the proprietors of the Theatre Royal for permission to publish this description.

The Minister of Transport proposes to confirm the special order authorising the Midland Electric Light and Power Company to supply electricity in the rural districts of Atherstone, Nuneaton, Tamworth, Hinckley and Market Bosworth. Any objections must be sent to the Ministry of Transport by June 3.

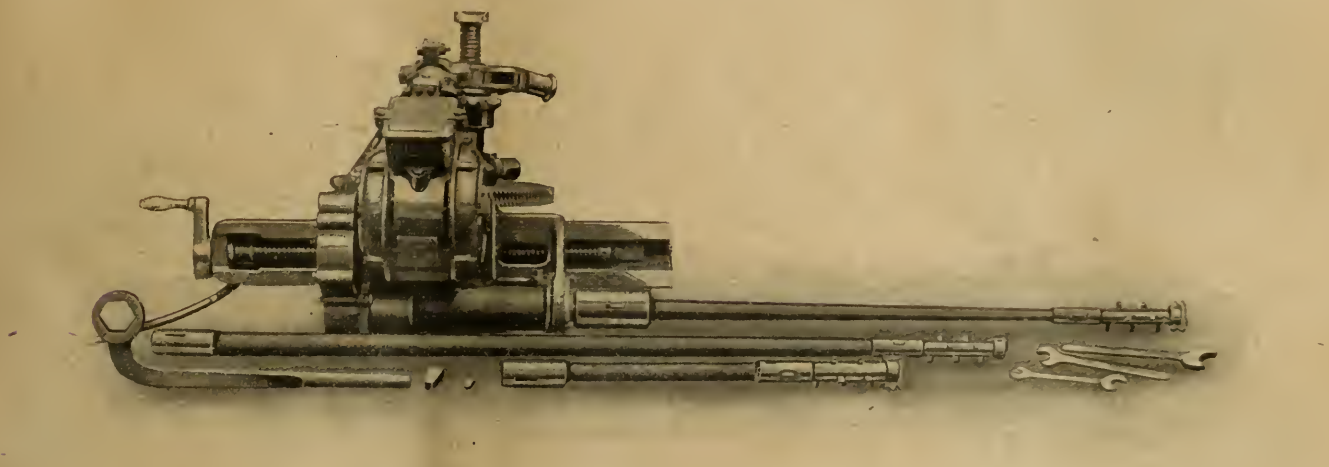
Skelton and Brotton Urban Council have decided to reduce the charges for electricity from 6d. to 5½d. per unit for lighting, and from 2½d. to 2¼d. per unit for power, cooking and heating. A discount of 5 per cent. is to be allowed on all accounts paid within 14 days.

The "Hardy-Bedford" Coal Cutter.

The patent "Hardy-Bedford" electrical coal cutting machine, recently improved by the HARDY PATENT PICK COMPANY, is claimed to be the first successful attempt to solve the problem of a light heading machine for the electric drive, but of the same weight as, and to do similar work to the small air driven percussive heading machines.

This new machine cuts the coal by rotary action. The general construction is clearly shown in the illustration. The machine itself is fixed in position and held up to its work by means of a column or standard provided with jack-screw and toothed head and foot. The power unit is a 1½ H.P. a.c. motor, which can be wound to suit the voltage, phases and periodicity of the current in use at any particular mine. The motor drives the main cutter shaft through a train of machine-cut gearing, at a speed of 350 revs. per min. In the cutter shaft are placed the cutter bars of various lengths fitted at the ends with cutting picks of special design. The whole machine is seated in a cone cup forming part of a clamp which is attached to the column. This clamp carries a worm, the teeth of which mesh with those of a worm wheel bolted rigidly on the column. The whole of this attachment is mounted on a patented ball-bearing device which allows the machine to be moved round the column with a minimum effort.

In operation the cutter bar is fed forward into the coal to a depth of from 2 in. to 6 in., and then by means of the worm handle the machine is moved round the column, cutting with the side of the cutters. An arc shaped undercut is thus made, and this increases in depth and width as the repeated cuts are effected and as each successive length of cutter bar is inserted in the main cutter shaft. The machine will cut from 12 ft. to 15 ft. in width by 4 ft. 6 in. in depth from one setting, and the height of the cut is about 3½ in. As soon as the desired depth is obtained at the centre of the working place, the operator squares out the corners of the arc-shaped cut until the undercut or channel is of uniform depth at every point. When pillars are taken out, or, in working on a longwall face, the successive cuts break into one another, a continuous undercut the whole length of the coal face, whatever this may be, is obtained.



THE HARDY-BEDFORD ELECTRICAL COAL CUTTING MACHINE

The Cutting Speed.

The cutting speed of the machine naturally varies with the hardness of the material. Speeds as high as 120 sq. ft. per hour have been attained, and under ordinary circumstances the output of the machine is approximately the same as that of a compressed air driven percussive heading machine. The whole of the machine, apart from the motor, runs in an oil bath, and is fitted throughout with ball thrust and line bearings, thus attaining economy of power in a very great measure. A percussive air driven heading machine requires 25 B.H.P. to drive it, whereas this machine, we understand does approximately equal work with an expenditure of 1½ B.H.P. The weight of the coal cutting machine proper is about 280 lb., and the total outfit weighs, packed, about 8 cwt.

A Journal of Scientific Instruments.

The INSTITUTE OF PHYSICS has under consideration the publication of a journal dealing with methods of measurement and the construction and use of instruments, to be called "A Journal of Scientific Instruments." In Germany there are some four or five journals which cover this field, and one of these, which devotes itself entirely to the subject of scientific instruments, has been of great influence in imparting a sense of the importance of scientific methods in the study of technical and industrial problems. Research workers and manufacturers in this country have long felt the need of such a journal. The journal will be managed by a committee appointed by the Institute of Physics on which the Department of Scientific and Industrial Research and the National Physical Laboratory will be represented, and the editorial work will be carried out at the N.P.L., assisted by a scientific advisory committee appointed by the Institute of Physics. It will probably consist of 32 pages, and will be published monthly at 2s. 6d. per issue. The Institute will only find it possible to make itself responsible for the journal if its financial position is secured; and as a means of ascertaining what support may be expected a specimen number for free issue is now being issued. Anyone desiring a copy of this number is asked to apply to the Secretary of the Institute of Physics, 10, Essex-street, London, W.C.2, and to enclose 6d. to cover postage.

A new Bulletin (No. 15) entitled "Street Lighting by Gasfilled Electric Lamps" has recently been issued by the GENERAL ELECTRIC COMPANY. The publication is a complete handbook on modern street lighting practice, and in addition to valuable technical data contains particulars of complete ranges of lanterns suitable for every street lighting requirement. Noteworthy features of the Bulletin are the polar curves and illumination data provided for the more important types of lanterns, and the very full instructions for calculating the size of lamp required.

Hydro-Electric Power in New Zealand.

The Minister of Public Works recently made a statement on the progress made in HYDRO-ELECTRIC POWER DEVELOPMENT IN NEW ZEALAND. He anticipated that at Mangahao 24 000 H.P. would be available by the end of next year, while works to supply 1 000 H.P. were under construction at Waikaremoana. Until better financial conditions prevailed he did not anticipate that either the main development at the latter place or the Arapuni scheme would be proceeded with. The Arapuni scheme should take precedence of all the smaller schemes in the Auckland district. The Government's commitments for hydro-electric developments to the end of the year 1923-1924 amount to over £3 500 000. The following expenditure, which includes money already spent, has been authorised for the various schemes up to March, 1924, or earlier dates:— Southland, £250 000; Lake Coleridge, £1 154 500; Horahora, £695 000; Mangahao, £1 218 000; Waikaremoana, £113 000; Otago £550 000.

Chicago Pageant of Progress.

The organisers of the CHICAGO "PAGEANT OF PROGRESS," to be held from July 29 to August 14 next, have expressed the hope that British goods will be shown at the exhibition, which is to be held on the Municipal Pier. (The pier, the construction of which cost £1 000 000, runs for a 1 000 yards out into Lake Michigan.) A similar exhibition last year was remarkably successful. The exhibition is to be divided into 16 trade sections, including automobiles, electrical industries, advertising and paper, &c. British firms will be charged the same rates for space as Chicago firms, viz.: $500 for an enclosed floor space of 20 ft. by 10 ft., including lighting and heating. Applications for space should be addressed to the Organising Secretary, "Pageant of Progress," 507 City Hall, Chicago, U.S.A.

Asbestos Woven Resistance Nets.

The illustrations show the asbestos woven resistance grids manufactured by A. Hinderlich. The net and grids manufactured by this firm are fundamentally composed of warps of specially spun asbestos, with wefts that consist of wire, flexible cable or strips made of nickel silver, constantan or chromo-nickel. Any necessary tappings required for variable resistances are woven firmly into place so that the completed unit is strong and durable. The units are constructed for temperatures up to 600°C.

Fig. 1.—Electric Fire with Three Nets.

The nets and grids can be made with wire free areas at the ends or in other parts, so that they can be held where desired without risk of the wires coming in contact with the supports. As many tappings as desired can be provided, and these are usually made of flexible wires. The resistance nets themselves are made either rigid or flexible, and impregnated or non-impregnated. The width of the units can be from ¾ in. up to 19 in., while the length may be up to 60 ft.

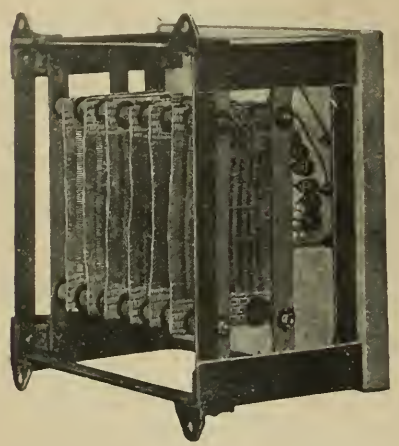


Fig. 2.—Back of Three-phase Motor Starter with Resistance Nets Built in.

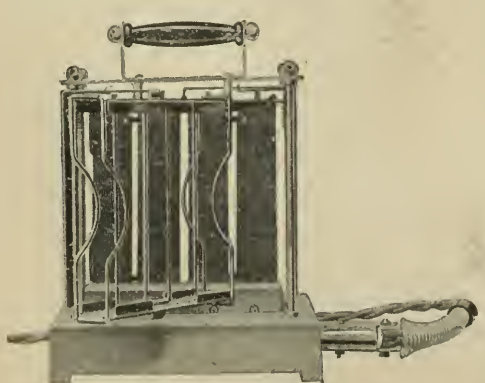
Insulating Separators.

The firm also make nets entirely of asbestos for insertion as insulating separators between adjacent current carrying nets.

The asbestos used is treated with composition, in a special manner, so as both to increase its resistance and reduce its hygroscopic nature. The insulation resistance of a cubic centimeter is 5 megohms, while the breakdown voltage through a thickness of 2 cm. was found to be 1,200 V. as a minimum. The resistances can be mounted in a large number of different ways, two of which we illustrate. The distance between two adjacent units should be from ⅝ to ¾ in. for currents up to 25 A., 1¼ in. for currents from 25 to 50 A., and 1½ in. for currents from 50 to 100 A.

A New Toaster.

Among the latest domestic labour-saving appliances to be put on the market by the Credenda Conduits Company is the "Creda" Swingate toaster, which we illustrate. The two outstanding features of this toaster are the revolving bread racks, and the ease with which the element can be replaced when necessary. The latter process occupies only a few minutes, whereas previously a very considerable time has usually been required. The toaster is supplied in all standard voltages, and has a loading of 500 W.



"Creda" Swingate Toaster.

The Consumers' Power Company of Jackson (Michigan) has 1 300 miles of transmission line, of which 526 miles are 140 000 V and the remainder 110 000 V. Thirty-one hydro-electric and steam plants are linked up.

Henley Cable Winches for India.

The cable winch illustrated is one of two designed and manufactured by W. T. Henley's Telegraph Works Co., which have recently been shipped to a large firm in India. The winches are being used in connection with the sinking of two mine shafts, where it is necessary to use motor-driven sinking pumps.

The supply cable for the pump motors was also manufactured by Henley's, and each length is 1 014 ft. and weighs 7¼ tons. It is a 0·75 sq. in. 3-core cable, rubber insulated, armoured with special high tensile steel wire, and jute braided, the over all diameter being 3⅝ in.

It was specified that the winch should be operated by hand, and it was therefore necessary to provide gearing giving a reduction of

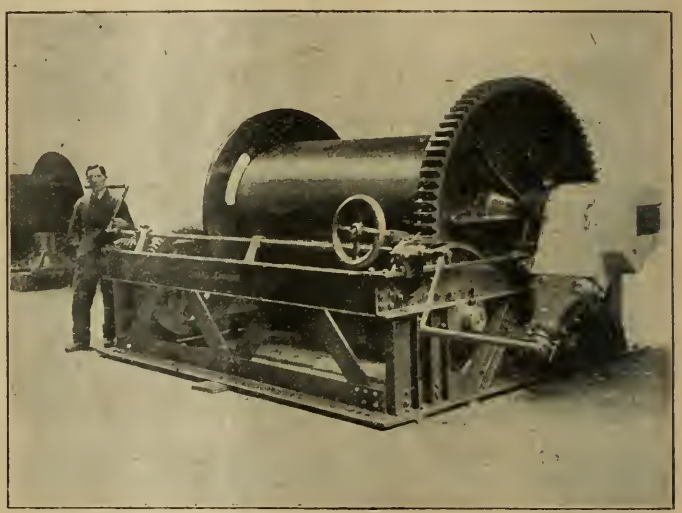


Fig. 1.—View of Henley's Mine Shaft Winch for India

524 to 1. This reduction is obtained by means of bevel, worm and spur gearing. The large spur wheel is 6 ft. 1¼ in. diameter, and, as can be seen from the illustration, is attached to one of the drum flanges.

The worm-gearing has been designed so that the angle of the worm is at the limit of its self-sustaining value, and a band brake is provided on the worm-wheel shaft so that the drum can be held in any desired position. In addition to the band brake, a ratchet wheel and pawl are fitted to prevent the drum running back when the cable is being wound up.

Method of Mounting Drum.

The method of mounting the drum is very interesting, as no shaft is used. Instead of a shaft heavy hollow cast steel trunnions are attached to the side of the drum. The necks of these trunnions run in cast iron bearings, which are supported by heavy steel framework surrounding the drum.

To enable the pump motors to be fed while the cable is being lowered, current transmitting gear has been provided, and it will be seen mounted on the right-hand side of the winch. We give a "close-up" view of this with the cover removed. Three heavy slip-rings are mounted on the end of one of the trunnions, and are supported by three insulated studs. Current is transmitted to the slip-rings by means of heavy laminated copper bands, provided with an adjustable spring tension device. The small slip-ring at the extreme end of the gear is connected to the drum and the laminated copper bands to the steel framework, so that the drum is always earthed. The cores of the 0·75 sq. in. cable for feeding the pump motors are permanently attached to the slip rings, and the cable passes through the hollow trunnion up the centre of the drum and along a hole in the opposite flange. It is next laid in a groove case in the trunnion casting attached to this flange, and is held in position by means of heavy clamps. The cable then passes through another hole in the flange and on to the barrel of the drum.

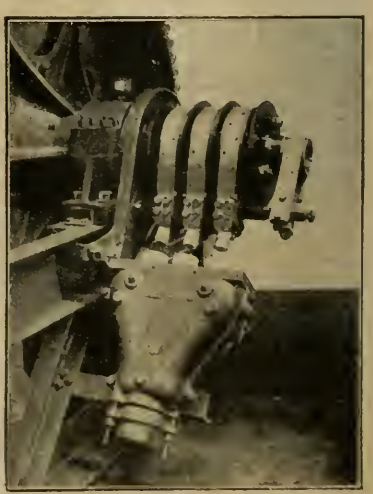

Fig. 2.—"Close Up" of Current Transmitting Gear.

An Electric Floor Polisher.

It is generally agreed among housewives that floor-polishing is the most arduous of all domestic duties, so that to many the electric polisher is a greater boon than any other electric labour-saving appliance yet invented. The ELECTROLUX polisher, which is shown in the illustration, is the smallest electric floor polisher on the market, and is claimed to be the most economical. Two sets of brushes, hard and soft, are supplied, and, as can be seen, each set is made up of two separate portions, the bristles of the

THE "ELECTROLUX" FLOOR POLISHER.

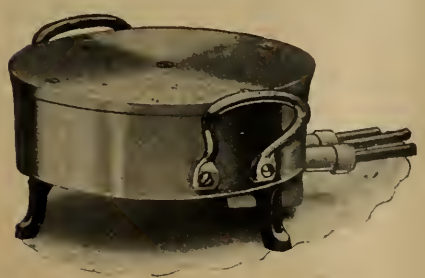
outer frame facing in the opposite direction to those on the inner block.

The method of operation is extremely simple, and the appliance is so light a child can easily use it. Before putting on the polish the floor should be rubbed over with turpentine. After this has vaporised, the polish is applied with the hard brush, and then polished with the soft brush. To change the brushes does not occupy more than a few seconds. The polisher can be worked from the lighting circuit. The loading is 140 W.

Carron Electric Cooking Appliances.

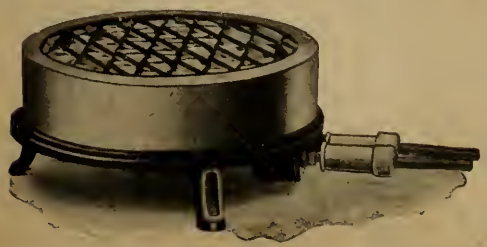
The latest pamphlet of electric cooking appliances issued by the CARRON COMPANY contains particulars of several new appliances recently put on the market by the firm. Among these are open coil boiling rings and solid type boiling plates, both of which we illustrate.

The solid top boiling plates are made in two sizes. No. 565 is 6 in. in diameter; the top is of cast iron, machined and dull nickel-plated, the casing is nickel-plated, the side handles brass nickel-plated, and the base is of cast iron. The heating elements are loaded to a maximum of from 600 to 750 W, and a porcelain metal sheathed connector, and b.c. adaptor are provided ready for connecting to the lamp-holder. No. 566 is of the same construction but measures 8 in. in diameter, and the heating elements are loaded to a maximum of 1000 to 1250 W. It is wired to two terminals, and is provided with a porcelain metal-sheathed connector, but no flexible cable.



SOLID TYPE BOILING PLATE.

No. 566 A is the same size as No. 566, but is wired to three terminals, and is provided with three single-pole connectors, arranged for three-heat control. The prices of these appliances range from 50s. to 85s.



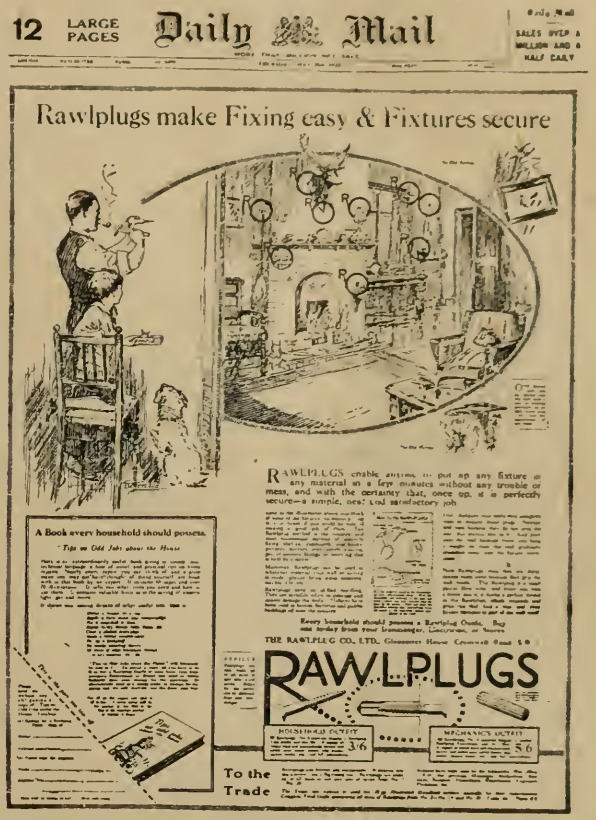
OPEN COIL BOILING RING.

The open coil boiling rings are made in the same sizes as the boiling plates, and range from 20s. to 35s. in price.

Rawlplug Enterprise.

THE RAWLPLUG CO. are having a front-page advertisement in the "Daily Mail" on Thursday, May 25.

The design, which is reproduced herewith, shows a very contented "handy man" doing a job in his house, watched by his small son—to say nothing of the dog. The appeal is clever, and the copy will send the buyer to the ironmonger or electrician for his



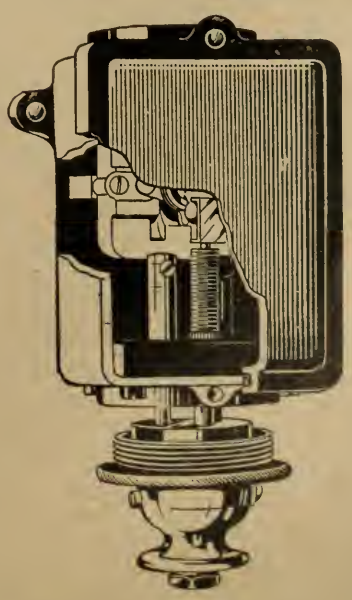
WHAT THE "RAWLPLUG" ADVERTISEMENT WILL LOOK LIKE.

supplies, which should stimulate demand, especially in view of the spring cleaning period, which the Rawlplug Co. have chosen as being notably suitable. We understand advance copies of this front page can be had on application to the company.

We congratulate the company on keeping their name before the public, which means so much in these days, and add our tribute to the worth of Rawlplugs as a labour-saving appliance.

A New Type of Switch-Plug.

The switch-plug illustrated has just been put on the market by SIMPLEX CONDUITS, LTD., to meet the demand for a thoroughly satisfactory water-tight interlocked switch and plug for use in factories, shipyards, etc. It has been designed so that the insertion or withdrawal of the plug actuates the quick make and quick break switch mechanism. This principle ensures the maximum of safety, as when the current is not required the plug must necessarily be withdrawn.



INTERLOCKING SWITCH-PLUG.

The plug is of the two-pin and earth type and is made entirely in brass; the gland fitted on the plug is suitable for twin cab-tyre cable with earthing strand. A locking ring is also provided to prevent accidental withdrawal of the plug. As will be seen, the equipment is of solid construction, and once fixed its "fool-proof" qualities should make it particularly suitable where the labour available is of a non-electrical character. With the electric drive now being introduced as the best of labour-saving methods its wide use should therefore be assured.

D

Legal Intelligence.

Dispute about Electric Light Poles.

A Divisional Court (Justices Bray and Greer) heard on Thursday last the appeal of the Rev. Edward Wm. Porter, from a decision of Judge Marchant at the Ipswich County Court that the bank into which the Ipswich Corporation, as electricity undertakers, dug six poles in Rushmere-road was not the property of the plaintiff and part of his boundary fence, but wayside greensward and part of the dedicated public highway.

Stating appellant's case, Mr. HAWKE, K.C., said Mr. Porter had brought an action for damages for trespass and for an injunction to restrain the Corporation from erecting the poles in the roadside, but the County Court Judge on April 12 last dismissed his action. The judge purported to find that the poles were put on the highway. They were erected to supply electric light to the house of a lady lower down the road. Supposing it were said, Mr. Hawke explained, that the poles were put on Mr. Porter's half of the road, there might still be something to argue, and as to two of the poles, Mr. Porter contended that if they were on the edge of the bank which constituted, with a hedge, his boundary, he had an action for interfering with his subsoil by digging 6 ft. without his consent. The other four poles were put in the bank. In the correspondence the Corporation asserted that the bank had slipped forward, helped by frost, rain and snow, and so encroached on the highway, and the poles in the bank were really put on that part of the highway on which the bank had encroached 4½ in. The plaintiff apparently was the trespasser and not the Corporation. The Corporation pleaded their statutory right as the electricity authority, and said that as to the overhead wires, the Ministry of Transport had given its consent. The judge viewed the scene, but he (Mr. Hawke) submitted there was no evidence on which the judge could find as he did.

Mr. MONTGOMERY, K.C., for the Corporation, said the important point for them was to establish that, as the electricity authority, they had power to put posts into land the surface of which was dedicated to the public as highway. Prima facie the roadway extended from the hedge on one side of the road to the hedge on the other side. He said the bank on which the hedge was placed was 2 ft. high, and, horizontally, from the line of the hedge to the edge of the grass was 2 ft. 6 in.

Mr. HAWKE asked that the case should not be sent back, but should be decided now, for life was too short to try cases twice. Mr. Porter had thrown the onus of proof on the Corporation, and they had failed to discharge it. There was nothing to rebut his evidence that the right line of bank had been adhered to.

Delivering the judgment of the court, Mr. JUSTICE BRAY said it was clear that a hedge upon a bank, with the bank, was one structure, a boundary fence. There was no evidence on which the judge could have found as he did. He found the grass was greensward, including the bank on which the four poles were placed, and part of the highway. Supposing the whole bank part of the road, no question could arise as to encroachment on the road by the bank. There could be no proper judgment except that the bank belonged to plaintiff. But it was strongly argued that what the judge found was simply that the particular points where the poles were put did not belong to plaintiff. It was not disputed that the poles were placed on the slope. The correspondence spoke of the bank creeping into the road, but the plaintiff and his gardener stated that when the Corporation men cut back the edge of the bank some years ago they provided a line which had been carefully observed ever since. The surveyor said the same, and the Corporation called no evidence to rebut this. The judge undoubtedly found, and wrongly, that the whole of the bank belonged to the highway. The judge himself viewed the bank, but he could not use the view as evidence; if he had seen anything to contradict the plaintiff's account he could have put that matter in cross-examination. The Corporation, as to the four poles, must be found to be trespassers. As to two poles, the digging for which the plaintiff said disturbed his subsoil, the lighting authority pleaded sec. 2 of the Gas Works Clauses Act, 1847, which they said entitled electric lighting undertakers reasonably to break the surface of dedicated roads. The appellant said the following proviso required that when the land of a private owner was to be disturbed his consent must first be obtained, and only the surface of the road was dedicated and not the land beneath to any extent. The proviso did not limit the powers given in sec. 6; 6 ft. was a reasonable depth for the poles, no structure beneath was interfered with, and plaintiff must lose on his contention as to those two poles. He also complained of the cutting of an Austrian pine for the electric wires, for which the Corporation said his sister gave permission; but the sister was not the owner, and when plaintiff returned home he withdrew any consent, and made it clear that he consented to nothing. Plaintiff would be given the nominal damages of 5s. for the cutting of the tree, 40s. damages for placing the four poles, and an injunction against the electric lighting authority, with costs, except that he must bear the additional costs (if any) of his plea with regard to the digging for the two other poles.

Mr. JUSTICE GREER said the digging for the two poles was done in land dedicated to the public, so the proviso following clause 6 did not apply. He was, however, a little troubled in his mind as to what would have been the effect of it if there had been a cellar or other building beneath the road into the roof of which the poles went. He referred to Thompson *v.* Sunderland Gas Company, which decided that a cellar was just as much a building, under ground, so far as electric lighting undertakers were concerned, as a warehouse was above ground.

Mr. MONTGOMERY asked for leave to appeal as the supply of electricity to a consumer was affected.

Leave to appeal was refused, but appellant agreed to a limited stay of execution.

What is Power Supply?

An action which raises an important issue for electricity supply companies and authorities came before Mr. Justice Swift on the 10th inst. The WESTMINSTER ELECTRIC SUPPLY CORPORATION sued Wykehams Studios, Ltd., for the recovery of £82 18s. 5d. for electricity supplied to the defendants for photographic purposes and for meter rent. There was no dispute as to the amount of electric current consumed, the only point being the rate of charge.

Mr. W. S. KENNEDY (for plaintiffs) said that up to May of last year the defendants were supplied with electric current on the power basis. By an agreement which was then made with the Photographers' Association a rate was arranged midway between the power and lighting charges, but defendants declined to accept the revised scale and claimed to be entitled to receive electricity at the former rates. If the contention were upheld that plaintiffs had no authority to differentiate between the various uses of power, and that, say, a big railway company must pay precisely the same for its current as, say, a consumer who had only a small lathe motor, then the supply must cease altogether, as the companies could not afford to supply electricity on those terms.

No evidence was called as it was admitted that the electricity supplied had been used for other than lighting purposes and that the figures put in were substantially correct.

For the defence, Mr. H. BLANCO WHITE said that he relied upon the case of the Attorney-General *v.* the Hackney Borough Council, and he submitted that as the supply given was for photographic arc lamps it was used for power and not lighting purposes. He contended that defendants were in the power class and were entitled to be charged not more than the least favoured of power users. What the company had done was to alter slightly their form of agreement and call it a general form of agreement for supplying electricity. The defendants originally took a supply of electricity in 1916; the agreement was terminated in 1921, and they were charged the lighting rate until Christmas, 1921, when the plaintiffs made an agreement with the Photographers' Association; the Corporation admitted that it was not a power charge at 4d. per unit. His clients were not parties to that agreement, and they said that the charge for power was 2d. or 1¼d. per unit, and as defendants were in the power class they said that they were being charged more than the maximum for power, as they were asked to pay 4d. instead of 1¼d. The Photographers' Association had admitted it was not power, and in consideration of that admission they had got a reduction of 2d., but defendants were not bound by that. He relied upon the company's advertisement that they supplied electricity for power at 1¼d. per unit.

Mr. KENNEDY admitted that the company offered to supply electricity for power at 1¼d. per unit—that was the price adopted for some cases, but not all. In each case a special charge was made. They were charging defendants the same rate as every other consumer in the district who was using the current for the same purpose under similar circumstances. There was no undue preference. In the circumstances the company were justified in charging defendants 4d. per unit.

Mr. JUSTICE SWIFT said that what the plaintiffs appeared to have done was to create a new class of consumers altogether, and to divide them into three sections—illuminating, power, and photographic—and to rate them accordingly. Had they the power to do that? As the point raised was an important one, he would take time to consider his judgment.

Right to a Trade Name.

Last week Mr. Justice Astbury heard a motion by Messrs. W. H. Dorman & Co., Ltd., for an injunction to restrain Messrs. Henry Meadows, Ltd., Wolverhampton, from using the name "Dorman" on their engines. It appeared that plaintiff company was registered in 1897 to take over the business carried on since 1872 by Mr. W. H. Dorman, who became chairman of the company. Henry Meadows Ltd., were registered in 1917. Mr. W. H. Dorman remained chairman of plaintiff company until 1911, and his son, Mr. John Dorman, was a director of it from 1898 to 1916, when he sold his shares and resigned his directorate, becoming sales manager until 1921. In September, 1921, he entered defendant company's service, becoming sales manager and a director. Plaintiff company stated, and it was not denied by defendants, that their engines were generally known as "Dorman" engines; but in March, 1922, defendants caused notices to be put in motor newspapers calling attention to an internal combustion engine made by them, described as the "Meadows-Dorman" engine, and stated to have been designed by Mr. John Dorman. They also claimed that they were entitled to use the name of Dorman for it.

After hearing counsel for the parties, his Lordship said he was of opinion there was no justification for defendant company's use of the name "Meadows-Dorman" for engines. Dorman did not form part of their title, and no business carried on by Dorman had been assigned to them. Defendants had only lately begun to advertise,

but plaintiffs had already received a letter from a firm assuming that the "Meadows-Dorman" engine was connected with them. If defendants used the description, confusion would ensue. There was no justification for the defendants' action in law, and the only question was the form of the injunction. The case was stronger than those where defendants were actually using their own name. He granted a perpetual injunction to restrain defendants from using the description "Meadows-Dorman" and from having their engines described or marked with the name "Dorman" or from using that name as part of their description without all proper precautions for distinguishing their engines from those made by plaintiffs or from leading or inducing customers to believe that their engines were plaintiffs' engines, or that there had been any amalgamation or arrangement between plaintiffs and defendants.

Re Hubert D. Carter (Bangor), Ltd.

At Bangor County Court last week an application was made for the compulsory winding-up order of Hubert D. Carter (Bangor), Ltd., electrical instrument dealers.

Mr. Burgis said the company was formed in 1920 with a capital of £5 000. The directors were Herbert and Eric Carter, the former being the promoter, and the shares were held mainly by members of the Carter family. There was also another company at Colwyn Bay, which was established in 1917 with a capital of £5 000. The Colwyn Bay Company supplied electrical appliances to the Bangor firm; the two firms had the same secretary (Mr. Rowley Redwood), the same directors, and the same auditors (Messrs. MacIntyre and Redwood). The Colwyn Bay Company had issued debentures to the amount of £2 000 to Hubert Carter. Rowley Redwood, who retired from the Colwyn Bay Company, was appointed receiver; then the Bangor Company went into liquidation, Redwood being appointed liquidator. Mr. Burgis suggested that the two companies were so closely allied that there ought to be an independent investigation. He represented Higgins, Ltd., Downes and Davies, Electrical Appliances, the General Electric Company, and another creditor with claims amounting to £360. One of the Carters had a claim for two years' salary (£978), which he was prepared to withdraw if the petitioning creditors would withdraw the demand for compulsory liquidation.

Mr. Bone, who appeared for certain creditors, assured the Judge of the honourable standing of Mr. Poppleton and Mr. Johnson, who represented other creditors, said the suggestion that Mr. Poppleton would be influenced by Redwood was absurd.

Eventually an order was made for the voluntary winding-up of the estate, the official liquidators to be Messrs. Poppleton (Birmingham) and Eaves (Manchester).

Attorney-General *v.* Oetzmann.

In this case the Ministry of Labour, on the information of the Attorney-General, sought to recover £5 from Messrs. Oetzmann & Company, being the price of a new controller drum to be used for revolving electric light advertisements supplied by the Ministry.

Mr. G. M. Hilbery (with the Attorney-General) said that the Ministry of Labour had a stand connected with the Government Instructional Factory at the "Efficiency" Exhibition held last spring at Olympia, on which was displayed a controller drum for working revolving advertisement lights. Defendants ordered one, but when the bill was sent in they refused to pay, because they alleged that it was a term of the bargain that there should be a week's trial of the drum, and they said that the apparatus was faulty.

Mr. Justice McCardie gave judgment for plaintiffs for the amount claimed. He held that there was no such term as that pleaded, and that there was no evidence to show that the apparatus was intrinsically faulty. The department could not be blamed for a very hot summer, which warped the woodwork of the sign and disarranged the apparatus so as to preclude its effective operation.

On the question of costs it was submitted that where the Attorney-General is unable to obtain judgment for more than £40 he was not entitled to any costs unless he could show that he could not have brought the action in the county court. His Lordship, after commenting on the High Court being occupied for two hours in dealing with a claim for £5, said he would fix a time for argument as to costs.

Claim for Electrical Goods.

In the Shoreditch County Court, on Friday, before Judge Cluer, Messrs. Ira Miller & Company, Ltd., sued Messrs. A. & E. Lower, of South Tottenham, mechanical engineers, to recover £7 4s. 5d., balance of an account for electrical goods supplied.

Plaintiff's Traveller said he called at the defendant's premises at Seven Sisters Road, and took orders from Albert John Lower. Accounts had been paid, but the balance was due that was sued for. In cross-examination he agreed that Mr. Lower said he had got a job on at High Wycombe, that he was a struggling man, and he could only pay on the completion of the job. His firm agreed to those terms, and the goods were supplied. Later they got a letter from the brother of Albert saying that he had heard that his brother Albert had been having some goods, but the firm were not liable.

For the defence, Albert John Lower said he at one time was manager to his brother, who was sole proprietor of A. & E. Lower.

Judge Cluer: I cannot see that the firm had to make any inquiry when the firm was "A. & E.," and they got orders from "A." Besides, here is a memorandum in which it refers to the goods supplied "to our order." Judgment was entered for plaintiffs, with costs.

Holbrook *v.* Court.

In the Mayor's and City of London Court last week J. Holbrook & Company, electrical engineers, sought to recover £69 3s. from Mr. H. J. Court, of Whyteleafe, Surrey, for an electric light installation.

The defence was that plaintiffs' representative said they had made the necessary arrangements with the local Electrical Supply Company to lay cables in defendant's road, and that they would be laid within two or three weeks. Defendant gave the order on the faith of that representation.

Plaintiffs said they did not represent that the company would lay the mains in any definite time, but they did their best to induce them to do so. Defendant replied that plaintiffs' services were useless to him as the supply was not yet in the village, because plaintiffs never got fifteen customers as arranged.

The Judge came to the conclusion that there was misrepresentation, but not fraudulent misrepresentation. He need not go into the question of whether there was any warranty or not, although he thought there was. He found for plaintiffs for the amount claimed, without costs, and for the defendant for 50 guineas on a counter-claim, with costs.

Re J. G. White & Co., Ltd.

The High Court has sanctioned a reduction in the capital of J. G. White & Co., Ltd., from £500 000 to £350 000 by writing 15s. off the 200 000 £1 ordinary shares. In 1920 the business of a subsidiary company (The J. G. White Commercial Co.) developed extensively, particularly in South America, but in the autumn of that year the company suffered severe losses by the fall in prices and in exchange. Some of the indebtedness of the Commercial Company is irrecoverable and had to be written off.

Registration of Business Names.

At Bow Street Police Court last week, Mr. Geo. Weston, who carries on business as Geo. Weston & Co., at Hounslow, was fined five guineas, with three guineas costs, for failing to register the name of the firm under the Registration of Business Names Act, 1916.

Parliamentary Intelligence.

Ayr Electricity Bill.

A Select Committee of the House of Lords, presided over by Lord Bristol, has been considering this Bill, which confers powers (*inter alia*) upon Ayr Corporation to utilise the water power of Loch Doon in the generation of electricity. Originally the Corporation desired to extend their area of supply in the southern part of the county, but this proposal was dropped, though they wish to obtain the right to supply electric power in the county if it proved desirable. The County Council withdrew their opposition on terms, but Kilmarnock Corporation, which had an agreement with Ayr for bulk supply, was given a *locus standi*.

Mr. H. P. Macmillan, K.C., who appeared for Ayr Corporation, gave a general outline of the scheme, which was promoted because of the increasing demand for electrical energy and because the present steam plant was nearly loaded to its full capacity. It was really a small and simple undertaking. The cost of the hydraulic works would be about £113 000; the power station and equipment, £43 000; the transmission system, £58 000; and general costs, £6 000, a total of £220 000. It was also proposed to increase the maximum charge to 1s. per unit, and to extend the area supplied by the Corporation, by including the southern portion of the county, with the burghs of Maybole and Girvan. The scheme would involve the acquisition of land, the erection of a power station, the turning of Loch Doon into a reservoir, etc.

Engineer's Evidence.

Mr. J. H. Rider, consulting engineer, gave technical details of the scheme, and said it was intended that a minimum of 4 000 000 gallons per day should be left in the bed of the river where it was proposed to withdraw the water for power. Arrangements might be made for a daily flow of 6 000 000 gallons, but anything beyond that would be fatal to the scheme. They could complete the works in two years from the time of starting.

Replying to Lord Novar, witness said that so far as their proposals went the scheme would be complete in itself, but that was not to say that there was no possibility of further hydro-electric schemes in the same watershed. He would foresee the time when the whole of the energy of Loch Doon would be required for Ayr.

Mr. W. A. Tait, consulting engineer, said Loch Doon was suitably situated for hydro-electric power. If the scheme were proceeded with he did not think there would be any appreciable effect on the amenity of the loch. The cost of the works were correct, and were based on 100 per cent. increase on pre-war prices. The scheme was capable of being extended in conjunction with any larger scheme that might be launched. He had seen a section of the bed of the river, and he thought that relatively small works would make a succession of pools and runs which would result in the better utilisation of the water. The scheme would be to the advantage of the mills in the vicinity of the river, because they would have a bigger storage of water and more regular flow.

On the 11th inst. Mr. Tait continued his evidence, and said that raising the dam on Loch Doon by 5 ft. would submerge about 200 acres. In the Bill the water to be reserved for the stream would be

6 000 000 gallons per day. If the dam were raised to 10 ft. it would mean an increase of £10 000 on their present estimates, and a corresponding increase on the annual charges.

Mr. Godfrey M. Taylor, civil engineer, said that, whatever compensation water was given, it must be an elastic quantity in the interests of the fish. It was for that reason that it was proposed to store 3 000 000 to 4 000 000 gallons of water for each of four successive days, and then release it on the fifth day. The storage capacity of Loch Doon, when raised 5 ft., would be 7 000 000 gallons, but under the present scheme only 5 500 000 gallons would be required.

Mr. Armistead, fishery expert, said that it was on his advice that the minimum flow of the river was fixed at 4 000 000 gallons. The river was a very fine salmon river, but its bed could be improved by making a series of pools with easy runs between. He could say that, with the works contemplated and the volume of water that was to be sent down, the proprietors on the Doon need have no fear that the stock of fish would be affected.

The Committee adjourned.

Electricity (Supply) Bill.

Mr. A. Neal, Parliamentary Secretary to the Ministry of Transport, moved the second reading of this Bill in the House of Commons on Monday. In explaining the provisions of the Bill, which has already passed the House of Lords, he said the measure proposed to complete and make workable the Act of 1919. It would give joint electricity authorities, with the approval of the Electricity Commissioners, power to borrow, and certain councils and companies interested power to lend, in respect of electricity supply works and undertakings. The measure was mainly financial, but it also contained powers to make agreements for the working of generating stations and, by consent of the authorities concerned, to extend the periods of purchase at present vested in local authorities. After referring to what was being done in other countries and to the need for economising our coal supply, he said the Bill would be of value in relieving unemployment in the best possible way.

Mr. G. Balfour moved the rejection of the Bill, mainly because, he said, he wished to secure proper and adequate control by the House over the finance of the large authorities proposed to be set up under the Act of 1919. He regarded the proposed joint authorities and the methods of finance proposed as bad public policy, which would lead, not to progress and prosperity, but to stagnation. The Bill proposed to confer powers on joint electricity authorities to borrow very large sums of money and pay interest while capital was unremunerative, and to suspend the sinking fund on unremunerative undertakings for five or six years. It also conferred certain financial powers on local authorities, which, with those conferred on joint electricity authorities, were subject only to the confirmation of the Ministry of Transport and the approval of the Treasury. He contended that financial powers should be given to the joint authorities by provisional orders, which would have to be laid before Parliament for confirmation.

Sir R. Clough having seconded the motion for the rejection of the Bill,

Sir P. Dawson said he was glad that the compulsory clauses in the Bill of 1919 were now optional, but he thought there were many clauses in the present measure which were dangerous from the point of view of the economical production of electricity. Under the Bill the main reason which now existed for local authorities producing cheap electricity would cease to exist, and instead of promoting a cheap supply it might result in a dearer one.

Mr. Myers supported the Bill, and the debate was adjourned.

German Optical and Scientific Instruments.

A Committee appointed under the Safeguarding of Industries Act is investigating the complaint made with regard to optical and other scientific instruments manufactured in Germany.

On Monday Sir Arthur Colefax (for the applicant associations) said that they would submit evidence upon a few typical standard articles, and more especially upon prism binoculars, microscopes, photographic lenses, drawing instruments, etc. The excellence of British prism glasses led the Admiralty and War Office to select them as standard articles, and at the end of the war the output capacity had considerably increased. To-day German binoculars were being sold at about one-third of the cost of similar English-made articles. He cited an instance in which £3 18s. 6d. was charged for German binoculars which before the war sold for £6 10s. British manufacturers could not possibly sell at anything like £3 18s. 6d. Apart from Government contracts for India, the British industry was practically closed down. Home manufacturers were also unable to compete with prices charged for German-made microscopes, photographic lenses, spectacles, cheap lenses and drawing instruments. In consequence some home firms were now employing less than half the number of workers they employed in 1913.

Mr. Watson Baker said that although a duty of 33⅓ per cent. had been imposed upon imported microscopes the prices of the German articles had been advanced by only 10⅝ per cent. They were hoping for an appreciation of the mark and an increase of wages in Germany. If that occurred a further duty of 33⅓ per cent. would greatly assist British manufacturers.

L.C.C. Tramways.

On the 11th inst. a Select Committee of the House of Commons passed the preamble of the London County Council (Tramways, Trolley Vehicles, and Improvements) Bill. Originally the Bill contained proposals for constructing a trolley omnibus line from Norwood Road to the Crystal Palace, but owing to the veto of Lewisham Borough Council that part of the scheme had to be dropped. The remainder of the Bill was concerned with the construction of about five-eighths of a mile of tramway along Amhurst Park, connecting the L.C.C. tramway at Stamford Hill and that of the Metropolitan Electric Tramways, Ltd. (who opposed the Bill) in Seven Sisters Road. The local authorities concerned desired that the tramway should be made, but the Metropolitan Co. opposed. The committee found that the Metropolitan Company's property would not be damaged, or in any way rendered less valuable or productive by the construction of the line.

Coal Mines (Safety Lamps).

In reply to Major Barnes (House of Commons, May 11), Sir R. Horne said that no financial assistance by way of grant or loan had been given to firms engaged in the production of safety lamps for use in coal mines for the purpose of putting down or extending their plant. With regard to Excess Profits Duty, only such allowances had been given as were authorised by the statutes relating to that duty which were applicable to trades and businesses in general, including those to which Major Barnes referred. The Commissioners of Inland Revenue were precluded by statute from disclosing information relating to the taxation of particular taxpayers.

Merchant Ships and Wireless Staff.

In reply to Mr. Maclean (House of Commons, May 15), Mr. Baldwin stated that the Merchant Shipping Advisory Committee had reported on the question of wireless watchers, and recommended that no change in the regulations was at present justified. At the same time, the Committee called attention to a lack of co-operation between operators and watchers, and to the unsatisfactory practice obtaining on some ships of taking watchers from their wireless watch for other work. Steps were being taken by the Board of Trade to effect improvement in these respects. The Committee's report was being printed.

Imperial Notes.

Coraki (N.S.W.) Council are seeking permission to borrow £6 500 for the equipment of electricity works.

The accounts of the Port Pirie (South Australia) municipal electricity department for the past year show a profit of £530. Units purchased from the Broken Hill Associated Smelters were 320 420 and sold 246 399. Income was £7 733.

The Town Clerk of Bendigo (Victoria) has written to Ballarat Council urging that the two Councils should co-operate in an endeavour to secure prompt Government action in regard to providing electricity supply at reasonable rates for consumers in country districts.

The report of the manager, Mr. Guy Allbut, on the working of the Newcastle (N.S.W.) municipal electricity undertaking for 1921, states that there was a net surplus of £10 128 os. 8d., after providing for all charges, including instalments of loans and depreciation. Revenue was £100 238, compared with £66 499 in 1920. The capital expenditure on new works was £44 173, compared with £37 062. New consumers connected were 1 997, compared with 1 325 in previous year.

The expenditure authorised to be made in the year ending June 30 next on the scheme for the exploitation of the water power of the Australian River Murray for generating electrical energy is £80 000, which will be spent chiefly on the Hume reservoir, the Lake Victoria (South Australia), storage and locks at Torumbarry and at Wentworth, near the junction of the Murray and the Darling. The full scheme will take eight years to complete, and will involve the construction of 35 locks and weirs. Work is proceeding on No. 3 lock, four miles below Kingston (South Australia).

Wireless Wave Meters.

On Monday the Royal Commission on Awards to Inventors heard a claim by Prof. J. S. E. Townsend, in respect of a wave meter. At the time the invention was made Prof. Townsend was an officer in the R.N.V.R., his duties being to instruct officers in the theory and practice of wireless telegraphy.

Mr. Whitehead, for the claimant, said the invention indicated the particular wave which an instrument was emitting when used as a transmitter or the length of the wave which the instrument was receiving when operating as a receiver.

Prof. Townsend and Prof. Whiddington gave evidence in support of the claim, the latter laying stress on the fact that the invention could be used for continuous wave work, and that it was extremely accurate.

Mr. Trevor Watson (for the Crown) said that about 2 000 of the wave meters were in use towards the end of the war, and he admitted that the instrument was the best of its kind at that time.

The Commission reserved their decision.

Electricity Supply.

WINCHESTER City Council has authorised the expenditure of £250 for the purchase of electric cookers for hiring out.

The Electricity Commissioners will hold an inquiry on the 30th inst. at LYME REGIS Town Hall into the Council's application for a Special Order to supply electricity in the borough and the adjoining parish of Uplyme.

The ELECTRICITY COMMISSIONERS WILL HOLD AN INQUIRY at the Middlesex Guildhall, Westminster, London, on May 30, at 10.30 a.m., and following days if necessary, into the application of the South Eastern and Chatham Railway for permission to establish a generating station on Angerstein's Wharf, Charlton, Kent, and into that of the West Kent Electric Company to establish a generating station at Belvedere, in the Urban district of Erith. Anyone interested in the applications of either company may attend.

At a meeting of ACCRINGTON Town Council on Monday it was stated that the revenue of the electricity undertaking had suffered as a result of the coal strike, &c., and the sale of current was down by a million units. Notwithstanding the increase in price the receipts had only increased by £3 500. Owing to the fact that generating costs had been reduced from £71 000 to £45 000 the loss last year of £8 800 had been turned into a profit of £13 790. After the appropriation of various sums they had a total profit for the year of £12 640. Until industrial conditions became more settled nothing could be done with regard to a reduction in price.

A block of twelve MODEL DWELLINGS in SHOREDITCH is to be lighted electrically by the London County Council. The Borough Council will fit the tenements for lighting, cooking and water heating, the County Council bearing half the cost (£15 each), which is claimed to be less than the charge for installing gas fittings. Electricity will be supplied at a flat rate, the average charge for a three or four-roomed tenement for lighting and water heating being estimated at 2s. a week, and for a five-roomed one, 2s. 4d. When current is not used for lighting it operates automatically for heating water. For cooking, a separate meter will be installed, and electricity will be supplied at 2d. a unit.

New Schemes and Mains Extensions.

PORTSMOUTH Town Council has received sanction to a loan of £3 000 for the extension of the engine house at the Electricity Works.

BERWICKSHIRE County Council have granted permission to the Greenlaw Electric Supply Co. to erect overhead transmission lines in the town.

CROYDON Town Council have applied for a Special Order to supply electricity to Addington at an estimated cost of £1 000. Owing to the increased demand for electricity at Croydon, £12 084 is to be expended on additional plant.

BRADFORD Corporation have decided to inaugurate a modified scheme of street lighting in an endeavour to secure further economy. Only about half the present number of lamps will be lighted, and the experiment will last for one month.

A limited company has been formed at CORWEN to carry out a combined water and electricity scheme for the town. Electricity will be generated at the Cynwyd waterfalls, about two miles away, where two turbines will be fixed, with a station in the centre of the town.

WARMINSTER Electric Supply Company have acquired an old foundry near the Market Place for use as a generating station. Arrangements have been made for the mains to be extended to the village of Sutton Veney, and it is hoped to have electricity available by Christmas.

WORCESTER City Council are making application to the Electricity Commissioners for a Special Order to enable them to supply electricity outside the boundary of the city and within a radius of three miles from the Cross at Worcester, and to supply in bulk to the Shropshire Power Company and the Malvern Urban District Council.

The Electric Supply Corporation are asking the Electricity Commissioners to rescind the HITCHIN ELECTRIC LIGHTING ORDER, 1902, and the EXMOUTH ELECTRIC LIGHTING ORDER, 1900, and to grant new orders authorising electricity supply in the respective urban districts of Hitchin and Exmouth as constituted at the date of the proposed Orders.

Alteration of Charges.

TONBRIDGE Urban Council has abolished the minimum charge of £2 per annum hitherto levied on consumers of electricity.

BROMWICH Electricity Committee recommend a further reduction of 12½ per cent. to power consumers as from the March (1922) meter readings.

SUNDERLAND Town Council has authorised the following reduced scale of charges for the supply of electricity for heating and cooking purposes, in place of the previous rate of 2½d. per unit:—Not exceeding 500 units per quarter, 2½d. per unit; 500–1 000 units, 2¼d.; 1 000–1 500 units, 2d. per unit; 1 500–2 500 units, 1¾d.; exceeding 2 500 units, 1½d.

Personal and Appointments.

PROF. R. W. CHAPMAN has been elected President of the INSTITUTION OF ENGINEERS (of Australia) for the year 1922.

SIR RICHARD GREGORY has accepted the position of President of the Decimal Association in succession to the late Lord Belhaven and Stenton.

Owing to his business premises in Packer's Row, Chesterfield, having been demolished, Mr. EDGAR R. MORRIS, electrical engineer, has taken temporary premises in Elder Yard.

SIR THOMAS HENRY HOLLAND has accepted the invitation of the Governing Body of the Imperial College of Science and Technology, London, to be Rector of the College, in succession to Sir Alfred Keogh, who will retire on September 1 next.

PROF. C. L. FORTESCUE, of the Royal Naval College, Greenwich, has been appointed to the Chair of Electrical Engineering at the City and Guilds (Engineering) College in succession to Prof. T. Mather, who is resigning at the close of the present session.

MR. J. W. BISPHAM, of the London County Council service (Technology Section), has been appointed principal of the Borough Polytechnic Institute, to fill the vacancy caused by the retirement of Principal C. T. Millis. He will take up his duties in September.

MISS A. C. DAVIES, of the Royal Holloway College, Englefield Green, Surrey, has been awarded the annual international prize of 1 000 dollars given by the American Association to Aid Scientific Research for her paper on "The Investigation of Critical Electronic Energy Associated with the Excitation of the Spectra Helium." Thirteen papers were received—from Great Britain, six; United States, five; Australia, one; Russia, one.

MR. C. MITCHELL, who recently retired from the position of works manager of the Marconi Wireless Telegraph Company, Chelmsford, after 16 years service, has been presented with an antique walnut bureau and a silver cigar case by employees who were under him ten years or over. Mr. A. Eddington, in making the presentation, referred to the great service rendered by Mr. Mitchell in being instrumental in forming the men's and girls' club rooms and the fine sports ground.

Recent appointments to the staff of the Technical College, Bradford, include Mr. R. E. STRADLING, as head of the Department of Civil Engineering, and Mr. HENRY J. B. CHAPPLE, as lecturer in Electrical Engineering. Mr. Stradling was formerly at Bristol University and is now Lecturer in Civil Engineering in the University of Birmingham. Mr. Chapple is at present undertaking post-graduate work in wireless telegraphy and telephony at the City & Guilds of London College. He was for some years engaged in practical electrical work at Portsmouth.

Business Items, etc.

Mr. Wm. H. Bill has ceased to be a partner in the firm of BILL & BERRY, as from March 25 last. The firm will be carried on as before by Mr. James H. Berry as sole proprietor, who will discharge all the liabilities.

AUTOMATIC AND ELECTRIC FURNACES, LTD. inform us that in response to enquiries, they have introduced a marine-type of Wild-Barfield electric furnace for use on board ship. This type of furnace has been inspected by Admiralty experts and passed for use on H.M. ships.

U.S.A. Electrical Manufactures.

An analysis of the CENSUS OF ELECTRICAL MANUFACTURES in the United States for 1919 appears in the "Electrical World" of April 22. A comparison is made with the position in 1914, and though both years were abnormal, it is clear that enormous progress was made in the period. The total value of the electrical products in 1919 is given as $997 968 119, against $335 170 194 in 1914, and of subsidiary products as $21 092 700, a total of $1 019 060 870, against $359 432 155. Generating plant and parts increased to $86 266 114, from $17 865 542, transformers and feeder potential regulators to $53 495 570 from $28 276 338, and motors (excluding starters or controllers) to $116 893 038 from $44 176 235. There were also large increases in the values of electric locomotives, batteries (storage and primary), carbons, searchlights, incandescent lamps, telegraph and telephone apparatus, domestic devices, switchboards, radio apparatus, &c. In fact, the only heading showing a reduction is arc lamps, though in the actual number manufactured (but not value) carbon filament lamps also showed a slight drop.

A notable feature was the increase in the size of the generating units and the demand for large transformers. Though the carbon lamp production remained stationary, the tungsten lamp output rose to 211 383 193 from 74 434 059 in 1914. The demand for domestic electric apparatus and devices is clearly shown by the fact that their value was about fourteen times that of 1914. Heaters, stoves and ranges, grills, toasters, flat-irons, vacuum cleaners, vibrators, cutters, &c., all seemed to share in the popularity of domestic appliances. Farmhouse plants and radio apparatus were also much in request.

Electric Traction.

WALSALL Town Council has decided to reduce by 20 per cent. the charge for electricity supplied to the Tramways Department.

SUNDERLAND Corporation has decided that while repairing the tramway track in Tatham-street they will provide a new interlacing line at an estimated cost of £450.

READING Corporation tramways show a net profit of £2 988 this year against a deficit of £14 023 last year. The number of passengers carried during the year was 11 349 857, a decrease of 1 326 240.

The report of Sir William Marwood and Colonel J. W. Pringle recommending the erection of CENTRE POLES in PRINCESS STREET, Edinburgh, has been issued by the Ministry of Transport as a White Paper.

BARROW Electricity Committee have notified the Tramways Committee that they are unable to reduce the charge for current for traction purposes, but for lighting the charges will be reduced from 8d. to 2½d. per unit.

The Standard Electric Co. have obtained a concession from the British Electric Federation, Ltd., for erecting illuminated signs on the electric light standards and tramway poles in SWANSEA, from which the Corporation will obtain a revenue of about £1 600 for the electricity used.

Institutions.

The annual conversazione of the INSTITUTION OF ELECTRICAL ENGINEERS will be held on Thursday, June 29, from 8.30 to 11 p.m., at the Natural History Museum, South Kensington.

The following members have been nominated to serve on the WIRELESS SECTION COMMITTEE OF THE I.E.E. for 1922–23: *Chairman*—Prof. G. W. O. Howe. *New Nominations for Membership of the Committee*—S. Brydon, J. St. Vincent Pletts, Captain H. R. Sankey, R. L. Smith-Rose. The following will continue to serve as members of the Committee: B. Binyon, R. C. Clinker, Dr. W. H. Eccles, Prof. C. L. Fortescue, G. H. Nash, C. C. Paterson, Captain H. J. Round, L. B. Turner.

In a lecture on "Brakes for Tramways and Road Vehicles," delivered last week before the YORKSHIRE ASSOCIATION OF CIVIL ENGINEERS, Mr. J. W. Dawson described the method of braking in operation at Bradford. Professor Charnock, who presided, said that nearly all tramway accidents in this country had been traced to inefficient or defective brakes, and the operation of stopping a car was not by any means the simple matter it was sometimes assumed to be. A passenger who stopped a car, either in entering or leaving, was responsible for the expenditure of an amount of energy which would suffice to carry him nine miles. The energy absorbed in starting and stopping the cars on a given tramway system was enormous, and it had been ascertained that in several large cities as much as £50 000 was expended annually in stopping cars.

Arrangements have now been completed for the summer meeting of the NEWCOMEN SOCIETY, which is to be held on Thursday and Friday, June 1 and 2. On the first morning a conducted tour will be made through the engineering collections of the Science Museum, South Kensington, followed in the afternoon by a conducted inspection of the roof of Westminster Hall, by kind permission of Sir Frank Baines, Director of Works; a visit to the Clockmakers Company's Horological Collection, and, if time permits, to the Guildhall. At 7 p.m. the party will meet for dinner at the Engineers' Club, Coventry Street, W.1 (morning dress, probable cost 5s. each). On Friday morning a visit will be made by motor coach to the Rotunda Museum, Woolwich, and after lunch at the Ship Hotel, Greenwich, the Naval Museum will be inspected. At 4.30 p.m. the party will leave for Deptford, where a visit will be made to Boulton and Watt Engines, 1812 and 1824, M.W.B. pumping station, Brookmill Road, by kind permission of Mr. T. Melhuish, District Engineer.

Linke-Hoffmann Works.

"The Times" Berlin correspondent states that in the ANNUAL REPORT OF THE LINKE-HOFFMANN WORKS details are given of the arrangement come to with the Allgemeine Elektricitats-Gesellschaft in view of the future electrification of the German railways and the expected demand for electrical locomotives. For this purpose a new group has been formed consisting of the Linke-Hoffmann Works, the A. G. Laushener, and the A.E.G., and by these the "Sgahl and Walzwerk Hennigsdors" has been founded. The Linke-Hoffmann and A.E.G. have acquired an interest in the Rhenische Metallwaaren and Maschinen Fabrik of Düsseldorf, and the former's holdings in J. P. Goossens Lochner and Company and Rudolf Lochner and Company have been increased. The capital of certain subsidiary companies has also been increased. In 1920 the Linke-Hoffmann raised its capital by 56 000 000 marks, and of this increase the A.E.G. has taken over 30 000 000 ordinary shares. An increase of 80 000 000 marks was authorised last December, the greater part of which is being expended in improving the company's holdings in other countries. The Linke-Hoffmann gross profits for the year 1921 were 218 019 928 marks, compared with 82 000 000 in 1920 and 26 000 000 in 1919.

Possible Trade Openings.

The Municipal Council of DEN HAM (province of Overijsel, Holland) has decided to proceed with the electrification of Den Ham and Vroomshoop, for which purpose a loan of Gld.115 000 will be issued.

A correspondent in NOVA SCOTIA asks for the addresses of United Kingdom manufacturers who can supply wireless apparatus and sets suitable for home use. Particulars from the Canadian Government Trade Commissioner's Office, Portland House, 73, Basinghall Street, London, E.C.

An electrical engineer in Weston, ONTARIO, desires to obtain the representation of United Kingdom manufacturers of machine tools, coal handling machinery, boiler house plant, etc., on a commission basis, for the Province of Ontario. Particulars from the Department of Overseas Trade. (Reference No. 522.)

In connection with the invitation by the SIAMESE DEPARTMENT OF POSTS AND TELEGRAPHS for tenders to be submitted by June 28 for telegraph and telephone materials, the Acting Consul General at Bangkok has now forwarded to the Department of Overseas Trade a copy of the form on which quotations are to be made. The form specifies the following material as being open to tender: galvanised iron wire; insulators, white Cordeaux pattern; G.P. insulated submarine telegraph cable; twin opening out wire; rubber cable; galvanised steel suspension wire for aerial cable; magneto ringing wall telephones.

A Committee has recently been formed in Vladivostock for the purpose of rebuilding the town of NIKOLAEVSK-ON-AMUR, which was burnt down in 1920 and which is at present under Japanese administration. The plans of the Committee provide for the establishment of a town electric lighting station, a commercial port with wharves, warehouses, and full equipment both for marine and river transport, the installation of a sewage system, water supply, and telephone service, and also for the erection of 1 500 dwelling houses. The Committee invites the co-operation of British enterprise and capital in the work of reconstruction. Further details can be obtained from the Department of Overseas Trade.

A company who maintain a telephone system in WESTERN CANADA have intimated to Mr. L. B. Beale, H.M. Trade Commissioner for Western Canada, that they are prepared to do business with firms in this country who can quote advantageous prices and delivery dates. The company are accustomed to purchase lead-covered, paper-insulated cable, 22 B. & S. gauge, in standard sizes up to 800 pairs in large quantities of some 480 000 lb., sufficient for a year's work, and are now in the market for such cable. The name and address of the firm to whom communications should be addressed can be obtained on application to the Department of Overseas Trade. The import duty on telephone cable of United Kingdom manufacture is 20 per cent. *ad valorem*, as against 30 per cent. *ad valorem* in the case of United States manufacture, to which must be added in each case a sales tax of 4 per cent. of the duty paid value. In estimating the cost of delivering material in British Columbia, the advantages in the matter of cheap freight rates to be secured by shipment via the Panama Canal should also be considered.

Miscellaneous.

The death occurred last week at Bridgend, at the age of 73, of Mr. JOHN WILLIAMS, one of the pioneers of the Ogmore Valley Electric Light Company.

On the last line but one in the second column of our leading article on International Radio-Communication which appeared on p. 552 of our last issue 150 mV should read 150 μV.

"The Cost Accountant," the official journal of the Institute of Cost and Works Accountants, starts its second volume with the June number, and will contain the first instalment of a new series of articles by Mr. C. W. Charlesworth, F.C.W.A., entitled THE INTERPRETATION AND ANALYSIS OF ELECTRICITY SUPPLY COSTS.

LICENCES OF RIGHT have been granted to the K.W. Ignition Co. for Patent No. 105 328 (3 268/17) for "improvements in impulse starting mechanisms for the ignition magnetos of internal combustion engines," and to P. F. Brittain for Patent No. 135 747 (8 560/19) for "improvements in or connected with motors for dynamo-electric machines."

The forty-third annual CANADIAN NATIONAL EXHIBITION will be held at Toronto from August 26 to September 9. United Kingdom firms desiring to secure space should apply to the Secretary, Canadian National Exhibition, Lumsden Building, West Adelaide Street, Toronto. A Bureau of Information will again be maintained by H.M. Trade Commissioner Service in Canada, at which trade literature, small attractive posters, samples, etc., may be displayed, free of charge. Catalogues, etc., of electrical machinery and appliances; mining machinery and supplies, electrical railway equipment; scientific instruments, etc., are specially mentioned as being useful, and should be sent direct to H.M. Trade Commissioner, 24, West Adelaide Street, Toronto, not later than June 30. Leaflets issued by the Exhibition authorities, copy of correct form of invoice, etc., can be examined at the Department of Overseas Trade (Canadian Section). (Ref. D.O.T. 4985/FB/PN.)

Companies' Meetings, Reports, etc.

The English Electric Company, Limited.

Presiding at the annual general meeting of the above company on Tuesday, May 16, Sir Charles E. Ellis, G.B.E., K.C.B. (chairman of the company), said that the balance sheet showed for the first time the full liability for the note issue, but there was a considerable reduction in sundry creditors and credit balances. On the assets side there was an increase of nearly £700 000 in land, buildings, plant, machinery, etc., while interest in subsidiary and other companies was reduced by £825 000. These differences indicated further progress in the absorption of the constituent firms. The company's stocks had been much reduced during the year both in quantity and value, as they were able to foresee in 1920 that, although orders continued to flow in, the market was becoming exhausted. In addition to making a reduction in quantity of stocks they had met the heavy fall in the market value of all materials by a special writing down to a figure representing to-day's value or less.

Unprecedented State of Trade.

Turning to the profit and loss account the available balance was slightly in excess of that last year. The net profits brought to credit included dividends received from subsidiary companies and amounts transferred from reserves previously set aside and no longer required. In considering what dividend should be paid they had felt bound to look ahead and there they saw uncertainties on every hand. The state of trade was unprecedented, and the engineering industry had to face peculiar industrial difficulties. In recommending a dividend on the ordinary shares at the rate of 5 per cent. per annum, the directors considered that they had reconciled the natural expectations of the shareholders with the needs of a difficult and obscure period to come.

Need for Private Enterprise.

Important steps had been taken to effect every possible economy throughout the company's organisation, but their selling organisation at home and abroad had been increased and strengthened. The chaos in many of our best markets and the apparent failure of any scheme on the grand scale to breathe new life into the trade of Europe had produced a situation without precedent in British industry. He was strongly of opinion that the way out of most of the present difficulties would be through the efforts of private enterprise. So strongly did they hold this view that they had recently, with five powerful associates of world-wide reputation, formed the Power and Traction Finance Company, Ltd., with the object of dealing with comprehensive engineering contracts on a large scale. The electrical industry had been less seriously affected than many others, and during the past year they had secured many important contracts, including the complete central station for the City of Leicester, important railway electrification contracts in Spain and Japan, and others. There were signs that public works too long delayed must shortly be put in hand, and competition by Germany and other countries with depreciated currencies was not so serious as the abnormal rates of exchange would appear to imply.

The Engineering Lock-out.

The Chairman concluded :—

Perhaps the most disturbing feature in the prospects for the electrical industry is the continuance of the engineering lock-out. If the favourable view with which foreign buyers have regarded the industrial stability of this country in the past is to be threatened by disputes such as this, the trade revival in this country may be indefinitely postponed. In this connection the remarks of my colleague Lord Meston, speaking the other day as chairman of the Calcutta Electric Supply Company, are particularly apposite. He said : " Disputes which mutual forbearance might obviate, unless they are shortly abated, will surely drive concerns like ours, however genuine our patriotism, to place our orders for heavy electrical plant outside England."

This is neither the time nor place to discuss the merits and demerits of the engineering lock-out, but it is in my judgment certain that the vast number of workmen and employers are prepared to take the common-sense view that by real co-operation and not by abuse of power on either side are the security of one class and the aspirations of the other to be achieved. Whilst expressing a determination loyally to support the majority of the great Federation to which our trade is allied, we are bound to say that in all our works the relations between our workpeople and ourselves are excellent in every way. The damage to British trade in the eyes of the world by the present serious labour dispute in this country will be almost irreparable unless it be brought to a rapid conclusion, and I sincerely trust that the joint meeting which is to be held to-day will be the precursor of a settlement satisfactory to both parties. It may be that there are extremists on one side or the other, but whether that is so or not, a most grave responsibility rests upon the negotiators which can only be met by a policy of co-operation and goodwill.

The Castner-Kellner Alkali Company announce a dividend of 8 per cent., actual, for six months.

The dividend for the year of the French Thomson-Houston Company remains unchanged at 45 frs. per share.

The Indian Electric Supply and Traction Company announce a final dividend of 7 per cent., making 10 per cent. for the year.

The directors of Babcock and Wilcox announce a final dividend of 9 per cent. actual, free of tax, making 16 per cent., free of tax, for the year.

The Calcutta Tramways Company last week offered for public subscription £250 000 7 per cent. second (registered) debentures. The issue was heavily over-subscribed within a few hours.

The net profit for the past year of Scarborough Electric Supply Company amounted to £45 after adding £4 000 to depreciation. The sum of £9 817 was brought in. A dividend of 2¼ per cent. is proposed, leaving £7 612 to be carried forward.

The net revenue of Tynemouth and District Electric Traction Company for 1921 amounted to £3 860, plus £8 794 brought in, making £12 654. The directors propose a dividend on the ordinary shares at 10 per cent. for the year, carrying forward £6 488.

The accounts of the Shanghai Electric Construction Co. show that £30 000 has been placed to reserve. A final dividend of 8 per cent. (actual) is recommended, making 20 per cent. for the year. In June last a share bonus of 25 per cent. was distributed out of reserve.

The profit of the Cleveland and Durham Electric Power Company for 1921 was £40 462, making with £5 359 brought in £45 821, of which interest on debentures, etc., absorbed £43 945, leaving £1 876 to be carried forward. The capital expenditure on works during the year amounted to £33 627.

The revenue of the Submarine Cables Trust for the year to April 15, 1922, was £29 958, and expenses £1 983, leaving balance of £27 974, plus £19 brought forward. After providing £7 941 to meet payment of coupons and £546 to be refunded to Inland Revenue, £19 456 has been transferred to redemption fund and £50 carried forward.

The profit for 1921 of Gravesend and Northfleet Electric Tramways Company, after providing £11 576 for repairs, renewals and maintenance and meeting debenture interest, etc., was £400, making available, with £4 944 brought forward, £5 344. £1 000 is placed to reserve (making £10 687), leaving £4 258 to be carried forward.

The net profit of the Havana Electric Railway, Light and Power Company for 1921 amounted to $4 620 064. The sum of $1 923 879 has been placed to reserve, leaving $2 696 185, plus $3 629 099 brought in, making $6 326 084. Dividends paid (6 per cent. on the preferred, and 6 per cent. on the common stock) absorbed $2 155 579, leaving $3 781 041 to be carried forward.

The revenue of Peterborough Electric Traction Company for 1921 from all sources was £29 267, a decrease of £1 466. Expenses, including debenture interest and £3 500 placed to renewals fund (against £3 000), amount to £26 607, a decrease of £328, leaving £2 660, plus £932 brought in, making £3 592. The directors recommend payment of a dividend at 5 per cent. on the ordinary shares, carrying forward £1 272. £571 was expended on capital account. Total capital expenditure amounted to £72 266, compared with shares and debenture stock issued of £63 000.

The accounts of Callender's Cable and Construction Company for 1921 show a credit balance of £217 012. After deducting interest on debenture stock, dividends on preference shares, appropriation for depreciation of buildings, plant and machinery of £30 000 and of office furniture £500, the net profit was £117 012, making with £108 101 brought in £225 113. The directors propose payment of a dividend on the ordinary shares at 15 per cent. per annum, less tax, being 3s. per share, of which 1s. per share has been paid. The sum of £150 113 remains to be carried forward.

An Exchange message states that the report of the Swedish-Danish-Russian Telephone Company, which has a telephone system in Moscow, shows a loss last year, when the company's activities were practically at a standstill, amounting to 1.55 million kroner, of which 1.39 million is directly concerned with the Moscow branch. Since 1917 accumulated losses have reached a total of 5.61 million kroner. The company owns 8 808 of the 9 000 shares of the Cedergren Telephone Company, which last year incurred a loss of 1.41 million kroner, making its total losses since 1916 7.79 million kroner.

The report of the Ever Ready Company (Great Britain) for the year to March 31 last shows, after allowing for various charges, £39 576 available for appropriation. The directors recommend final dividends of 5½ per cent. for the half-year to March 31, 1922, on the preference shares, fully paid, making 9 per cent. for the year, and 9 per cent. on the ordinary shares for the year, carrying forward £5 152. Early in March, 1922, a final settlement was made with the authorities of all taxation up to March 31, 1922 (excepting corporation profits tax, which is reserved for). The sum of £4 922 in suspense in the balance-sheet as at March 31, 1921, was absorbed in the settlement.

The accounts of the Indian Electric Supply and Traction Company for 1921 show surplus on working in Cawnpore of £26 501, against £34 969 in 1920, and including transfer fees and bank interest the credit balance is £30 499. Actual net earnings in India were

Rs4 35.232, as against Rs4 10.222 for 1920, but sterling equivalent is lower owing to the fall in exchange. London expenditure was £2 433, and after providing £2 979 for debenture interest and including £5 075 brought forward there remains £30 162. The board have placed to reserve for depreciation and renewals £7 736, and recommend a final dividend of 7 per cent., making 10 per cent., carrying forward, subject to taxation, £3 197.

The accounts of the Potteries Electric Traction Company for the year ended December 31 last show that the capital expenditure during the year amounted to £12 199, and the revenue to £300 832. The traffic and parcels receipts, which totalled £283 153, exceeded those of last year by £2 521. Expenses increased by £6 562. After deducting all expenses chargeable to revenue, including £11 025 for debenture interest, and a provision of £10 000 for renewals fund, making it £55 891, there remains £27 841 against £28 500 10s. for 1920. Adding £6 082 brought forward there is a balance available for distribution of £33 923, which the directors recommend be applied as follows: To reserve account £5 000 (bringing it up to £114 523), to payment of a dividend on the preference shares at the rate of 5 per cent. per annum £12 250, to payment of a dividend on the ordinary shares at the rate of 4 per cent. per annum £9 800, leaving £6 873 to be carried forward.

Presiding last week at the annual meeting of Pinchin, Johnson, Ltd., Mr. Edward Robson said that, in common with practically every other industry, they had found that the general financial and economic conditions of the world had been so exceptional and, in regard to their foreign trade, so chaotic, that with some of the overseas markets it had been almost impossible to trade. They had, however, maintained their markets in a reasonably satisfactory degree. Their home trade had been extremely satisfactory, and even in some of the most difficult of their export markets they had been able considerably to strengthen and consolidate their position. Their stock in trade at December 31 last showed a very considerable reduction compared with the previous year, and they now appeared to have reached the position that was clearly established in regard to raw material values. It was difficult to predict the future in the present unsettled state of affairs, but their returns to date gave every indication that the extreme slump was more or less at an end, and there were already indications, as far as their particular business was concerned, that a moderate but, he hoped, steady, improvement had set in, and they looked forward to a very satisfactory year of trading in 1922.

Addressing the shareholders at the annual meeting of the Bath Electric Tramways, Ltd., last week, Mr. J. B. Hamilton (the Chairman) first apologised for the late date at which the report and accounts were being presented. The delay, he said, was entirely due to his having had, for health purposes, to take a long rest. This took the form of a journey round the world, and being, if anything at all, a transport man, he had been able to advance his knowledge of what was being done in this respect in other countries. He wished to say that those who had invested their money in tramways in cities of this country need have no fear of such undertakings being superseded by other forms of traction which were very loudly applauded in some of the motor journals. There was not a single example, either in America or throughout the East, of tramways being superseded by any other form of traction in cities. It was quite true that in some places where tramways were unsuitable, owing to great density of traffic, such as prevailed in London, motor buses had been introduced, and that, in districts where the population was too sparse to justify the high initial cost of installing a tramway, other forms of traction had been adopted, such as motor omnibuses or railless electric traction; but in all the cities of the world where the electric tramcar was practically doing the work of transportation it was, in his view, likely to continue to do so for many years to come. An abstract of the accounts appeared in our last issue.

The revenue of the Cork Electric Tramways and Lighting Company for the year 1921 amounted to £114 773. The revenue from the tramways was £1 406 less than for the previous year, due to the strike referred to in the directors' last report. The revenue from lighting and power shows an increase of £6 430 and the profits on supply sales, discounts, etc., a decrease of £1 018; expenses amounted to £98 772. The cost of generating was £1 593 less than for 1920, due to the fall towards the end of the year in the price of coal. There were increases of (*a*) £687 in the cost of maintaining and operating the tramways, (*b*) £1 841 in the lighting and power distribution expenses, (*c*) £2 576 in insurances, management, and other general expenses, and (*d*) £293 in bad debts. The gross profit for the year was £16 001 to which is added £5 702 carried forward from 1920, and after meeting income tax and interest charges and transferring to reserve for depreciation and renewals £12 000 (compared with £6 500) there is a balance to carry forward of £2 800. The capital expenditure during the year amounted to £35 031. This mainly covers the installation of a 2 000 kW Curtis turbine and other plant at the Cork generating station, additional cables and house services to meet the increasing demand for lighting and power, and new plant at the Queenstown generating station which has been installed in order to reduce the cost of generating. The revenue to date shows an increase over the corresponding period of last year and enables the company to pay a half-year's dividend on the 5 per cent. cumulative preference share capital. This payment will clear the arrears to June 30, 1920.

New Companies.

George McCombe and Company.

George McCombe and Company, Ltd. (18 200.) Private company. Reg. in Edinburgh May 4. Capital, £2 500 in 2 300 preference shares and 200 ordinary of £1 each. Motor, steam and electrical engineers, etc. Subscribers: J. K. MacDonald, R. Cunningham.

Superadio, Ltd.

Superadio, Ltd. (181 747).—Private company. Reg. May 12. Capital, £1 000 in £1 shares. Manufacturers, exporters and importers of, and dealers in wireless telegraphic and telephonic appliances, installations, goods and accessories of all kinds, electrical lighting goods, &c. Subscribers: C. Orgel and S. Orgel. Registered office: 111, Great Eastern Street, E.C.

Newcastleton Electric Supply Company.

Newcastleton Electric Supply Company, Ltd. (12 204). Private company. Reg. in Edinburgh, May 9. Capital, £1 000 in £1 shares. To carry on business as indicated by the title. First directors: Miss Agnes Scott, C. Wood, T. Martin, T. J. Ewart, T. Oliver, A. Oliver, R. Wilson, J. Davidson, D. Oliver and J. Carruthers. Registered office, 44A, South Hermitage Street, Newcastleton.

Tylor Engineering Company.

Tylor Engineering Company, Ltd. (181 672). Private company. Reg. May 9. Capital, £120 000 in £1 shares. To acquire the business carried on by J. Tylor and Sons, Ltd., and to trade as mechanical, consulting, hydraulic, electrical engineers, manufacturers of electrical plant and apparatus, etc. Subscribers: A. J. Fletcher, H. E. Herrick. Solicitors: Collisson, Prichard and Barnes, 27, Bedford Row, W.C.1.

Illuminated Identification Number Plate Company, Ltd.

Illuminated Identification Number Plate Company, Ltd. (181 688.) Private company. Reg. May 10. Capital, £500 in £1 shares. Manufacturers and sellers of parts and apparatus of all kinds for lighting, illuminating and heating; contractors, general engineers; manufacturers of and dealers in lamps, lanterns, etc. Subscribers: D. A. Ellam, H. Robinson, N. R. Spencer. Registered office: 10, Raglan-street, Halifax.

Magneto Repair and Winding Company.

Magneto Repair and Winding Company, Ltd. (181 658.) Private company. Reg. May 9. Capital, £500 in £1 shares. To take over the business of magneto repairing and electrical engineering carried on by D. Jones at 5, Salubrious Place, Swansea, as the "Magneto Winding and Repairing Company." Provisional directors: D. Jones, F. H. Thomas. Secretary: D. Jones. Registered office: 5, Salubrious Place, Swansea.

French Mutagraph Company.

French Mutagraph Co., Ltd. (171 646.) Private company. Reg. May 9. Capital, £5 000 in 4 500 preference shares of £1 each and 10 000 deferred shares of 1s. each. To adopt an agreement with L. E. Falcy, and to carry on the business of advertising sign manufacturers, mechanical and electrical engineers, etc. First directors: L. E. Falcy and H. L. Dixon. Qualification: £100. Registered office: 14, Bedford Row, W. C.

Acme Production Company.

Acme Production Company, Ltd. (181 752).—Private company. Reg. May 12. Capital, £3 000 in £1 shares. To acquire the business of manufacturers of and dealers in electrical and mechanical appliances and scientific instruments now carried on by W. J. Allen and W. D. Vick at 73½, Coleshill Street, Birmingham. Permanent directors: W. J. Allen, W. D. Vick, and W. H. Fulford. Registered office: 73½, Coleshill Street, Birmingham.

The Wayne Engineering and Equipment Company.

The Wayne Engineering and Equipment Company has opened the following branch offices: The Efandem Company, Ltd., 28, Queen-street, Albert-square, Manchester; Astbury and Madeley, Empire House, Great Charles-street, Birmingham; W. Anderson Penman, 36, Exchange-street, Norwich; G. F. French, Kent Works, Kendal; Douglas G. Cochrane and Co., Ltd., Princes-buildings, 11, Akenside-hill, Newcastle-on-Tyne; Philip and Bruce, Ltd., 50, Wellington-street, Glasgow.

H. R. Gear.

H. R. Gear Co., Ltd. (181 590). Private company. Reg. May 6. Capital, £5 000 in £1 shares. To acquire from E. C. Hatcher and T. Rooke, the benefit of certain existing inventions relating to reduction gears, and to carry on the business of engineers and contractors, manufacturers of and dealers in railway, tramway, electrical, magnetic, galvanic and other apparatus, etc. First directors: Major E. C. Hatcher, T. Rooke, H. C. B. Underdown, G. E. Marten. Solicitors: Kimbers, Williams and Co., 79, Lombard-street, E.C.

Park Electrical and Engineering.

Park Electrical and Engineering Co., Ltd. (181 622). Private company. Reg. May 8. Capital, £10 000 in £1 shares. To acquire the land and building in Ashburton Road, Trafford Park, Manchester, and now owned by the Park Electrical and

Engineering Co., and to carry on the business of electrical and mechanical engineers, electricians, and manufacturers, etc. Permanent directors: G. L. Brown, A. C. Penny. Secretary: G. L. Brown. Solicitor: J. Prior, 438, Corn Exchange-buildings, Manchester.

Wholesale Electrical Company.

WHOLESALE ELECTRICAL CO. (1922), LTD. (181 757).—Reg. May 12. Capital, £20 500 in 20 000 cumulative 10 per cent participating preference shares of £1 each and 10 000 ordinary shares of 1s. each. To adopt an agreement with A. W. Little, and to carry on the business of electrical and mechanical engineers, manufacturers of electrical equipment, &c. First directors: A. W. Little (chairman), N. E. Rutherdon, and T. W. Greaves. Registered office: 5, Guildhall Chambers, 31-4, Basinghall Street, E.C.2.

Sir Charles Bright and Partners.

SIR CHARLES BRIGHT AND PARTNERS, LTD. Reg. May 10. Private company. Nominal capital, £2 000 in £1 shares. To adopt an agreement with Sir Charles Bright and Partners, and to carry on the business of advising, inspecting, consulting and superintending engineers, electrical (including telegraph, telephone and submarine cable) engineers, etc. Permanent directors: Sir Charles Bright, A. H. Seabrook, A. J. Stubbs, Lieut.-Col. H. W. Wordall. Secretary: A. J. Stubbs. Registered office: 146, Bishopsgate, E.C. File number, 181 695.

Electrical Imports and Exports.

IMPORTS.—The following are official values of electrical machinery, apparatus and material imported into this country (*a*) during April, 1922, and (*b*) the aggregate figures from January 1 to April 30, with increase or decrease compared with corresponding periods of 1921 :—

Electrical machinery, (*a*) £68 967 (increase £16 810), (*b*) £450 512 (increase £151 439); telegraph and telephone cables, submarine, nil; other than submarine, (*a*) £1 241 (decrease £9 364), (*b*) £12 156 (decrease £26 188); telegraph and telephone apparatus, (*a*) £12 323 (decrease £24 705), (*b*) £51 610 (decrease £73 850); other electrical wires and cables, rubber insulated, (*a*) £18 023 (increase £15 170), (*b*) £37 384 (increase £26 762); with other insulations, (*a*) £2 445 (decrease £1 857), (*b*) £18 954 (decrease £24 045); carbons, (*a*) £1 609 (decrease £6 304), (*b*) £11 899 (decrease £29 085); glow lamps, (*a*) £10 435 (decrease £27 614), (*b*) £63 145 (decrease £37 578); arc lamps and electrical searchlights, (*a*) £15 (decrease £829), (*b*) £65 (decrease £5 570); parts of arc lamps and searchlights (other than carbons), (*a*) £1 383 (increase £484), (*b*) £3 552 (decrease £2 500); batteries, (*a*) £6 233 (decrease £3 447), (*b*) £21 918 (decrease £37 600); electrical instruments, commercial, scientific and electricity meters, (*a*) £4 683 (decrease £12 238), (*b*) £19 000 (decrease £66 060); switchboards, (*a*) £140 (increase £34), (*b*) £1 519 (increase £243); other electrical goods and apparatus, (*a*) £42 000 (decrease £39 803), (*b*) £175 990 (decrease £203 627). Total of electrical machinery, apparatus and material (other than uninsulated wire), (*a*) £169 497 (decrease £93 663), (*b*) £867 704 (decrease £327 659).

EXPORTS.—The exports of electrical machinery, apparatus and material (*a*) during April, 1922, and (*b*) from January 1 to April 30, with increase or decrease compared with corresponding periods of 1921, were as follows :—

Electrical machinery, (*a*) £450 489 (increase £27 732), (*b*) £1 886 883 (increase £209 315); including railway and tramway motors, (*a*) £5 098 (decrease £22 323), (*b*) £58 708 (decrease £23 868); other generators and motors, (*a*) £202 263 (decrease £16 797), (*b*) £1 001 453 (increase £74 110); and other electrical machinery, (*a*) £243 128 (increase £66 862), (*b*) £826 722 (increase £159 070); telegraph and telephone cables, submarine, (*a*) £23 020 (decrease £364 929), (*b*) £105 271 (decrease £569 610); other than submarine, (*a*) £61 813 (decrease £65 268), (*b*) £207 549 (decrease £400 305); telegraph and telephone apparatus, (*a*) £166 909 (increase £36 229), (*b*) £707 978 (increase £131 657); other electrical wires and cables, rubber insulated (*a*) £49 931 (decrease £112 983), (*b*) £195 504 (decrease £461 073); with other insulations, (*a*) £83 567 (decrease £146 157), (*b*) £421 026 (decrease £419 284); carbons, (*a*) £2 850 (decrease £328), (*b*) £15 458 (decrease £28 178); glow lamps, (*a*) £39 178 (decrease £14 321), (*b*) £136 120 (decrease £55 522); arc lamps and searchlights, (*a*) £409 (decrease £737), (*b*) £3 254 (decrease £722); parts of arc lamps and searchlights (other than carbons), (*a*) £546 (decrease £460), (*b*) £1 938 (decrease £1 085); batteries, (*a*) £41 990 (decrease £32 446), (*b*) £147 903 (decrease £144 009); electrical instruments, commercial and scientific and electricity meters, (*a*) £28 547 (decrease £14 905), (*b*) £134 488 (decrease £27 177); switchboards, (*a*) £13 185 (decrease £9 322), (*b*) £139 050 (increase £70 483); other electrical goods and apparatus, (*a*) £82 146 (decrease £116 391), (*b*) £418 995 (decrease £483 167). Total of electrical machinery, material and apparatus, other than uninsulated wire, (*a*) £1 044 580 (decrease £814 286), (*b*) £4 521 417 (decrease £2 166 677).

FAVERSHAM Corporation has received a protest from the A.M.E.E. against the reduction of the salary of the electrical engineer (Mr. G. S. Somerville) to £396 per annum; but at last week's meeting the Council decided to adhere to the decision to make the reduction.

Tenders Invited and Accepted.

UNITED KINGDOM.

BELFAST TRAMWAYS COMMITTEE. May 19.—Four junctions and 12 crossovers; also reconstruction of 10 miles, or alternatively $3\frac{5}{8}$ miles of single track. Specifications from General Manager

COUNTY BOROUGH OF WEST BROMWICH. MAY 22.—Supply of the following in connection with the reconstruction of the tramways: (1) Rail, fish plates, &c.; (2) tie bars, bolts, &c.; (3) points, crossings and special work; (4) copper bonds. Particulars from Mr. A. D. Greatorex, Borough Engineer and Surveyor, Town Hall, West Bromwich.

CHESHIRE LINES COMMITTEE. May 30.—Six months' supply of stores, including telegraph materials, iron tubing, oils, paints, &c. Specification from the Stores Superintendent, Cheshire Lines, Warrington.

GREAT NORTH OF SCOTLAND RAILWAY COMPANY. May 30.—Telegraph material, castings, ironmongery, rubber goods, &c. Forms of tender from the Stores Superintendent, 80, Guild-street, Aberdeen.

LAMBETH GUARDIANS. May 30.—Wiring and fitting of Lambeth Hospital. Particulars from the Clerk, Guardians' Offices, Brook Street, Kennington Road, S.E.11.

NOTTINGHAM ELECTRICITY COMMITTEE. June 1.—General stores for the electricity department for six or twelve months. Forms of tender from the Electrical Engineer, Electricity Station, Talbot Street, Nottingham.

ISLINGTON GUARDIANS. June 15.—Installing electric light and power equipment at St. John's Road Institution, Guardians' Offices, and Relief Offices. Particulars from Messrs. Wallis Jones & Dent, Consulting Electrical Engineers, 23, Old Queen Street, Westminster, London, S.W.1.

DUBLIN COUNTY COUNCIL.—Tenders for the removal of the old, and installation of a new system of inter-communicating house telephones. Particulars from Mr. H. J. Clancy, Secretary, Dublin County Council, 11, Parnell Square, Dublin.

BELGIUM.

MUNICIPALITY OF SAINT GILLES (BRUSSELS). MAY 23.*—Supply of (1) About 4 000 metres of armoured cable of 3 by 50 mm.²: for three-phase current at 5 000 V. between phases, 50 cycles; (2) about 2 000 metres of armoured telephone cable of 2 by 1 mm.²; (3) all the necessary accessories for the above.

INDIA.

HIGH COMMISSIONER OF INDIA, June 9.—Supply of copper telegraph wire, Carsack elements for Leclanche cells, V.I.R. cable. Particulars from the Director-General, India Store Department, Belvedere Road, Lambeth, S.E.1.

AUSTRALIA.

COMMONWEALTH OF AUSTRALIA. June 20.—426½ tons bronze wire (Schedule 28), 400 tons galvanised iron wire (Schedule 32), 47 tons galvanised steel wire (Schedule 32), 313 400 jointing sleeves (Schedule 33). Particulars from Supply Officer, Room 101, Australia House, Strand, W.C.

VICTORIAN ELECTRICITY COMMISSION. September 1.—Five surface-feed water heaters, six surface vapour condensers, and twelve feed-water evaporators. Specifications from the Agent-General for Victoria, Melbourne-place, Strand, London, W.C.2.

SOUTH AMERICA.

ARGENTINE BOARD OF SANITARY WORKS. JUNE 28.*—Construction and erection of equipment for a hydro-electric generating station and transforming sub-station for the town of Catamarca, Province of Catamarca.

BUENOS AIRES WATERWORKS.*—Machinery for three pumping stations, one power station, and eight transforming sub-stations.

SOUTH AFRICA.

MUNICIPAL AUTHORITIES OF THE CITY OF GRAHAMSTOWN. September 1.*—Complete Lighting scheme for the city.

CHEADLE Urban Council have accepted the tender of the Macintosh Cable Company for cable at £18 737.

BRIDGEND Corporation have accepted the tender of W. H. Allen, Son & Company for a two-phase turbo-alternator at £3 445.

The tender of G. H. Blackburn has been accepted for electrical equipment for a new cinema in St. George's-road BOLTON.

BRADFORD Tramways Committee have accepted the tender of Hadfields, Ltd., for 12 pairs of manganese steel points at £101 per pair.

BOLTON Tramways Committee have accepted the tender of the General Electric Company for e.h.p. switch gear for Bradshawgate sub-station.

LONDON County Council have accepted the tenders of A. Hawkins & Sons for electric wiring, &c., in Belleville Road (Battersea) schools at £718 10s., and Wormholt Road (Hammersmith) schools at £718 15s.

PORTSMOUTH Town Council has accepted the following tenders :—Pirelli General Cable Works, Ltd., cables at £483 10s.; Johnson and Phillips, Ltd., cable, £52 10s.; G. and J. Weir, Ltd., circulating pump, £970, and three feed pumps, £185 each.

* Particulars from the Department of Overseas Trade.

COMMERCIAL INTELLIGENCE.

Deeds of Arrangement.

WYNESS, Thomas Reginald Watt, and BALE, George Wilfred, trading at 13, Commercial Street, Brighouse, as WYNESS & BALE, electrical engineers. Filed May 10, by order on terms. Trustee, H. S. Dickinson, 30, Huddersfield Road, Brighouse. Secured creditors, £726; liabilities unsecured, £2 704; assets, less secured claims, £1 656. The following are creditors:—W. T. Henley's Telegraph Works, London, £199; English Electric & Siemens, Ltd., London, £157; Berry's Electric Company, Ltd., London, £34; Metallic Eng. Company, Birmingham, £76; Simplex Conduits, Ltd., Birmingham, £63; Donovan & Company, Birmingham, £109; Hirst, J. A., Brighouse, £150; Albion Electric Stores, Leeds, £31; General Electric Company, Leeds, £253; Wholesale Fittings Company, Manchester, £31; Beardsell & Company, Manchester, £47; Edison & Swan, Ltd., Ponders End, £59; British Insulated & Helsby Cables, Ltd., Prescot, £56; St. Helen's Cable & Rubber Company, St. Helen's, £88; Walsall Hardware Company, Walsall, £190; Siemen Bros. & Company, Woolwich, £47.

JONES, Herbert Henry, electrical engineer, trading as the STANDARD ELECTRICAL COMPANY, 4, Dillwyn Street, Swansea, electrical engineers' merchant. Filed May 11. Trustee, C. H. Harvey, 3, Goat Street, Swansea. Secured creditors, £293; liabilities unsecured, £1 773; assets, less secured claims, £1 448.

RECEIVERSHIP.

REMCO CARBON COMPANY, LTD.—R. Crane, of 46 and 47, London-wall, E.C., was appointed Receiver on March 1, under powers contained in debentures dated November 29, 1918.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

AIREDALE ELECTRICAL & MANUFACTURING COMPANY, LTD., Bradford. Registered May 2, £350; general charge, *£525. March 14, 1922.

BODMIN ELECTRIC LIGHT & SUPPLY COMPANY, LTD. Registered May 4, £100 debentures, balance of £2 000; general charge. *Nil. February 21, 1922.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Companies Winding-up Voluntarily.

AQUA ELECTRIC COMPANY, LTD. C. H. McKnight, 36, New Broad Street, E.C.2, appointed liquidator. Meeting of creditors at the Chartered Institute of Secretaries, 59a, London Wall, London, E.C.2, Monday, May 29, at 2.30 p.m. Particulars of claims to the liquidator by July 10.

BETA BATTERIES, LTD. J. A. Cameron, 5, New Court, Lincoln's Inn, London, W.C.2, appointed liquidator. Meeting of creditors at the liquidator's office, Friday, May 26, at 11 a.m. Particulars of claims to the liquidator by June 17.

PARK BROTHERS, LTD.—W. A. J. Osborne, Balfour House, Finsbury-pavement, London, E.C., appointed liquidator. Meeting of creditors at the liquidator's office, May 19, at 12 noon. Particulars of claims to the liquidator by June 23.

Bankruptcy Information.

CARTER, Thomas, 2, South Street, Dorchester, and at High Street, Swanage, Dorset, electrical engineer. Receiving order, May 11. Creditor's petition.

GIBBONS, Albert Ralph, 8, The Parade, New Eltham, Kent, electrical engineer. Receiving order, May 9. Creditor's petition. First meeting, May 22, 12 noon, 29, Russell-square, W.C.1. Public examination, June 20, 11 a.m., Court House, Greenwich.

HILL, George, NOBLE, George, and COWLEY, Edgar, in co-partnership as GEORGE HILL & COMPANY, 22, Chantry-lane, Great Grimsby, electrical engineers. Receiving order, May 6. Debtor's petition. First meeting, May 20, 11 a.m., Official Receiver's office, St. Mary's Chambers, Great Grimsby. Public examination, June 1, 11 a.m., Town Hall, Great Grimsby.

MAGSON, Reginald Silver, 10, Stoney Stanton Road, Coventry, as R. S. MAGSON & COMPANY, electrical engineer. Receiving order, May 11. Debtor's petition.

RIDGWAY, Fred, and TYNAN, Thomas, in co-partnership at 21, Bowling Old-lane, Bradford, under the style of RIDGWAY & TYNAN, electrical engineers. Receiving order, May 8. Debtor's petition. First meeting, May 19, 3.30 p.m., 12, Duke-street, Bradford. Public examination, May 24, 10 a.m., County Court, Manor-row, Bradford.

RIMMER, William Frederick, 21, Ellesmere-street, Patricroft, co. Lancaster, electrical engineer. First meeting, May 23, 2.30 p.m., Official Receiver's office, Byrom-street, Manchester. Public examination, June 15, 10.30 a.m., Court House, Encombe-place, Salford.

Application for Discharge.

HOPKINS, John Howard, formerly trading as THE ELECTRICAL MAINTENANCE COMPANY, 57, Castellaine Mansions, Maida Vale, lately at 140, Wardour Street, London. Hearing, June 16, 11 a.m., Bankruptcy Buildings, Carey Street, London, W.C.2.

Notices of Dividends.

DAVIS, William Aaron, late 3, Coronation-street, now 14, Basinghall-street, Leeds, electrical engineer. Amount per £, 2⅛d. First and final. Payable, May 25, 24, Bond-street, Leeds.

OWEN, Joseph (trading as J. OWEN & SONS), 186, Westcombe-hill, Greenwich, and 3, The Grove, Greenwich, electrical engineer. Amount per £, 2s. 3d. First. Payable, May 30, 29, Russell-square, W.C.1.

WOLLMAN, Harry Michael, late 9, Greasbro'-road, Parkgate, Rotherham, co. York, electrical factor. Amount per £, 4s. 4¼d., first and final. Payable, May 17, 14, Figtree-lane, Sheffield.

Order Made on Application to Approve Scheme.

ROTHWELL, Peter, 13, Hampden-street, Bolton, trading with P. A. Rothwell (a minor) as P. A. Rothwell & Company, 64, Higher Bridge-street, Bolton, electrical engineer. Order made, April 12. Composition of 7s. in the £ to all unsecured creditors. Receiving order discharged.

DUBLIN GAZETTE.

PORTARLINGTON ELECTRIC LIGHT AND POWER COMPANY, LTD. Particulars of claims by June 22, to Michael Crowley, 16, College-green, Dublin, the liquidator.

Catalogues, Price Lists, &c.

Details of the HILGER CHEMICAL SPECTROMETER are given in an illustrated leaflet just issued by the firm.

The advantages of intercommunication telephones are attractively set forth in a leaflet on the subject lately published by the RELIANCE TELEPHONE COMPANY.

A "HANDBOOK ON CONTROLLERS FOR ELECTRIC MOTORS" has lately been published by the Electric Power Club, St. Louis, U.S.A., and contains a simple description of controllers and definitions of the terms used in connection with them.

The Shurvent renewable fuse, recently developed by the WESTINGHOUSE ELECTRIC and Manufacturing Company, of East Pittsburgh, Pa., is described in detail in Folder 4 472, entitled "Shurvent Protection," which has just been published by the company.

The quarterly bulletin (No. 94) of A.C.E.C. (ATELIERS DE CONSTRUCTIONS ELECTRIQUES DE CHARLEROI) is to hand, and contains further particulars regarding the effects of the German occupation of the company's works. Interesting articles on electric winding engines, high lift centrifugal pumps and condensers for power factor improvement, etc., are also given.

An excellent photograph of the machine, fitting, and winding shop at the Albert Works of GREEN & SMITH, LTD., is shown on a leaflet just issued by the firm. The shop is fitted with a 3-ton travelling crane, modern machine tools and drying oven for stators, armatures, etc. Another leaflet shows, after repair, a 500 V d.c. coal cutter armature, which was sent to the firm with a broken shaft and loose core.

WATSON & SONS (ELECTRO-MEDICAL), LTD., are circulating several new publications. The "Sunic" ionostat, a new instrument for galvanization, ionization, electrolysis, illumination of surgical lamps, etc., is fully described in Bulletin 43 S., which also contains particulars of various instruments for electrolysis, etc. Bulletin 45 S. deals with the radiological i nometer and other instruments for measuring X-ray dosage; and in Bulletin 46 S. waterproof surface "Sunic" intensifying screens are described.

Arrangements for the Week.

FRIDAY, MAY 19th (to-day).

INSTITUTION OF ELECTRICAL ENGINEERS.
(LONDON STUDENTS' SECTION.)

7 *p.m.* At Savoy-place, London, W.C.2. "The Elimination of Atmospherics in Radio-Telegraphy," by Mr. A. H. Reeves.

SATURDAY, MAY 20th.

ROYAL INSTITUTION OF GREAT BRITAIN.

3 *p.m.* At Albemarle-street, Piccadilly, London, W.1. Lecture on "The Disappearing Gap between the X-ray and Ultra-Violet Spectra (II) Photo-Electric Methods," by Prof. O. W. Richardson, D.Sc., F.R.S.

WEDNESDAY, MAY 24th.

ROYAL SOCIETY OF ARTS.

8 *p.m.* At John-street, Adelphi, London. "The Natural Power Resources of Ireland (Coal, Peat, Water Power)," by Mr. George Fletcher.

THURSDAY, MAY 25th.

INSTITUTION OF ELECTRICAL ENGINEERS.

6 *p.m.* At Savoy-place, London, W.C.2. Annual General Meeting.

ILLUMINATING ENGINEERING SOCIETY.

8 *p.m.* At Royal Society of Arts, John-street, Adelphi, London. Annual Meeting. Presidential Address by Sir J. H. Parsons, C.B.E., F.R.S.

FRIDAY, MAY 26th.

PHYSICAL SOCIETY OF LONDON.

5 *p.m.* At the Imperial College of Science, South Kensington, London. Lecture on "Atomic Weights and Isotopes," by Dr. F. W. Aston, F.R.S.

JUNIOR INSTITUTION OF ENGINEERS.

8 *p.m.* At Caxton Hall, London, S.W. "Engineering Appointments and How to Get Them," by Mr. J. Cameron Rennie.

ROYAL INSTITUTION OF GREAT BRITAIN.

9 *p.m.* At 21, Albemarle-street, London, W.1. "The Internal Combustion Engine: Its Influence and its Problems," by Mr. W. E. Dalby, B.Sc., F.R.S.

Prices of Metals, Chemicals, etc.

TUESDAY, MAY 16.

		Price.	Inc.	Dec.
Copper—				
Best Selected ..	per ton	£63 10 0	—	5s.
Electro Wirebars ..	,,	£68 0 0	£1	—
H.C. Wire, basis ..	per lb.	os. $10\frac{1}{16}$d.	$\frac{1}{8}$d.	—
Sheet	,,	os. $9\frac{7}{16}$d.	—	—
Phosphor Bronze Wire (Telephone)—				
Phosphor Bronze Wire, basis ..	per lb.	1s. $2\frac{1}{16}$d.	$\frac{1}{8}$d.	—
Brass 60/40—				
Rod, basis ..	,,	7d.	—	—
Sheet, basis ..	,,	$8\frac{3}{4}$d.	—	—
Wire, basis ..	,,	$9\frac{3}{4}$d.	—	—
Pig Iron—				
Cleveland Warrants	per ton	£4 15 0	—	—
Galvanised steel wire, basis 8 S.W.G.	,,	£18 0 0	—	—
Lead Pig—				
English	,,	£25 5 0	—	5s.
Foreign or Colonial	,,	£24 0 0	—	7s. 6d.
Tin—				
Ingot	,,	£149 10 0	—	—
Wire, basis ..	per lb.	2s. $0\frac{5}{8}$d.	—	$\frac{1}{8}$d.
Aluminium Ingots ..	per ton	£100 0 0	—	£20
Spelter	,,	£27 0 0	—	2s. 6d.
Mercury	per bottle	£11 0 0	—	—

Sulphur (Flowers)—Ton £10 15s. *Sodium Chlorate*—Per lb. $3\frac{1}{4}$d.
,, (Roll-Brimstone)—per ton £10 15s. *Sulphuric Acid* (Pyrites, 168°) per ton, £9.
Sodium Bichromate.—Per lb. $5\frac{1}{4}$d. *Copper Sulphate*.—Per ton £26 10s.
Boric Acid (Crystals). Per ton £60.
Rubber.—Para fine, $10\frac{1}{2}$d.; plantation 1st latex, $8\frac{1}{8}$d.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd., and the rubber prices by W. T. Henley's Telegraph Works Company.

The TELEPHONE SERVICE IN FRANCE appears to be so bad that many deputies are urging the Government to hand over the business to a private company for development. The inefficient service is said to be the cause of the limited use made of the telephone in France, where there is only one instrument for each 143 of the inhabitants, compared with 1 in 64 in England, 1 in 59 in Germany and 1 in 8 in the United States. The demand for an improvement of the service and an extension of telephone facilities is growing in volume and intensity, notwithstanding certain allocations for equipping new exchanges and for erecting additional trunk lines.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by MESSRS. MEWBURN, ELLIS & CO., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

COMPLETE SPECIFICATIONS.

143 250 MAREK, A. Process and apparatus for coating articles by electro-plating and heat treatment. (10/10/17.)
171 423 SIEMENS BROS. & CO., LTD., PETITHORY, E. A., & COLLYER, J. E. Selecting devices for automatic telephone systems. (18/5/20.)
145 406 GOUSSET, G. B. Collectors for magnetos used with four-cylinder internal combustion engines. (20/6/19.)
171 430 GREENHALGH, E., & ELECTROMOTORS, LTD. Dynamo-electric machines. (5/7/20.)
146 492 ZÖLLER, A., & FISCHER, G. Electric lamps. (7/11/13).
147 441 GES. FUR DRAHTLOSE TELEGRAPHIE. Electronic tubes. (23/1/18.)
147 463 SCHRÖTER, F. Electric discharge tubes for coupling electric circuits. (9/2/15.)
147 466 SOC. FRANCAISE RADIO ELECTRIQUE. Electro-magnetic wave-receiving systems. (7/5/19.)
147 777 APPLE, V. G. Construction of armatures for dynamo-electric machines. (29/1/17.)
147 778 APPLE, V. G. Armature construction for dynamo-electric machines. (19/11/14.)
148 229 ADERT, L. (formerly ADAMCZAK, L.). Driving system for alternating current meters on the Ferraris principle. (14/1/19.)
148 368 KÖHLER CO. Electric generating systems. (20/3/19).
148 985 SIGNAL GES. Acoustical improvements in electro-magnetic sound producers and receivers. (20/1/19.) (Addition to 148 976.)
171 433 SIEMENS BROS. & CO., LTD., & CHRISTIAN, D. A. Automatic and semi-automatic telephone systems. (12/7/20.)
149 192 HUTH GES., DR. E. F., & HELLER, W. Method for generating and amplifying oscillations of any frequency, especially for wireless telegraphy. (17/7/18.)
149 194 HUTH GES., DR. E. F., & ROSENBAUM, B. Arrangement for wireless telegraphy from submarines. (8/12/16.)
149 272 FOREST, L. DE. Radio-signalling systems. (10/5/15).
154 914 LUFTFAHRZEUGBAU SCHUTTE-LANZ. Electro-magnet for locking devices. (9/12/16.)
151 245 ADERT, L. (formerly ADAMCZAK, A.). Driving system for alternating current meters on the Ferraris principle. (31/12/18.)
152 316 ALLGEMEINE ELEKTRICITATS-GES. Safety switch for installation systems and for windings of electrical machines and apparatus. (6/10/13.)
151 972 ALLGEMEINE ELEKTRICITATS-GES. Coin-freed meter for electric current, gas, water, or the like. (19/9/14.)
151 973 ALLGEMEINE ELEKTRICITATS-GES. Coin-freed meter for electric current, gas, water, or the like. (4/7/17).
171 441 DUCOUSSO, T. Driving electro mechanism for operating rail-track apparatus. (15/7/20.)
171 442 BRITISH THOMSON-HOUSTON CO., LTD. (GENERAL ELECTRIC CO.). Apparatus for electric arc welding. (16/7/20.)
171 451 CLARK, W., & CLARK'S NEO-ELECTRIC DEVICES, LTD. Electrical resistances. (9/8/20.)
171 453 TAGGART, J. SCOTT-, & RADIO COMMUNICATION CO., LTD. Modulation systems and the like in radio-communication and the like. (10/9/20.)
171 458 RAILING, A. H., & ANGOLD, A. E. Electric arc lamps. (11/8/20.)
171 463 SMITH, F. P., & WILSON, T. F. Safety-lock electric switches. (12/8/20)
171 470 WESTERN ELECTRIC CO., LTD. (WESTERN ELECTRIC CO., INC.). Method and means for determining the transmission equivalent of an electrical circuit. (13/8/20.)
171 481 SULLIVAN, H. W., & JOSEPH, J. Variable electrical condensers. (16/8/20.)
171 484 BRITISH THOMSON-HOUSTON CO., LTD. (GENERAL ELECTRIC CO.). Electric switches. (17/8/20.)
171 494 MAURI, D. Three-phase electric furnaces. (19/8/20).
171 497 MILLER, C. A., MILLER, F. J., & SANDERS, E. A. Switch and fuse-holder units for use in electric car-lighting systems. (21/8/20.)
171 498 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD., & MERCER, R. Circuit arrangements for controlling automatic selector-switches. (21/8/20.)
171 502 SEWARD, G. O. Electrolytic apparatus. (23/8/20.)
171 517 LEPINEY, L. A. Incandescent electric lamps. (1/9/20.)
171 520 RADIO COMMUNICATION CO., LTD., & LEA, N. Production of and modulation of electrical oscillations by means of thermionic valves. (2/9/20.)
171 523 SIEMENS BROS. & CO., LTD., PETITHORY, E. A., & COLLYER, J. E. Number-dials for automatic and semi-automatic telephone systems. (3/9/20.)
171 544 HAMMONDS, A. C., & WAGG, M. J. Electric cooking appliances. (8/9/20.)
171 547 REMUS, S. Sparking-plugs for internal combustion engines. (9/9/20.)
171 553 RICHARDS, F. H. Electric ignition in internal combustion engines. (10/9/20.)
171 554 TAYLOR, A. M. Electric power transmission. (11/9/20.) (Patent of addition not granted.)
156 076 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD. Electro-magnetic relays. (31/12/19).
171 578 WATKINSON, J. Electric switches. (5/10/20.)
171 579 CRABTREE, J. A. Electric switches. (6/10/20.) (Addition to 140 180.)
171 581 PAINTER, F., & IDGE, G. H. Electric switches. (7/10/20).
154 931 HOFFMAN, O. Electric pocket lamps. (4/11/19.)
160 456 LATOUR, M. Thermionic valves. (18/3/20.)
170 893 REES, H. P. Tuning instruments for use in wireless telegraphy and telephony. (20/1/21.)
170 901 MARSOLLIER, C. J. Electrical connecting devices and lamp-holders. (29/6/20.) (Addition to 145 587.)
170 902 SMITH, E. A. LAYTON-. Magnetos for ignition purposes. (30/6/20.)
170 915 RAILING, A. H., GARRARD, C. C., & WILSON, W. Balanced electrical relays. (27/7/20.)
170 941 ROUND, H. J. Reception of wireless signals. (30/7/20.)
170 946 NOBUHARA, K. Cooling of dynamo-electric machines. (31/7/20.)
170 953 MACRORIE, A. K., AIREY, H. MORRIS-, & MULLARD, S. R. Thermionic valves. (3/8/20.)
170 954 MACRORIE, A. K., GOLDUP, T. E., & MULLARD, S. R. Thermionic valves. (3/8/20.)
170 955 MACRORIE, A. K., AIREY, H. MORRIS-, SHEARING, G., & MULLARD, S. R. Thermionic valves. (3/8/20.)
170 961 BRITISH THOMSON-HOUSTON CO., LTD., YOUNG, A. P., & WARREN, H. W. H. Magneto-electric machines. (4/8/20.)
170 965 GLASER, W. H., & GLASER, LTD., W. H. Combined electric rectifying and motive-power producing apparatus (4/8/20.)
170 980 BERNARD, P. J. H. Process of manufacturing electric insulators. (18/8/20.)
170 984 BRITISH THOMSON-HOUSTON CO., LTD. (General Electric Co.). Electric motor control. (20/8/20.)
170 989 VANDERVELL, C. A., & VANDERVELL & CO., LTD., C. A. Electrically-driven air compressors. (24/8/20.)
171 003 DAVEY, J. A., & ELECTRO METALS, LTD. Operating the electrodes of electric furnaces. (9/9/20.)
171 009 BRITISH THOMSON-HOUSTON CO., LTD. (General Electric Co.). Electric distribution systems. (16/9/20.)
171 019 LOFTS, G. H. Alloy for use in electric heating appliances. (28/9/20.)
171 129 HASTINGS, R. C. M. Telephonic call systems. (10/6/20.)
171 133 RAILING, M. J., & TAYLOR, T. Electric conduit boxes. (2/7/20.)
171 137 BELLINGER, H. R. Sparking-plugs. (7/7/20.)
171 145 BRITISH THOMSON-HOUSTON CO., LTD., & YOUNG, A. P. Magneto electric machines. (3/8/20.)

171 157 Smith, F. S. Process of and apparatus for electrically treating foods and like products. (6/8/20.)
171 161 Sullivan, H. W. Submarine and other electrical cables. (7/8/20.) (Cognate Application, 14 079/21.)
171 180 British Thomson-Houston Co., Ltd., & Martin, J. Systems of electric ship propulsion. (11/8/20.)
171 183 Macrorie, A. K., & Airey, H. Morris-. Transmitting and receiving circuits for wireless telegraphy. (11/8/20.)
171 194 Hoover Suction Sweeper Co., Ltd. (Hoover, H. E.). Electric motors. (17/8/20.)
171 207 Automatic Telephone Manufacturing Co., Ltd., & Roseby, P. N. Electric furnaces for obtaining high temperatures. (21/8/20.)
171 214 Ellmore, F. A. A. Fault-indicator for use in connection with electric ignition systems. (24/8/20.)
171 216 Sturge, W. H. Electric fires. (25/8/20.)
171 218 Igranic Electric Co., Ltd. (Cutler Hammer Manufacturing Co.). Means for regulating alternating current circuits. (26/8/20.)
171 231 Igranic Electric Co., Ltd (Cutler Hammer Manufacturing Co.). Current regulators for incandescent lamps and other translating devices. (1/9/20.)
171 250 Greengate & Irwell Rubber Co., Ltd., & Povey, R. Junction-boxes for electric cables as used chiefly in collieries. (15/9/20.)
171 251 British Thomson-Houston Co., Ltd. (General Electric Co.). Electric transformers and like apparatus. (15/9/20.)
171 263 British Thomson-Houston Co., Ltd. (General Electric Co.). Systems of electrical distribution. (23/9/20.)
171 271 Sphinx Manufacturing Co., Ltd., & Clark, W. A. Sparking-plugs for internal-combustion engines. (25/9/20.)
171 279 Schroeder, F. W. Sparking-plugs. (5/10/20.)
171 285 Lion, A. A. Magneto pocket lamp. (11/10/20.)
171 313 Burton, H. Sparking-plugs. (2/12/20.)
171 317 Elverson, A. J. H. Terminals for high-tension electric cables. (10/12/20.)

APPLICATIONS FOR PATENTS.

April 24, 1922.

11 422 A. M. Taylor. Neutralising capacity currents on polyphase systems.
11 430 R. L. Hall. Hanger or rack for electric cables.
11 436 J. Robinson, H. L. Crowther & W. H. Derriman. Wireless apparatus.
11 456 C. G. Bennett. Switches.
11 462 F. M. M. de Vaulserre. Voltage transformer for c.c. (27/4/21, France.)
11 466 Western Electric Co. Selecting systems.
11 475 O. Ellinger. Electric connecting devices. (23/4/21, Germany).
11 483 O. Y. Imray (Hineline Engineering Co.). Electric stop motions for textile machinery.
11 487 R. Barwinkel. Supplying low voltage current from high voltage supply.
11 503 R. A. Driscoll. Electric furnaces.
11 508 A. Luzy. Device for electro-mechanical lamps for mines, etc. (4/8/21, France.)
11 511 C. V. Smith. Incandescent lamps.

April 25, 1922.

11 517 H. E. Dickerson. Portable electric power stand.
11 528 R. R. Leggott. Electric horns.
11 539 A. E. Thurstan. Electrical connection.
11 558 & 11 559. H. P. Stokes. Machines for dressing rails.
11 585 Metropolitan Vickers Electrical Co. Securing blades to turbine rotors. (10/5/21, U.S.)
11 592 Heinze Electric Co., B. Ames & P. J. Gillinson. Electric horns, &c.
11 600 B. T.-H. Co. (G.E. Co.). Electric heating units.
11 601 Western Electric Co. Means for reducing distortion in repeating systems.
11 606 D. C. A. Hulström. Receiving, reproducing or reinforcing sound waves.
11 611 J. Collie (Nikolsky). Electric indicating and recording mechanism for weighing apparatus.
11 613 Fallimento Soc. Anon. Manifattura L. Duca. Support for mounting electric head lights on automobiles. (28/4/21, Italy.)
11 617 V. Paivelecki. Electric safety lamps for mines, &c.
11 634 W. S. Smith. Electric conductors.

April 26, 1922.

CONTENTS.

Notes of the Week.

—◆—

The Faraday Medal.

The illness of the President during the Commemoration meetings of the Institution of Electrical Engineers in February robbed the function of a good deal of its glamour and success in the mind of the ordinary member. But those who were behind the scenes knew that in another respect things had not quite gone according to plan. For it had been decided, as Mr. Highfield disclosed at last week's meeting, tangibly to celebrate the Jubilee of the Institution by striking a "Faraday Medal" for periodical award to those whom electrical engineers may delight to honour. Now that the preliminary obstacles have been overcome we learn with no surprise that the first award of this medal is to be made to Mr. Oliver Heaviside. Mr. Heaviside's qualifications for this honour are too well known to require expatiation here. The aptest thing we can do, therefore, is to follow the example of a recent honours list in which the name of a very well-known gentleman was published with no explanation as to why he had received the distinction. For it was felt that his reputation was so world-wide that the reason for the honour was patent. It is the same with Heaviside and the Faraday medal.

The New Council.

At last week's meeting of the Institution of Electrical Engineers Mr. Highfield announced the result of the ballot for the election of officers and new members of the Council for the session 1922-23. Mr. F. Gill, Dr. W. H. Eccles, Mr. A. A. Campbell Swinton, and Sir James Devonshire will be the president, vice-presidents and honorary treasurer respectively, while the discrimination of the election among an embarrassment of choice has resulted in the lot falling on Messrs. J. W. Beauchamp, R. A. Chattock, F. W. Crawter, D. N. Dunlop, K. Edgcumbe, A. F. Harmer, and W. R. Rawlings. The unsuccessful candidates are therefore Mr. A. C. Cramb, Dr. C. C. Garrard, Mr. W. M. Selvey, and Mr. A. B. Hart in the official nominees list, and Mr. R. H. Fletcher and Mr. A. M. Sillar among those who were nominated from outside the Council. This result rather goes to support the view that the Council are better able to choose candidates who will receive general acceptance than are unofficial groups of members, however influential and enterprising. The strength of this argument is not lessened by the election of Mr. R. A. Chattock, who is too well known in the electrical industry to run the risk of being classed as a provincial. Nevertheless we hope that unofficial nominations will continue to be made, especially under the new bye-laws. To make these nominations is not only the members' right but their duty, in order that the Council may be as representative as possible.

Broadcasting Delays.

Electrical firms concerned may be trusted to meet the demands of the enthusiastic wireless amateur, actual and prospective, for all the equipment he requires. Indeed, there is already a good deal of activity towards this end. But it is not so certain that the "broadcasting" which will make the employment of this apparatus a useful and profitable hobby will be established quite so quickly as once seemed probable. A conference of the firms who were likely to be interested in this matter was called by the Postmaster-General on Thursday last, and a further conference of the firms themselves without the official element was held on Tuesday. From both these meetings the Press were excluded, which is rather a curious preliminary to a development which, whatever else its result, will mean the wider dissemination of news. Nevertheless

it is evident that matters are not going too smoothly, and that there is some difference of opinion, to put it mildly, on more than one point.

The Points at Issue.

THE principal point at issue at both these conferences has been not, of course, a technical, but a commercial, one. That element can unfortunately be kept out of few wireless discussions. The difficulty is to decide whether all the broadcasting stations should be placed in the hands of one firm, subject to safeguards of some description or other, or whether the stations should be formed into groups operated by different interests, so as to allow of competition. If the latter plan is adopted the patent bogey then takes the stage. Broadcasting by wireless telephony is impossible, we understand, without infringing the patents of a certain company, though that is disputed in other quarters. In any event licence to use these patents would be given, again under certain safeguards. A third point is whether small wireless manufacturing firms who do not contribute to the cost of broadcasting should be allowed to sell receiving sets. Here, then, are three controversial and important points which, if past history is anything to go by, will not be settled without a good deal of discussion. And as the POSTMASTER-GENERAL cannot start broadcasting without the assistance of the wireless manufacturers, even the most optimistic will agree that there must be some delay.

Technical Difficulties.

DELAY will also arise from the fact that no definite conclusions were, we understand, reached on the technical points raised at the conference. Unanimity was, in fact, only achieved on the proposed prohibition of both advertisements and news from the operation of the broadcasting stations. We consider ourselves that advertisements should be rigidly excluded (for one reason because their propagation would mean the crowding out of more interesting information), but that news, though not comment on it, should be allowed. The newspapers would lose very little by this, and would stand to gain by the interest that had been aroused. For the accounts given by wireless could be neither so detailed nor so circumstantial as those published in the morning or evening journals; and in any event the newspaper habit has become too ingrained to be eradicated so easily.

A Change and An Opportunity.

IF the present enthusiasm to possess a wireless telephone has no other result it will, we hope, give the amateur a tighter grasp on electrical knowledge and a better appreciation of scientific method. The wireless amateur is at present, we are glad to see, desirous of obtaining the fullest information about the apparatus which he will use, and this has been reflected by the issue by enterprising contemporaries of more than one text book designed to satisfy this craving. Reviews of already published wireless books, both for the expert and the amateur, are appearing in the columns of the daily papers, an event that is nearly, if not quite, unique, while now that wireless is the fashion it will doubtless be adequately boomed in all the accepted ways, with the exception that, as far as we have been able to ascertain, the information which is given is accurate, if a little dull, and not of the kind which we have so often had to criticise when commenting on other attempts to make an interesting story out of scientific or technical matter. This is a great change and a great opportunity for the electrical industry. And now that a start has been made we hope progress will continue along the same lines.

Some Manufacturing Companies' Results.

THE reports of five distinct manufacturing companies which have recently been published supply a further illustration of the comparatively prosperous condition of the industry notwithstanding the industrial situation and the stagnation in many other trades. For instance, the net profit of Callender's Cable and Construction Co. in 1921 was over £173 000, compared with £139 000 in the previous year, and after making the usual provision for depreciation and reserve and paying the preference dividend, the ordinary shareholders have been given 15 per cent., as in 1920, with a carry forward of over £150 000, as against £108 000. Another cable manufacturing company, Siemens Brothers and Co., announce a final dividend of 5 per cent. making 10 per cent. (tax free) for the past year. Though this is the same rate as in 1920, it must be recollected that the amount of ordinary shares is nearly £500 000 more, and there are also £300 000 of 10 per cent. new preference shares to be provided for, so that there must have been a substantial increase in the profits. Both companies are well organised, soundly financed undertakings whose business greatly expanded during the war and since the Armistice, and the reorganisation of the supply industry, apart from Colonial and foreign demands, should mean even increased prosperity in future.

The English Electric Co.'s Progress.

THE third company to which we may refer is the English Electric Co., whose profit amounted to £317 423, compared with £266 936 in the previous year. After meeting debenture and other interest, paying the preference dividend of 6 per cent., and placing £60 000 to reserve, an ordinary dividend of 5 per cent. has been declared, against 8 per cent. in 1920 and 1919. It will be noticed that the company, which, as our readers know, is an amalgamation of five engineering concerns, made £50 000 more profit than in the previous year, but the interest on the £1 250 000 of 8 per cent. notes absorbed over £15 000 more, the reserves are credited with £35 000 more and the amount carried is £9 363 higher than in 1920. In view of the present situation in the engineering industry this is no doubt a prudent course to adopt. The company's organisation has been steadily developed during the year; the various factories are specialising in certain classes of work; and the selling arrangements have been strengthened both at home and abroad. The result has been, as might be anticipated, increased efficiency and economy. Important contracts for generating plant, and for railway electrification in New Zealand, Spain and Japan have been secured, and there is no doubt that the company will secure its share of the important orders for British railway electrification, which will soon be placed. In addition, arrangements have been made, through the recently-formed Power and Traction Finance Co., to obtain a share of big foreign engineering contracts. Notwithstanding the present disastrous engineering dispute the outlook for the company seems to be promising and it should do at least as well in the present year as in 1920.

A B.T.H. Year.

Another company which has done very well, notwithstanding the unpropitious business conditions, is the British Thomson-Houston Co., which made a gross profit of £509 259, compared with £470 470 in 1920 and £412 399 in 1919. After allocating £160 000 for depreciation and reserves, paying interest on debentures and loans and the 7 per cent. preference dividend, the directors have decided to declare a dividend of 6 per cent. (tax free) on the ordinary shares, leaving £230 704 to be carried forward, or £5 000 more than the amount brought in. The company's report is a good record of expansion and development at Rugby, Birmingham and elsewhere, and new glass works is being erected at Chesterfield.

B. & W. Progress.

Babcock & Wilcox are also able to point to a larger gross profit (£807 500) than in any previous year, but owing to taxation and other liabilities the net profit is less by £7 300 than in 1920. The ordinary dividend is, however, maintained at 16 per cent., the usual provision has been made for depreciation and reserve, and the value of stocks in hand have been written. The expenditure on orders not invoiced is higher than in the previous year, so that the outlook in spite of the industrial dispute, seems to be healthy. On the other hand, Johnson & Phillips have had a disappointing year, the net profit being only £42,737, compared with £98,406. The stock in trade and work in hand have had to be written down drastically, and the coal strike and the engineering dispute must have increased the company's difficulties. However, the firm is an old-established one, with a good connection and electrical reputation, and we confidently hope that it will be able to resume the payment of an ordinary dividend again next year.

Accurate Metering.

A reference in the Bulletin of the National Electric Light Association to some courses of lectures for electric meter men at the Yale and Florida Universities, is a reminder of the very important part which meters play in electricity supply undertakings. At the present time, when the price per unit is high, the question of correct metering becomes correspondingly important. But it is just where correct metering becomes quite crucial, namely in small undertakings, that the provision for accuracy is usually most lax. This is a matter of serious concern, since faulty registration in meters is normally against the undertaking—that is, a meter in use tends to under-register. In addition, of course, there are the faults such as failure to start when one or two lamps are switched on, which also means a loss to the undertaking. It can be easily seen, therefore, that inaccuracy or faultiness of meters may affect revenue to a most serious degree. But this seriousness seems to be by no means as widely appreciated as it should be. Extraordinary "economies" are often practiced, such as leaving meters out on duty for an unconscionably long time, neglecting to have them regularly inspected and tested for starting, and so on. Further, the duty of superintending meters and inspecting them on circuit is too often left as an odd job to a man who is very far from a specialist. And this is in face of the incontestable fact that a skilled man to look after the meters would be a most profitable investment, while a more frequent change of meters would repay the extra capital outlay. There seems always to have been in the industry an unfortunate tendency to under-estimate the importance of a proper meter department, although it is a matter which might most beneficially receive careful consideration, as it evidently is doing in America, to judge from the Bulletin we have mentioned.

Private Generating Stations.

By Sec. 11 of the Electricity (Supply) Act no electricity authority can establish a new, or extend an existing generating station or main transmission line without the consent of the Electricity Commissioners. This restriction does not, however, apply to a private generating station, except that the Commissioners may make regulations as to the type of current frequency and pressure which shall be used, provided that they are so framed as not to interfere with the economical and efficient working of the business for which the supply is generated. The Commissioners have now decided not to make regulations as to type of current, frequency and pressure of private generating stations having an installed capacity not exceeding 50 kW., and no notification need, therefore, be made to the Commissioners regarding the establishment of such stations. It is obvious that private plants of the size indicated cannot play an important part in the economy of a national system of electricity supply and no useful service would therefore be gained by attempting to control them so that the Commissioners have relieved themselves of a duty which might have been arduous without being useful.

Limited Liability Companies' Contracts.

Wiring contractors would do well to read and carefully note the judgment in the case of Pittman *v.* May. It shows, among other things, the necessity of having a definite contract before work is undertaken and the desirability of knowing whether the financial position of a newly formed limited liability company is such as to justify credit being given. Unfortunately, contractors are too often content with verbal instructions, and then when they have finished a job they find they cannot obtain payment. In the present case an electrical engineer was instructed to wire a dancing hall owned by a limited liability company which went into liquidation before the whole of the work had been paid for. In the circumstances the contractor sued the person who originally instructed him, together with another, who were alleged to be in partnership for running the hall. Unfortunately for him, it was proved that he had received three cheques from the company in part payment for the work, and the judge reluctantly held that only the company was liable. The contractor could have refused to accept the cheques and he could have insisted upon payment by the person from whom he received the instructions, but as he did not he lost £200, the balance owing for the work. We sympathise with him in his misfortune, but we hope that he and other contractors in a similar position will be wiser in future; that they will see that contracts are clear and unambiguous in their terms, and that they will take care credit is only given where it is justified.

The "Central" Appointment.

A little while ago an important railway company took the retrograde step of placing its electrical engineering department under the chief mechanical engineer. But it has been left for the delegacy of the City and Guilds (Engineering) Institute to appoint a physicist to the chair of electrical engineering at the Central Technical College. For Prof. C. L. Fortescue (our criticism is quite impersonal),

who is to succeed Prof. MATHER, now holds the chair of physics at the Royal Naval College, Greenwich, and his sole connection with electrical engineering is through wireless science. This appointment is therefore a great and unnecessary mistake, for which the delegacy is alone to blame. We are second to none in our recognition of the need for maintaining progress in wireless work, but at the present time the heavy engineering branch is more important both because of its greater technical scope and of its greater commercial possibilities. Embryo electrical engineers require above all a thorough grounding in the fundamentals of engineering practice and to be taught how to consider problems from the engineering view point. It is difficult to see how Prof. FORTESCUE, with the best will in the world, can achieve these aims.

It is difficult also to see what can be done. The appointment can hardly be cancelled, and the best that can be expected is that it will do a minimum of harm. That result will depend on Prof. FORTESCUE. He should realise his limitations, and do his best to carry on the high tradition of his new position which it is vital should be upheld by every means in his power.

Indian Electricity Supply.

THOUGH there are a number of electricity supply and tramway undertakings in India, mainly owned or controlled by British companies, there is, strange to say, no organisation to protect their common rights, no association to enable the engineers and officers to come together and discuss problems and difficulties which must have an equal interest for them all. The immense distances between the various towns and industrial centres, and the expense and difficulty of travelling are mainly responsible for this splendid isolation, but we are glad to see that steps are now being taken to remedy what is an unfortunate state of affairs. From the purely electrical point of view, the Empire of India is one of great promise. Though some progress has been made, there are clear indications that much more will be made in future. There is an increasing demand for power and lighting, and this will have to be satisfied. There are vast sources of water power available, and if means of development were provided there would be ample supplies of electricity for industrial power, for the electrification of the railways, for irrigation and other purposes. In a country so undeveloped cheap power is no less essential than in an overpopulated land like ours, and electricity supply is given a chance of developing under the most modern conditions, a chance which we hope will be seized with both hands.

Useful Survey Work.

MUCH useful survey work has already been carried out under the direction of Mr. J. W. MEARES, the Government electrical adviser; and the chief obstacle to progress seems to be the lack of suitable legislation. We hope, therefore that the British Indian Electric Committee, which is representative of the Supply Companies, when they have their new organisation, will take up this important matter, and we should also like other British engineering associations to study the situation and make suitable representations to the Government of India upon it. Until reasonably fair and attractive concessions for the development of water power are available engineers and financiers will not be induced to risk their skill and capital in the country. In America, a highly-industrialised country, concessions are granted for 50 years, but for India a longer term is necessary; and in addition good facilities should be given for the purchase of land, for the erection of works, for the acquisition of way leaves for transmission lines, etc.

Trade Outlook Better.

THERE is evidence that the wave of trade depression which has affected the country for some time is passing, and that the political agitation, which has, no doubt, been aggravated by bad trade, is dying down. Consequently the outlook is distinctly better, and the future of industry, particularly of the electrical industry, is promising and should provide a good investment for capital. Apart from any new hydro-electric projects or electric railway schemes, most of the existing undertakings are making rapid progress, and extensions of plant and mains have had to be undertaken. For instance, the Calcutta Electric Supply Corporation reports that it is swamped with applications for new connections; its output for 1921 was over four million units more than in the previous year, and its ordinary dividend and bonus are maintained at 11 per cent. In Bombay, where a similar situation prevails, there is a large demand for electric power for the cotton mills and factories. Other supply companies are also able to point to increased connections and to a sustained demand for both light and power.

Co-operation by Conference.

IT is, therefore, satisfactory to learn that in future there is to be greater co-operation between the various undertakings in India. It is hoped to inaugurate an annual conference of the chief engineers and officials similar to the annual gatherings of the I.M.E.A. and the Municipal Tramways Association. Of course, the circumstances in India are widely different from those which prevail in this country, but nevertheless there should be plenty of useful work for such a conference to do. There are many engineering problems, administration questions and other matters which could be discussed. In addition, the legislation affecting electricity supply, import duties, industrial relations and many other things can be dealt with much better by co-operation than by individual action. Therefore, we welcome the new organisation, and we hope it will be as successful as the British associations upon whose constitution it is, we believe, to be modelled.

The casting vote it will be seen, remains with the politicians. In this country they have done the electrical industry no good. We hope that in India, where the political situation is so difficult, a means will at least be found of encouraging, not discouraging, a most important development.

Industrial Essentials.

THE only commentary on life which could do justice to the present position of the engineering industry is one of Æsop's fables. We have not a copy of that leader writer's *vade mecum* at hand, but we feel sure that among its ancient wisdom is to be found some succinct and enlightening description of a state of affairs where all parties are working to their own hindrance. But it is a state of affairs where, if the parties would only recognise the community of interest that exists between them and the excellent results which would follow from honest common effort, they could really obtain for themselves the prosperity which they are attempting to achieve by means which are as little likely to lead to success in actuality as they are suited to the politics of

some utopian kingdom. There is, we recollect, something about grasping the shadow and losing the substance in the authority we have just quoted. That is what the engineering industry appears to be doing now. It would be as well that all concerned should look facts in the face and learn the lesson that they teach before it is too late. At present cynical laughter is the only fit comment on both their practice and performance.

Theories as a Diet.

During the past few years it may be said with some truth that we have been feeding on theories, basing our actions on suppositions and trying to build up a fabric of a better and more efficient industry upon a foundation which time has speedily shown to be quicksand. That is no cause for blame; it is a natural reaction from war-time conditions. Still less is it a cause for blame, or even regret, that much of that fabric is good and well designed, and that, given sounder foundations, it can still take its place in the building which we must still continue to strive to erect. The Whitley Council movement, the realisation of the need of research, the ethical and physical value of welfare work, the introduction of labour-saving and labour-aiding devices so as to make the worker less of a machine and more of a human being are all stones in the temple of the new industry which will be as useful in the future as they are at present. But these parts of sound construction must not be allowed to conceal the fact that we have not yet found the way to build an industry that shall be well established throughout, or rather that we have not yet cleared away the numerous obstacles which are preventing that construction. The design itself is well conceived. It is its realisation that is difficult.

The Difficulties that Exist.

To consider the difficulties that stand in the way of regaining industrial prosperity may make a solution of the problems that have to be faced easier. It is obvious that manufacturing conditions are undergoing a profound change. Selling the product when it is made is perhaps the most difficult of all the difficulties. This is indicated, perhaps not so clearly in engineering as in other branches of industry, by the feverish activities which are made to obtain the smallest order, in the cajolery of, in the prayers to and almost in the intimidation of the buyer, and generally in the amount of energy which is being expended, if not wasted, to secure what can only be in the nature of things a very small return. The right sort of propaganda should receive every encouragement from the modern manufacturer, but to expend time, money and energy in employing the wrong kind is useless.

A Significant Change.

But more significant, because less directly connected with selling, which after all is naturally a conflict of psychological opposites, is the change which has come over the production side of the factory. The time has gone by when the manufacturer bought at the lowest and sold at the highest price he could without any clear idea of what the connection was between the two sets of figures or whether it was possible to improve the efficiency of his factory (in the mechanical sense) by reducing the margin between them. And providing Mr. MICAWBER'S idea of happiness was realised in his balance sheet he did not much care.

Counting the Cost.

Now the cost, and every factor which has an influence on the cost, of every article and part made in the factory is known, and its progress through the shops is watched and controlled so that the cost is kept at its minimum, and so that its effect on other parts which are passing through the shops is such that their cost is also kept at a minimum. Though it may be argued with truth that the multiplication and complication of some costing systems are more apparent than their utility, it is axiomatic that to know the cost of any particular product, however small, of the factory and to be able to check any waste that occurs in its production are results that are well worth striving for and are an advance towards that real simplicity which it is worth while some effort to make.

To know of what every part of the organisation is capable must, therefore, be the aim of the manufacturer of to-day. For only with that knowledge can he be assured of a return for his capital and labour, with a steady upward movement towards that prosperity which shall allow further expansion and a greater scope for his efforts.

The Most Difficult Question.

It is the intention in the special Manufacturers' Issues of THE ELECTRICIAN, the third of which we publish to-day, to deal with those questions of interest to the industry which can be properly said to lie within the four walls of the factory. And of these, especially at the present time, the most important and the most difficult to solve is that of Labour. The manufacturer has had a good deal of success in dealing with the organisation of his shops, in preparing costing systems and in instituting research, but his success in dealing with the human element as represented by his operatives has not been so patent, and, if we are to judge by present circumstances, might be more aptly described as failure.

A Psychological Problem.

This is to a large extent due to the worker himself, who may be labelled as a mass-individual. In other words the worker is employing organisations which have been laboriously built up for other purposes to further the interests of his own class at the expense of all the others. That way madness lies. The Socialist is at bottom the most individual of men, and equally the Trade Union is the most individualistic of societies. It is this narrowness of outlook which is at the bottom of all Labour difficulties, and bids fair, if recent defeats are any guide, to lead to the immolation of the Trade Union movement. This immolation would be disastrous, but if reluctance to take lower basic wages is combined with a refusal to do more work, no other result can follow. And when to this is added a disinclination to submit to the slightest discipline, things look very black indeed—and blackest of all for the Trade Unions. On the employers' side matters are not what they should be. There is a rigidity and conservatism which can only lead, as they have done, to violent clashing. The alternative must lie in a determination to widen the outlook by seeing the other side's point of view and by a real working together on the lines which the Whitley Council movement has shown leads to a considerable share of success.

It is because the organisation of the engineering industry, except in the comparatively small things, is so confused, and because those most concerned in it seem blind to the confusion, that we have labelled it as we have done in our opening paragraph. It is difficult to see how the present conditions can be changed without a return to something like individualism, and certainly without a return to something like discipline among all parties.

Some Problems of Modern Manufacturing.

By P. J. PYBUS, C.B.E., Managing Director English Electric Co.

However much the pendulum has swung over from the optimism which followed the Armistice to a depression which is equally unjustified, there is no doubt whatever that lately the engineering works of Great Britain have had opportunities for gaining experience in the real science of production such as may never recur. Everyone was a superman in those days, and the process of recovering a slight sense of proportion has been in some cases a fatal operation and in every case somewhat painful. In my opinion the prime mistake did not lie with the works manager or those responsible for production at all. Industrialists are not the only ones who can be wise after the event, and it is regrettable that the economists who now fill our papers with statements that the slump which has hung over industry for the last year was a natural result of all wars did not secure the same publicity for this prediction immediately after the Armistice as they now give to their views when the depression is plain to everyone. Industry made the mistake of allowing "the tail to wag the dog" when they were deciding on their post-war programmes. Having got a plant in many cases financed by Government funds, and of a highly repetitive character, they immediately looked round for something to produce on it, with the result that the market is flooded with stocks of articles resembling war products in shape and dimensions for which there never has been nor ever will be a sufficient market. There is a plague of articles which are short in length, round in shape and which can be handled without a crane, and the wise ones turned down every proposition which came into this category as one in which over-production was certain. The happy undertaking to-day is that which has had the courage to close down its war extensions, to readjust its ideas as to possible turnover and to see to it that the foolishness of the Armistice year is forgotten and that every scrap of the knowledge and experience of production which was gained during the war is made use of wisely and in a moderate way.

Some Useful Wartime Lessons.

The knowledge gained during the war must not be lost in a revulsion from the extravagances of the war period. In nearly every modern works machine tools which before the war were unknown to the executive have come to help costs. Grinding and hardening have become, for those who were amateurish before the war, exact sciences. The extended use of gauges, manufacture to perfectly definite limits and the resultant elimination of shoddy operations for making one part fit another have promoted many of our post-war products into a class which cannot be equalled anywhere in the world. The whole of the internal organisation of factories has been revised. Elimination of guess work has not only come about by the use of limit gauges and more accurate methods, but there are few works to-day which have not entirely revised the basis upon which piece-work prices are calculated. The old system of barter, with all its inaccuracies and irritation as between master and man, has been replaced by something more accurate and scientific.

The Importance of Costing Methods.

I think it will be agreed that the post-war system of estimating works costs is an improvment, with the result that many contracts have been secured against world competition which before the war would have been lost. The importance for British industry of a proper system of costing for estimation purposes cannot be exaggerated, and, much as most of us abhorred the activities of the costing departments of the Ministry of Munitions, there are few who did not gain something by demands for actual costing as against mere "rule of thumb" methods. The real menace to the prosperity of an industry is the concern which does not know its true costs and which quotes accordingly. It is often necessary in bad times to quote prices below cost, but there must be a price at which it pays better to leave work than take it, and the man without the accurate costing system does not know what this limit really is. A practice which ruled in few factories before the war was a definite reconciliation of the costs which were used for estimating purposes with the books of the company. Often the results shown by the works accountant were irreconcilable with the distribution of labour and charges which formed the basis for the original quotation. In this direction I think there was a great gain during the war.

The tendency with regard to piece-work prices which had been developed in a few factories before the war, and which made it possible to show to labour a detailed calculation as to feeds and speeds, grew very much from 1914 onwards. It was the vast numbers of the same product which brought home both to the employer and the workman the necessity for scheming in detail the exact method by which a piece of work could best be carried out, and the five years' war experience of repetition on a vast scale brought home to everyone the impossibility of securing real efficiency unless a good deal of thinking as to method was done before work actually started.

Unscientific Price Fixing.

I believe that, suicidal as has been the attitude of certain sections of labour regarding piece-work, unscientific methods of fixing prices contributed largely to the support which the organised objection to payment by results received after the war. In many shops before the war new prices were fixed during the boom with far too large a time allowance; then, when competition became greater, the employer had either openly to reduce his piece-work price, or alter the method by which the job was done in order to get out of an established piece-work price the maintenance of which meant that his products were unsaleable on account of their high cost. The more scientific practice of fixing piece-work times, with the evidence clearly before employer and workman, has the effect of removing once and for all any question of an enormous gamble for either party.

Rate-fixing à la Mode.

Rate-fixing as it is commonly understood has in practice often meant simply this, that the employer or his representative fixed rates, scientifically or unscientifically, but in secret, wrote them down on a card and gave them to the workman "to take it or to leave it." There was no pretence of making the operation a bargain between the parties, no opportunity for either party in any open and straightforward manner to have rates reviewed when once fixed. This system is fair neither to the employer nor to the workman. The old notion that any foreman or his clerk was good enough to fix rates is exploded. The job calls for complete familiarity with the work done in the shop and the machines employed; for special training; and, what is even more important, for a human manner. There are other walks in life than the diplomatic service for which a rough tongue is not a recommendation, and rate-fixing is one of them.

The Whitley Movement.

But not even the most efficient and the most tactful of rate-fixers can avoid making mistakes on occasion or always succeed in convincing the workman that he is being given a square deal. His work must be supplemented by proper machinery for appeal, which is quick in action and not cumbersome in operation, for the rectification both of a price which is too low and of a price which is too high. It is in this direction that most progress has been made, and it is a matter of the very gravest anxiety to the industry as a whole that any feelings caused by the lock-out shall not interfere with the co-operation which has grown up so

splendidly since the Armistice. The movement originated by Mr. Whitley, together with the establishment of Works Committees in many factories which had no consultative body at all before the war has, in the main, been successful. The Works Committee to-day differs in most factories very materially in scope and power from those created immediately after the war. But there are few factories on which this movement, idealistic though it may have appeared at the beginning, has not left a permanent impression. While many of the original functions of the Works Committee had to be omitted from their constitution owing to the fact that they did not give the proper representation to the organisation of the great craft unions, the movement has come to stay.

Improvement in Working Conditions.

In what was known by the general and quite unsuitable expression, "welfare work," the activities of the war have produced a definite change in the factories and workshops. You have only to walk round the average engineering works to see on all sides improvements in hygienic and sanitary conditions of the shops. Most of the larger works have appointed, and still retain, even in these bad times, their male and female supervisors. The work among girls was easier to initiate than that amongst boys, but it is remarkable that in many of the shops the welfare activities amongst the lads have produced more permanent results than any other form of welfare work. In many works large areas of recreation grounds, containing club houses and in some cases halls in which dancing and concerts take place every week, have rendered the works a definite social centre. Some of the more ambitious schemes will possibly fail to continue on their present scale, but those in which the management is vested in the workpeople themselves will undoubtedly continue to flourish. I do not think that there is any room for a large social organisation connected with a factory situated in a large town where the workers live a considerable distance from their work and where recreation is easily obtained near their homes, but in more isolated works the factory has, since the war, become more than a mere workshop—it is a centre of many activities ordinarily outside the scope of an engineering company.

A Real Advance.

We have, in the last few years, grown so accustomed to lighter and better workshops, proper medical and hygienic appliances and all that these improved facilities make possible, that we are apt to overlook the real achievement which has been effected. If we think back to the time of our own apprenticeship the change is almost unbelievable. The workman hurrying along with his tea-can in one hand and a tin box containing food in the other is now seldom to be seen. The modern canteen, generally spotlessly clean and equipped like a modern restaurant, has changed all that. The ambulance room, with the trained nurse in charge, has replaced the "belt-mender" with his sticking plaster and friar's balsam as a remedy for all wounds. Proper changing rooms, with adequate washing accommodation and a host of other amenities, have changed the whole appearance of the workshop of to-day, and while before the war there were many modern and advanced establishments, it is not too much to say that the more general adoption of such improvements is a direct outcome of the war and a step which was too long delayed both in the interests of the workman and his employer. Let no one imagine that these changes, however far they are pursued, can solve the problem of workshop management. It is easier to design an automatic machine than an automatic man. The disciples of Mr. Taylor will continue to fail if they do not appreciate how complex is the combination of the man and the machine, and how impossible a task it is to analyse the human mind into simple terms. Education and social progress have been applied for generations to the deliberate enlargement of the human aspirations of the workers, and to think to-day that men can be controlled like a machine by the setting of cams is to believe that it is possible to unscramble an egg.

Reviews.

Hydro-Electric Engineering. Vol. I. Civil and Mechanical. By Prof. A. H. Gibson, D.Sc., and H. D. Cook, M.Sc. (London: Blackie & Son, Ltd.) Pp. xx. + 232. 25s. net.

Prof. Gibson is editing two volumes on hydro-electric engineering—the present one deals with the civil and mechanical side; the second volume will deal with the electrical equipment and lay-out, the economic side of the question, and with the possibilities of tidal power. Of the volume under notice, Dr. Gibson is responsible for the sections on: Rainfall and run-off; the flow of water and its measurement; the available power, storage, &c.; hydraulics; the development of water-power schemes; turbines; speed regulation; and water-power reports. Mr. H. D. Cook contributes the sections on civil and mechanical engineering works, and on general arrangement of stations.

Reading this book has been a very refreshing task. The Editor has chosen his matter carefully, and by refraining from an extensive use of purely descriptive matter, has retained ample space for the "real stuff" in the form of calculations in hydraulics, turbines and speed regulation. Thus the work is essentially technical in character, and will serve as an admirable text book. It is doubtful if there are many subjects of more immediate interest to civil, mechanical, and electrical engineers than the utilisation of water-power for the generation of electrical energy, and the Editor might have written at even greater length on certain aspects, such as the linking up of stations. The various means that have been adopted of late years for obtaining a continuous supply of energy from water-power form a very instructive study, and might well provide a section in a book like the present. The electrical designer will not find much comfort in the fact that the runaway speed may equal three times the normal speed. On this point at least the electrical engineer can deny responsibility, unless perhaps it is his duty to find the means of preventing this danger!

It is an authoritative book, which can be thoroughly recommended to engineers. Both printing and illustrations are good, though we should like to see "0" placed before the decimal point—0·4 is much better than ·4 in every way.

S. Parker Smith.

Boiler Inspection and Maintenance. By R. Clayton. (London: Sir Isaac Pitman & Sons, Ltd.) Pp. 118. 2s. 6d. net.

This little book is a useful guide for boiler inspectors and others interested in the close examination of steam boilers.

As a practical and experienced boiler surveyor, Mr. Clayton knows exactly "what to look for" when a boiler is down for inspection and overhaul, and gives the result of this experience in a concise and readable form.

In the initial chapters he deals with the principal types of boilers, including Lancashire, water-tube, vertical, loco., and others, analysing their salient features, and calling attention to possible constructional defects, normal and abnormal effects of wear and tear, water corrosion, and other causes.

The later chapters are devoted to accessory steam plant, such as economisers, superheaters, water softeners and mechanical stokers, and contain many practical hints on the care and maintenance of valves, pipe lines, fittings and other details which will be useful to all operating engineers.

In the preface the question of coal economy is lightly touched upon, but the scope of the work does not call for exhaustive treatment of the operating side, and this phase is not, therefore, developed to any extent. At the same time, there is no doubt that closer attention to the question of maintenance will materially reduce the risk of breakdown, and Mr. Clayton's treatise may therefore be recommended as a useful addition to the boiler engineer's library.

Percy E. Rycroft.

Electricity and Safety First in Factories.

By W. H. SEAL, H.M. Deputy Superintending Inspector of Factories.

Mr. Seal's article is written to stimulate interest in the important problem of how safety can best be insured in our factories. This is both a human and an economic question, and in its solution electricity can be of the greatest assistance. Mr. Seal suggests a code of safety rules and calls attention to the legislative difficulties which prevent the full blossoming of "safety first." Certain precautions desirable in using electrical machinery are discussed in detail.

It is only possible in the brief space alotted to me for this article to touch the fringe of such an interesting and important subject; if, however, anything herein stimulates more active interest or encourages further efforts by those to whom it appeals, it will not have been written in vain. Moreover, this is not an official review, but some reflections of my own personal impressions.

Politics and Safety First.

The late Mr. Gladstone once defined the science of politics as "to make it easy to do right and hard to do wrong"; the same words apply equally to the science of the subject under review, particularly from the electrician's point of view, for the art and functions of true statesmanship consist, not so much in trying to deal successfully with national needs and international problems as they arise, but, what is far more important and valuable, in foreseeing and averting dangers which threaten the State. Similarly, and with equal force, this applies when dealing with "Safety First in Factories," which may be summed up in the prosaic words, "prevention is better than cure."

Apart from the problem of creating a more harmonious and better co-operative relationship between employers and employed—a most desirable achievement in the present state of industry—no industrial issue of recent years has become, perhaps, so prominent a theme for discussion, or involves more important prospective results.

This Country the First.

There can be no question but that this country was the pioneer in this desirable movement, mainly, perhaps, owing to its excellent Factory Acts and their administration; but its *commercial* value was quickly recognised by employers of labour and insurance intellectuals in America, which country, with its usual activity and hustle, was not slow to explore and develop this comparatively unknown sphere of utility, so that it has actually outdistanced us in the great strides made and wonderful results achieved.

True, its propaganda may appear sometimes crude in conception and somewhat gruesome in the illustrations used to illuminate its efforts; still, the movement is so widespread, the efforts so forcible, and its promoters so sincere, that, judged by results, "it gets there"; this is proved by facts and figures which are unimpeachable, but which space forbids being chronicled here.

The Pathos of Commerce.

The subject under review assumes additional prominence when we try to realise the constant and continuous toll made upon our industrial life, and the human misery involved by the fact that during 1920 accidents reported under the Factory Acts to H.M. Inspectors totalled 1 404 fatal, 42 012 due to machinery, and 94 286 others. And, quite apart from the necessity of complying with safety requirements enforceable under the Factory Acts, and the moral obligations arising out of the human aspect, there is the industrial side—viewed from the employers' standpoint—and this is the one with which, for the present, we are here mainly concerned; and thus the question naturally arises, does "Safety First" pay? Leaving out other considerations, the issue may be thus expressed: is there, commercially, an adequate return in interest to an employer for the capital outlay involved in carrying out the provisions to ensure its success? One way of recovering part of such cost would probably be in a reduction of insurance premiums when protective measures were adopted to the company's satisfaction. This is done in the laundry trade, where the Lancashire Mutual Insurance Association allows 5 per cent. discount off premiums when the machinery is protected up to the standard required by its inspectors, whose expenses are paid by members of the Association, and occupiers are keen to reap the advantage.

The Cost of the Worker.

Further, the question is partly answered by asking whether we fully realise what it costs the State to feed, clothe, educate, etc., a worker until the age of productiveness, either professionally or industrially, is attained; and even after that period is reached there are still years of probationary labour required before such a worker can give, either directly or indirectly, back to the State his own cost of production. Hence it follows that whatever can be done to secure the safety, physical comfort, and welfare of each producer is a valuable asset, not only to the breadwinner and his household, but to his employer and the State. No employer willingly allows his machinery to become obsolete or to neglect its efficient working and subsequent impoverishment for the sake of necessary repairs, adopting improved and more up-to-date methods, or, it may be, even the use of a little oil. And so it is with the human element in industry: whatever tends to make the producer less efficient, whether by unhealthy or unsafe conditions, is unjust to the workers, an inconvenience and a loss to the employer, and wrong to the State, for all this has to be repaid either in lessened production, compensation, insurance, etc., etc.

The late Charles Dickens must have been gifted with a prophetic vision of the partial solution of this problem when, 70 years ago, he said, "If ever there was a time when any one class could of itself do much for its own good and for the welfare of society—which I greatly doubt—that time is unquestionally past. It is in the fusion of different classes without confusion; in the bringing together employers and employed; in the creating of a better, common understanding among those whose interests are identical, who depend upon each other, and who never can be in unnatural antagonism without deplorable results."

How Electricity can Help.

And there is no field perhaps which affords such scope for progressive safety devices as the electrical; already much has been done, but very much more can, and must, be done. The first essential is the elimination, as far as practicable, of risks arising from overhead driving shafts, pulleys, and belts, the cause of so many and serious accidents, which can be greatly reduced by use of direct local or basement drives, to a minimum. No one visiting factories, great or small, can fail to observe the network of potential risks which everywhere prevail from unsecured loose belts suspended from overhead shafts, putting belts on pulleys, oiling bearings with shaft in motion, and the use of unsuitable ladders in work incidental thereto, etc. Other advantages of the electric drive include:—

(a) *Flexibility.*—The machinery in the mill can be arranged in the manner most suitable for convenient operation, without having first to consider whether it is possible to drive the machine in the position chosen. Alteration and extensions can be easily and efficiently carried out. The buildings can be scattered over a large or irregular area without appreciable disadvantage.

(b) *Lighter Building Construction.*—The absence of heavy mill gearing when electrical drive is adopted will often permit of a lighter type of building construction.

(c) *Sectional Working.*—Although most textile mills usually run at full load throughout working hours, cir-

cumstances sometimes arise which necessitate the operation of only a portion of the machinery. In such circumstances a prime mover does not operate at its maximum efficiency, and at the same time the percentage loss in friction increases, due to shafting and belting running round light. With a well-arranged electric drive, using purchased power, sections of the mill can be shut down, and the remaining sections will still operate at full load efficiency, whereby considerable economies are affected.

(d) *Smoothness of Drive.*—The individual motor drive of certain classes of machines will assist in obtaining a smooth and constant speed drive, especially if belts can be eliminated altogether. Such irregularities in speed as may be obtained from a belt drive are well known to have a very adverse effect on production, and one of the chief advantages of the electrical drive is that it enables the belt drive to be replaced by direct drive where desired.

(e) *Speed Variation.*—Where machines are required to be driven at variable speed the variable speed motor offers an ideal form of drive, as the speed can be perfectly and easily controlled, and it is much simpler than any mechanical variable speed device.

FIG. 1.—LARGE WOODWORKING PLANT WITHOUT OVERHEAD DRIVING SHAFT, PULLEYS AND BELTS—THE PIPES SHOW SYSTEM OF MECHANICAL DUST EXTRACTION.

(f) *Reduction in Breakdowns.*—The breakdown of a prime mover in a steam driven mill is a very serious matter and often involves a prolonged stoppage. On the other hand, a breakdown or failure in an electrically-driven mill, using purchased power, will, generally speaking, only necessitate the shutting down of a portion of the machinery, and that for a short time, as a faulty motor or cable can be quickly repaired or replaced. Where electricity is privately generated, this advantage of course, cannot be claimed. Apart from the breakdown of the prime mover in the case of the mechanically-driven mill, there is always the question to be considered of the breakdown of some detail in the mechanical drive which may shut down the mill for some considerable time. With the sectionalised electrical drive this disadvantage does not exist to the same extent in either the scheme using purchased power, or in that where the power is privately generated.

(g) *Ease of Control and Upkeep.*—Electrical energy can be very easily and accurately measured, and such measurements afford a continuous indication of the state of the machinery and the amount of work beng done.

(h) *Increased Light.*—Due to the reduction in the amount of overhead shafting, belting and other transmitting media in an electrically-driven mill, more effective lighting, both artificial and natural, can be obtained.

(i) *Improved Welfare of Personnel.*—The reduction in the amount of shafting belting, etc., with electrical driving improves the safety, appearance and cleanliness of the mill, thereby adding to the comfort and health of the staff and to the ease of supervision.

Good Conditions Assisted by Electricity.

The accompanying illustrations (Figs. 1 to 3) serve to emphasise the foregoing where direct electrical drive operates, whilst, in addition, it is possible by suitable gearing to arrange for the stoppage of any machine from various points by means of push-buttons, which of course, involves the use of an automatic circuit breaker, contactor, or some electro-magnetic means of holding the switch arm in position.

Further, it is practicable, by means of automatic starting gear to arrange for the starting and stopping of electrical motors from points remote from the motor. For example, a " blower " for a foundry might be installed in an archway where it was difficult to fence it, so as to safely approach it whilst running, but it could be arranged, by means of push-button starters interlocked with the machine house door, and from outside, so that there would be no possible danger to the operator There are many variations of this method of controlling machinery, but in dangerous places it is quite possible to make starting independent of visual or sound signals. Where basement drive prevails, local pulleys and belts immediately above the working floor can be easily railed off or shielded whereby the only risks arise from the moving parts of machinery, which, in turn, should be adequately fenced as far as practicable.

A Code of Safety Rules.

Having adopted all reasonable precautions for adequate protection from dangerous machinery and conditions of employment, the next step is to try and enforce their use, and the following " Safety Rules " are in successful operation at a large and important works in this country :—

1. ALWAYS BE CAREFUL. Make sure you are right before you proceed with your work.

2. If you have ANY DOUBT about how any work given you has to be done, or if you have ANY UNCERTAINTY as to the manipulating of any machine you are set to operate, SAY SO. Your foreman or overlooker will help you. DON'T TAKE A CHANCE.

3. USE EXTRA CARE whenever you see a machine painted RED, or where you see a RED DISC. Remember personal caution is the greatest and best safety guard. Want of care often does more harm than want of knowledge.

4. REPORT any DANGERS you see to your foreman AT ONCE. Cultivate the " Safety habit."

5. If there are any safety guards or devices on your machine, be sure they are in place before starting. Never start a machine until you have made sure everything is in order.

6. Do not wear clothing with unfastened or ragged sleeves. These may be caught in machinery.

7. All GIRLS must wear their HAIR NEATLY COILED to the satisfaction of the forewoman, WHEN AT WORK.

8. Larking or fooling is strictly forbidden. Do not throw anything.

9. Do not leave any boards lying on the floor with nails protruding. You may lame a workmate for life.

10. DO NOT OIL SHAFTING OR MACHINERY IN MOTION without direct orders from your foreman.

11. Do not use a ladder on wooden floors unless it has safety spikes or feet.

12. Do not use tools with burred ends, or hammers with cracked or broken shafts.

13. Do not pile material so that it can fall.

14. PROTECT the premises AGAINST FIRE. A fire in these works may put many people out of work. PREVENTION IS BETTER THAN CURE.

15. Help to keep the factory and plant clean. There is less chance of accidents happening.

16. IF YOU ARE INJURED, no matter how slightly, REPORT AT ONCE to your Charge Hand or Foreman. NEGLECT of proper

attention MAY CAUSE PAIN AND SUFFERING as well as LOSS OF WAGES TO YOU. Skilled treatment is always available.

The Use of Safety Bulletins.

In large works much can be done by a competent safety engineer or inspector with time and authority to supervise and enforce safety conditions, but in smaller works this must necessarily devolve upon the employer, or some responsible manager, or foreman; but in either case their efforts can be very usefully supplemented by warning placards—sometimes known as safety bulletins—exhibited in the works, of which the following are typical :—

FIG. 2.—WOOLLEN MILL—TWISTING FRAMES (SHOWING PART OF DISUSED MILL GEARING AND PULLEYS).

THINK SAFETY AND PRACTICE IT.	BETTER BE SAFE THAN SORRY.	PREVENTION OF DISTRESS IS NOBLER THAN RELIEF.	*DANGER.* DANGER SIGNS ARE FIXED FOR YOUR SAFETY. DO NOT DISREGARD THEM.
FOOLING. Many accidents are caused by fooling, horseplay, and distracting attention of others. Be sensible.	*HABITS.* It is better to lose a minute in avoiding an accident than a month in nursing an injury.	*WOUNDS.* Septic wounds, however slight, require careful treatment. Have them dressed daily in the Surgery.	
It takes less time to prevent an accident than it does to report it.	It is better to be careful than to be crippled.	It takes less time to learn to do a thing right than it does to explain why you did it wrong.	

Legislative Difficulties.

The question is sometimes asked why makers of, or agents for, machinery are allowed to sell machinery inadequately protected to meet the Factory Act requirements, and the answer, briefly, is : There exists no statutory power, at present, to compel them to do so, but what is being done is, wherever new machinery is found in use in factories with dangerous parts inefficiently protected, to interview its agents or makers and urge the desirability of fencing such parts to meet adequate safety requirements, pointing out that wherever during official inspection such machines are found in use, the employer will be instructed that, from the official safety point of view, they disclose defective conditions which must be remedied. This sometimes has the desired effect on the seller, but others demur (*a*) on the ground of the additional expense involved; (*b*) some employers prefer to provide their own guards; (*c*) that as agents for such machines manufactured abroad (principally America) their powers are limited.

Need of Signalling Systems.

Another very important step taken by the Home Office is to call conferences from time to time with the accredited representatives of employers, employed, and expert inspectors of factories in certain important industries where voluntary agreements are arrived at, as to what parts of their machinery should be fenced, the methods of fencing, together with other questions likely to effect the safety and welfare of the worker—*i.e.*, temperature, ventilation, etc. This is being followed up by the publication of concise explanations in illustrated pamphlets. This is a most praiseworthy development; for "he who runs may read," thereby standardising uniformity of safety conditions and their administration. One important factor in the domain of safety deserving of development is a more efficient method of signalling between two or more persons working in conjunction with, but each independent of, the other; as frequent accidents occur owing to misunderstandings, often due to noisy surroundings, restricted view by, and of, machinery, and which could be largely overcome by the intelligent use of signal lights. Here is an example :—

An Example of Protection.

Two operators are working at a double crank "Bliss" two-man press, one at the back, the other at the front, and the latter operates the lever which works the press, the device herein described being a signalling apparatus from the operator at the back that the material is in position, and ready for the action of the press.

The device consists of two flush type spring push-buttons set at a convenient position within the operator's reach, and at such a distance as to compel the operator to use both hands. The action of pressing the switches starts an electric current which operates a signal lamp, but first of all passes through a solenoid, which, by magnetic action, withdraws the safety pin from the press operating lever. The press then returns to the normal position by mechanical means which is integral with the operating mechanism of the press, and as it does so, the solenoid pin is forced back to its original position by a spring strong enough for the purpose, but not too strong to resist unduly the magnetic action of the solenoid.

Two points have been found by close observation to be necessary to prevent mischievous interference with the safe working of this device: one is that the push switches be of the flush spring type to stop one or both from being locked in the "ON" position; and the solenoid must be encased to prevent the pin being trapped back in such a position as to leave the lever open. The above excellent device was the outcome of an accident by which the operator at the back lost a hand, through the operator at the front of the press *imagining* he had seen the signal light and starting the press whilst the injured man's hands were in a dangerous position.

Many accidents occur during loading and unloading vessels owing to inefficient signalling, etc. These dangers can be largely overcome by the mechanical device illustrated in Fig. 3.

Fig. 3.—Driving a Crane in Safety and Security.

A Device for Safe Unloading.

By this method of control it is possible for the operator to leave the crane cabin and control the operation of the crane from any part of the ship or dock by means of a small portable master controller, which he can easily carry from place to place. When working from the hatchway, the driver has a better view of his work throughout the whole range than if he is up in the crane cabin and is consequently not so dependent on the signals of other people. This is especially useful when drawing cargo from spaces in the hold beyond the hatchway opening and also in swinging goods into these positions. This better view makes the operation so much safer for the man in the hold. It has also the additional advantage of saving the wages of a signaller. There is another point which is specially important at night time, and that is the comparative danger to a man ascending a crane, and especially some very large cranes, when used in the dark. This is of special importance where a man may require to work one out of two or more cranes at various periods in the night.

There is also the matter of comfort of the operator involved, as it is found that most crane cabins are very draughty and require to be heated, and many operators would prefer to work in the cold with a coat in the open air than in a heated but draughty cabin.

Hoist Protection.

Notwithstanding improved methods of protecting the hoist-well itself, the number and seriousness of hoist accidents still continue to be so alarming that it has been found desirable—and even necessary—to try and standardise certain precautionary measures of additional safety, and a pamphlet thereon recently issued by the Home Office states "a large number of accidents are caused by crushes between the travelling cage and door lintels or other projections in the hoist well. *Practically the whole of these would be prevented by fitting a collapsible*

gate on the cage itself. In addition each doorway should be provided with a gate or door fitted flush to the inside of the 'well,' so constructed that (1) it cannot be opened until *the cage is at rest* opposite to that floor or landing, and (2) the cage cannot be moved away until *the door or gate is closed and fastened.*"

This recommendation is essentially an unique opportunity for electrical equipment to come into its own, as thereby the use of hoists can be made practically "foolproof," as an auto locking device can be, and is being, applied to electrically driven hoists, whereby the electric circuit between the cage and protecting gates or doors become operative or broken by the arrival at, or departure from, any floor. In addition, by a mechanical interlock between the gate of the cage and the door, the latter can only be opened when the cage is opposite the door and the cage can only be moved when the door is closed. At first difficulties arose in applying the arrangement to belt-driven and hydraulic hoists, but "necessity is the mother of invention," and these obstacles are now mainly overcome. In one such instance not only are the Home Office recommendations referred to above carried out, but when the gates are properly closed, and not till then, a lamp in the cage becomes automatically alight, and continues so whilst the cage is in motion and the doors or gates remain closed.

Cranes and Accidents.

In proportion to the numbers employed on cranes, the percentage of accidents—mostly serious or fatal—is far too high. There are invariably three types: (1) overhead, (2) runway, (3) overhead, but running on ground rails; and risks may be classified generally as (*a*) falls of persons, (*b*) falls of material, (*c*) contact with other workmen on floor, (*d*) electrical.

Falls of persons in the hand operated crane occur mainly owing to insufficient fencing of the hoisting platform or faulty means of access; in the electrically driven type the same causes operate. Where repairs have to be carried out to the overhead structure a safe platform or other means should be provided. Occasionally, through some failure, the crane cannot be brought back to the usual point, hence means must be at hand whereby the operator can descend safely—*i.e.*, by ladders at intervals, or a rope ladder in the cabin.

Falls of Material are mainly due to (*a*) failure of machine (either faulty design, overloading, or wear and tear); (*b*) failure of chains, slings or ropes; (*c*) contact of hoist material with fixtures; (*d*) improper slinging; (*e*) careless working of crane. Therefore, plant must be properly designed with adequate factors of safety; stop blocks fitted at ends; maximum safe load clearly marked on cranes; structure, chains, ropes, etc., be periodically examined by a competent person; faulty wire ropes be repaired or replaced, and chains annealed; material be loaded under proper supervision; the crane be in charge of an experienced and careful person with a proper system of signals with the ground.

Contact with workmen on the ground may occur either owing to improper handling of the crane, whereby workmen are struck by the load, or, in a gantry crane with floor rails, by crushes between the moving framework of the crane and fixed structures in the building; where this is likely to occur, curved shields on the principle of the cow-catcher should be fitted, so that persons are pushed out of danger. All cranes should be fitted with a distinct form of sound signal—preferably of a continuous type. This is especially important where the workplace is noisy.

Electrical Crane Dangers.

Electrically, the danger on cranes is from shock, which may or may not give rise to a fall; it is therefore important that the cabin switch-board be of a safe type, and switches for various operations be plainly marked. Overhead feed wires should be protected near all parts to which access may be required, and wires along walls from which power is supplied be protected at those points which are to be crossed when the operator has to enter or leave the cabin—a shield fitted so as to run with the crane acts effectually as a protection.

Fire Precautions.

Prompt and efficient means for notifying an outbreak or alarm of fire are a valuable asset to employers and property owners—quite apart from the more important consideration of saving life—hence it is very important that premises be fitted with an electrical device whereby danger signals by lights or bells, or both, can be immediately communicated as a distinctive fire alarm. The necessity for some such arrangement was emphasised recently by an outbreak of fire in a factory in a large city resulting in the loss of five lives, and a miraculous escape of 30 other persons. The fire broke out at 6.30 p.m. (October) on the first floor of a four-storey building, and at the time 35 persons were in the top workroom, but before they could be communicated with, the internal staircase was full of smoke, and efforts to make the danger known to them by persons outside were unavailing, so that by the time the alarm could be given the outside iron staircase was enveloped in flames and escape practically cut off. An efficient system of signalling by means of a substantial bell, operated from, say, the time lodge, would have given ample warning to the occupants of the room that danger was about. The following is an excellent arrangement in operation at a company's large premises for calling appointed firemen from the respective parts of the building to the works' chief fire station, wherein are two sets of accumulators of 15 V each, charged from the electrical supply mains. These accumulators control seventeen 6 in. bells, distributed over the main staircases of six large seven-storey buildings. They are fixed in position on the staircases so that firemen employed can hear them at any time they are required, the wires being run from each bell to accumulators and control pushes in Chief Fire Station. A push-button is also fixed in each block of buildings in a small fire box with glass front, marked "Fire," so that warning can be given to Chief Fire Station in case any of these buildings get on fire; the chief fireman can then ring all firemen from other sections of the premises. A wire is taken from each push-button to a bell in the Chief Fire Station, the chief fireman from the station can press a button and call any section of the men from any single building, or, by pulling down the lever,

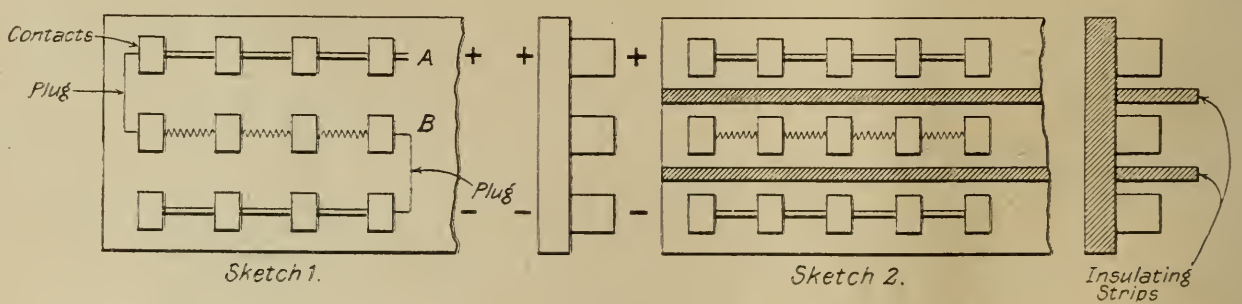

Fig. 4.

which connects all the push-buttons, he can call all men together at the same time from the whole six blocks of premises.

Electrical Accidents in Testing Departments.

Electrical accidents in testing departments may be due to the three following causes :—

A.—Testers' own carelessness—i.e. :

1. Burn or shock due to interfering with connections on switchboard or machine on test without making circuits dead.

2. Burn due to tester shorting mains with one piece of wire owing to not making certain that the voltmeter switch is in correct position for reading a high voltage.

3. Burn or shock which may be caused by paralleling a d.c. machine on the line and tester not carefully testing that there are no volts across switch before closing it.

B.—Bad arrangement of testing sets and materials used—i.e. :

1. Burn on hands or face owing to the fuses on the test switchboard being in too close proximity to the switch.

2. Burn on hand due to plugging up a resistance frame and an arc extending from plug to the opposite pole. Arc may occur across A B, see Fig. 4, Sketch 1.

This can be prevented by placing an insulating strip between the rows of contacts, and thus prevent arcs. See Fig. 4, Sketch 2.

3. Various firms have different methods of dealing with shock prevention on H.T. flashing circuits, and each may have its defect ; but I will deal with the one only with which I am familiar.

In the standard flash test up to 2 000 V the H.T. circuit is supplied by means of a small motor-alternator through a transformer, one pole of which is earthed and the other pole run through H.T. wire down the Test Department, and is tapped off at various points to a guarded hook.

The H.T. lead consists of a special H.T. cab-tyred cable (capable of standing 20 000 V) with specially prepared connectors at each end, and consequently quite safe to use. Care is taken that only one flashing lead is in use at once, and arrangements are made so that the H.T. line is dead when not in use. Thus if a Test Department is arranged conveniently and all testing circuits are entirely separate and controlled by switches and breakers, so as to make it impossible for a tester to obtain shock, etc., from another circuit close at hand, and also all testing leads to be clear of any passage, then the risk of accidents is very much minimised.

First-aid Methods.

Notwithstanding the adoption of efficient provisions to ensure safety, accidents will continue to occur from a variety of unforeseen or unpreventable causes, lack of reasonable care, inadequate supervision, etc., and to deal therewith there should be provided means to enable treatment of injuries sustained during work. And the first essential is a first-aid box (or boxes) suitably placed in the works, equipped, maintained and used in accordance with the requirements needed for each trade dealt with in various Welfare Orders issued from time to time by the Secretary of State.

In certain industries where 500 persons and upwards are employed this provision should be supplemented by an ambulance room suitably placed—in charge of a qualified nurse or other person trained in first-aid, who should be readily available during working hours—and contain at least :—

(i) A glazed sink with hot and cold water always available.
(ii) A table with a smooth top.
(iii) Means of sterilising instruments.
(iv) A supply of suitable dressings, bandages and splints.
(v) A couch.
(vi) A stretcher.

Accidents arising from electric shock require special treatment apart from these provisions, the most important being the immediate application of artificial respiration as a means of resuscitation in cases of apparent death, to be resorted to *at once*, and persevered with for at least two hours, or until the patient revives. Here again it is quite impossible to go into details, and readers are referred to Home Office recommendations thereon. It has also been found desirable by some electrical authorities—to avoid any possibility of misunderstanding verbal instructions—that, before commencing work on any high tension system, the erector, foreman or jointer in charge shall receive from the engineer supervising the work a form as follows :—

To the Foreman-in-charge,
..... Cable.
Time .....
The above cable is dead and earthed, and work can now be started on this line.
Signed .....
Engineer-in-charge, Power Station.

Then when the work is completed the preson in charge shall report :
To the Engineer-in-charge at the Power Station,
or
Senior Operation Engineer,
..... Cable.
Time .....
All men are clear of the above cable.
Signed .....
Mains Department.
Date.....

Conclusion.

Prejudice against new developments, such as "Safety First," dies hard, and difficulties are not so easily overcome. Some day—soon it is hoped—the long contemplated provision and equipment of what has been termed a "Safety Museum" will be established in this country on the lines, it may be, of those in America and on the Continent, whereby can be made known to our manufacturers the adaptation and uses of safety apparatus and the details of organisations in this and other countries that have more or less grappled with the problem of accident prevention. The American museum of safety holds a special charter of incorporation granted by the Assembly and Senate of the State as follows :—"The objects of the Corporation hereby created are to study and promote means and methods of safety and sanitation and the application thereof to any and all public or private occupiers whatsoever, and of advancing knowledge of kindred subjects ; and to that end to establish and maintain a museum, library and laboratories and their branches, wherein all matters, methods, and means for improving the general condition of the people as to their safety and health may be studied, tested and promoted with a view to lessening the number of casualties and avoiding the causes of physical suffering and of premature death ; and to disseminate the results of such study, researches and publication." *

As this article commenced by quoting Mr. Gladstone, with another quotation from him it may fitly conclude : "Apart from his agreement with his employer, each man should have a contract with himself, always and in all things to do the very best he can" ; for only by the loyal co-operation of the worker to make the best use of the means provided by his employer can "Safety First in Factories" be translated from the visionary dreams of idealists into the new awakening of an accomplished reality.

---

* In opening the Paris Museum of Safety, the then President of the French Republic (President Loubet) said :—"Never does one appeal in vain in France when it is a question of social usefulness. Thus the Government of the Republic is associated with this museum. How could it be otherwise ? For this work, protecting and lengthening the life and labour of our workmen, is a most valuable asset to our country, and you may be sure that whenever a work of this nature is presented for governmental consideration it will support it with grants of money."

Tariffs for the Sale of Electrical Energy.

By JULIUS FRITH, M.Sc., M.I.E.E., M.Cons.E.

Electrical energy is so essentially unlike anything else which is bought and sold that the principles involved require very special study. In the case of no other commodity do the capital charges involved play so important a *role*. This is mainly due to the fact that storage of electrical energy on any large scale is hardly practicable, and, therefore, that the energy has to be made as and when required.

Roughly, if the total cost of a unit is, say, one penny, one halfpenny of this is for capital costs and only one-half of the remainder, or one farthing, is for coal. This gives to the "load factor" of the demand a preponderating effect which does not obtain in any other commercial transaction.

Object of a Tariff.

Before deciding how to embody these conditions into a "tariff" it is necessary to settle clearly what the tariff is to accomplish, and here a difference which is often lost sight of is brought to light, namely, whether the supply is given by a company or by a municipality.

In the first case the company manager is appointed by the shareholders to earn as good a return on their money as possible, under certain statutory limitations. The prices charged should be as high as possible consistent with not imperilling the securing of additional custom. The division of the contribution levied from the different types of consumers need not necessarily bear any relation to what each consumer costs to supply; it might conceivably be good business to charge a uniform rate to all comers, hoping to make up on the swings what was lost on the roundabouts. The price asked, in other words, is limited only by the will and ability to pay.

Municipal Trading.

The case, however, is very different with the municipal undertaking. Here the ratepayers, for their own ends, have put up a station with money borrowed on the security of the rates. There should be no question here of making a profit, and each consumer should contribute to the joint expense as far as humanly possible, in proportion to what his supply costs the community.

Two Systems of Charging Permissible.

It is seen at once that these two cases may, quite rightly, lead to very different systems of charging for electrical energy. There is one rule, however, to which *all* successful systems should conform. It is that the tariff should be simple and easily understood. The great majority of tariffs at present offered are far too complicated, giving the impression of being manufactured by a mathematician rather than by a business man. It is essential that the prospective consumer shall be able with some certainty to predict what his bill for energy will come to.

After this first principle has been established the tariffs suitable for the two types of supply may be grouped under the following requirements:—

For companies the consumer who pays best should be most encouraged, and the consumers from whom it is next to impossible to derive a profit, should be made to pay as much as an all-wise Government will allow. The aim of the tariff should not be so much to make each individual consumer pay as to make the concern as a whole pay.

For *municipally owned concerns* the aim of the tariff should be, as before said, to make the punishment fit the crime and make each consumer pay what it costs to supply him.

Determining the Cost of Supply.

When these two are compared in this way it is seen that each has an interest in knowing what a certain supply actually costs. Now this is much more difficult to determine than would appear at first sight, for although it is comparatively easy to find out what the cost of the supply is as a whole and how the cost per unit is affected by the load factor of the station as a whole, it is far from easy to see how the connection of any *new* load will affect this cost.

It is desirable that those consumers whose demand lessens the load factor of the station should in some way contribute on a higher scale to the expenses than those whose demand increases the load factor. It is, however, a very difficult thing to devise a tariff which will effect this; for instance, any consumer who takes energy from the station at however low a load factor, but who does not increase the maximum load on the station, increases the station's load factor, but if he does increase the total maximum demand on the station and does not increase the average load by an equal ratio, then his load reduces the load factor of the station as a whole.

It is thus seen that any particular load that may be offered to the station is not good or bad in itself, but only as it differs from or approximates to that of the majority of the other consumers already connected.

Need of Diversity.

It is thus seen that a station stands to gain by the diversity of the individual demands, for its load factor may be increased by a demand at a lower load factor than its own, but cannot be decreased by a load at a higher load factor, even if the maximum of the two coincide in point of time.

Two distinct attempts are being tried at present to meet this; the first is a restricted hour tariff which offers energy at a price free of all capital charges except those of the new service cables, etc., required, to those consumers who do not under any circumstances increase the maximum load on the station. This condition is often enforced by the use of a time switch. The second is a method of charging on the load factor of the new demand, irrespective of its relation to and effect on the load factor of the station as a whole.

In the light of what has gone before, the *justice* of this latter is more than doubtful—*e.g.*, two new consumers may be connected and by reason of the equality of their load factors may be charged equally whilst one may not add anything to the maximum station load, and so be supplied at little more than the cost of coal, whilst the second may involve the concern in capital charges equal to the maximum demand of the new load.

Justice and Experience.

What is not always just may nevertheless sometimes be expedient, and the mixed tariff of so much per annum per kW of maximum demand plus so much per unit taken meets the average case of a demand for industrial purposes fairly well. In some cases the kVA is substituted for the kW of maximum demand, with, however, only a show of justice, as the capital charges are perhaps half way between the voltamperes and the watts.

Supply undertakings are becoming more alive to the cost to themselves of carrying about magnetizing current for their consumers' devices, free of cost, and are one and all considering how the question of low power factor can best be dealt with. As mentioned above, some authorities are making the fixed part of their tariff proportional to the kVA instead of the kW of the maximum demand. This appears to be as unfair to the consumer as the other is to the supply authority. This fixed charge is to cover the capital cost involved in being ready to give a supply if called upon to do so. Now the cost of buildings, steam-raising plant, coal and ash-handling plant, as well as that of the prime mover is unaffected by the power factor and depends on the kW alone.

Other concerns increase the whole quarterly account by a percentage which increases as the power factor decreases. It is, however, very difficult to say what the average power factor of an installation is; this *could* be found by comparing the readings of integrating watt-hour and volt-ampere-hour meters.

It is *most* desirable that some uniformity should be arrived at between all the supply authorities in regard to this matter, as well as in the other parts of the tariff, as there are at present in use about three times as many tariffs as there are supply undertakings in the country.

Modern Industrial Organisation.*

By HUGO HIRST, M.I.E.E.

Industry may be defined as the combined efforts of brain, labour, and capital to create values from raw materials. The brain, because it directs the activities of the body, comes first. Capital is the accumulation of savings produced by the efforts of brain and labour.

Among Government Departments, now being so keenly criticised, the Post Office alone seems to resemble more closely a business concern than any other Government Department, but even here the possession of a monopoly eliminates many of the difficulties inherent in competitive businesses. In industry questions of mutual interest arising between purchaser and seller cannot be settled by regulations imposed by either side. Every point has to be settled diplomatically by persuasion or by compromise. It is necessary, however, to bear in mind the fundamental difference between an industrial and a Government organisation. The Government has to render services to the community, the value of which cannot be expressed in money, and its departments are not in most cases limited by the time factor. Industry has to render services, which must be expressed in terms of £. s. d., the result being obtained within a limited period. The civil service organisation is framed to last for long periods, and absence of flexibility may be an advantage.

Individualism in Industry.

It will be clear, therefore, that in industrial organisations the individual must receive more latitude than in Government Departments. Industry is in a constant state of evolution, and changes due to fashion, competition from other countries, financial conditions, inventions and many other circumstances may produce sudden stoppages or changes. It is essential that an industrial organisation should be pliable, simple, human and personal, rather than rigid and anonymous. The consequence of this is that men engaged in industry must be ambitious and with strong will-power and personality. Such qualities would be a handicap to a civil servant, for this service seems to require men of high integrity and education, but with capacity for self-effacement. They must suppress the spirit of risk and adventure so much appreciated in industrial life. Examinations may conceivably be used for selecting Government servants, and a system of promotion by seniority might be arranged, but no examinations could be used to select men required for industry: character, initiative, energy, enterprise, decision, and all the many factors in personality count as much in an industrial worker as his accomplishments.

The Organisation of the General Electric Co.

Experience has taught us that the only safe basis of organisation is not the system, but the human factor that controls the system in this industrial undertaking. The General Electric Company has some fourteen factories, each belonging to a different industry in different parts of the country, and thirty or forty sales organisations in the United Kingdom, and some thirty others overseas, all managed independently. The relations between management and staff, between management and workpeople, the relation between a company and its customers, and authorities or public bodies, its attitude towards competition in this and every other country, its share in the development of industry, should be conducted everywhere on the same lines. This can only be accomplished by having placed at the head of each factory, each branch, each enterprise, a man of good character, fully conversant with the policy and the mentality of the chiefs of the concern, and being a faithful interpreter of their wishes and ideals. Such men cannot be found from without; they can only be created by a process of education from within. Education of one's staff as regards business policy and business principles is one of the great problems of industrial organisation.

Rising to the Top.

I have, in the course of years, brought on a number of men and placed them at the head of works, at the head of branches at home and overseas, or at the head of companies which we control. Many of them started at 10s. to 20s. per week and have risen in course of time to high and responsible positions, with emoluments ranging from £1 500 to over £5 000 per annum. We leave it to them to work the enterprise for which they are selected, putting at their disposal trained experts both on business and technical sides, assisting them with publicity and propaganda, catalogues and general sales regulations. We give them the fullest power within the limits of the capital put at their disposal—power equal to that commanded by ownership. Except the annual audit, there is no system of control and inspection. They have, vis-à-vis to customers and staff, the same authority as if they were principals. Their limitations are only known to themselves and the Board.

In the 35 years of my experience, I know of no single instance where this confidence has been misplaced, though I do not say every one has been successful.

The yearly balance sheet and certain statistics bring out the weaknesses of each organisation and lead to discussions, alterations and improvements. I therefore can describe our system as management by personal representation or substitutes, and yet there is a very real control and direction from above.

The system that we are applying is particularly suitable for English industrial concerns. In industrial concerns in Germany and America more rigid organisations exist. The system of schools and Universities in those countries is more standardised, and it is more possible to find a number of men of similar qualifications that can replace with each other. In this country you can scarcely find two men with the same qualifications; you must let each work in a manner that he can get the best out of himself.

Some Fundamental Industrial Safeguards.

I now wish to dilate on a number of points which will explain how it is that an organisation so apparently loosely knit together can still act as one unit, carry out one policy, and how irregularities and risks are limited.

There are a few fundamental safeguards, such as :—

(1) Limitation of the capital put at the disposal of the different undertakings.

(2) Separate finance for expenses and trading.

(3) Head office control of all trading finance and capital expenditure.

Apart from these, all interference, all direction emanating from head office, is suggested by watchfulness of balance sheet and monthly statistics of expenses and sales. It is little realised, even by the subordinates of one's own organisation, what an eloquent document a balance sheet is, what it tells the chief of a concern who knows his business. The actual profits made are by no means the determining factor in the eyes of the chief whether a concern is well managed or not.

The branch manager producing a document thinks all the items are peculiar to his branch or district; the man at the head, reviewing scores of these documents year after year, has learnt that economic laws are governing them like everything else. For instance, assuming that a manager sends me his balance sheet, what are some of the critical points to be considered?

Critical Points in the Balance Sheet.

(1) *Sales.*—Is the total turnover which he does a reasonable proportion of the possible sales in the territory, bearing in mind the relative position of my company with competition in the country?

(2) *Stock.*—Is his stock in the right proportion to sales?

(3) *Accounts.*—Are his outstanding accounts in proportion to his turnover?

(4) *Expenses.*—Are the expenses in the right ratio to turnover? What is the ratio of salaries to other expenses, etc.?

It can be elaborated in a very few words how an intelligent study of these figures leads to just appreciation of the merits or failings of the management.

More difficult is the criticism of works accounts, owing to the factor of changing prices of raw materials and the frequent change of patterns, designs and methods of production which influence works balance sheets, which is in some measure mitigated by fixing maximum and minimum stocks. A specific indication in a works balance sheet is the ratio of output to productive and non-productive wages, etc., etc. But generally it is expected of the managing head that he should have ever present in his mind all that is happening so that he can form a correct picture.

* This article is based on an address delivered to the Association of Civil Servants. Had the audience been from a less limited field some of the comments would have been different.

The Captain of Industry.

It is little known what volume of high pressure work and intensity of thought are expected from a modern industrial chief, frequently called "captain of industry." His duties are ever so much more complicated than those of the mere merchant or distributor. He has to deal with all the problems of the merchant so far as the distribution of his goods throughout the world is concerned, but whilst the merchant has the whole world open to him to buy in the cheapest market, the industrialist has to produce under conditions prevailing in his country in a manner to enable him to compete against the cheapest market. It is for him to judge the possible market for his wares and to lay out his works accordingly. We have no reliable census of production in this country, and a mistake made by him in this respect is often the fundamental cause for eventual ruin. It depends on his judgment whether he succeeds in selecting the best scientists, the best technical men, the best works managers and the best commercial people. It is up to him so to co-ordinate them that there is the least amount of friction, and yet in an industrial concern you have not only to reckon with petty jealousies like everywhere else, but there is the fundamental jealousy or fight for supremacy between the commercial and technical elements. He cannot possibly know all the details of his business, but he must be a man of high integrity and education so as to understand the intricate scientific, technical and commercial problems which are put up to him for judgment and decision when experts differ, which is all too frequent. Research, development, production, sales and distribution must be correctly co-ordinated in his programme. He must keep himself informed of all progress in his industry, of all progress in methods of production, of all new inventions affecting his interests, of activities of competition all the world over. He should know something of the raw materials and the purchasing capacity of each country, with which should be combined a knowledge of the political, social and economic conditions in these countries. It is for him constantly to encourage and inspire the men under him. He must endeavour by personal attainments to merit their regard and, by unbending and mixing with them on the right occasion and in the right manner, to merit their friendship and confidence. Above all, it is for him to bring home to his people the national need for production. He must have a good understanding of the principles of law and finance and should take every opportunity to offer his valuable experience to the country and those that rule it.

No Regulations or Agreements.

Under normal conditions, it is my duty to direct an organisation of from 15 000 to 20 000 people. In industry we have no army regulations that enable us to command and that forbid subordinates to ask why. We have no common great danger which spurs us on to united effort: united effort is only possible if those you lead believe in your high ideals, your integrity, fairness and correctness in every detail of your actions. To my knowledge not one of the principal members of our whole organisation has an agreement. Weekly or monthly servants have been with us for a generation and do not worry about their future.

His task, which has ever been difficult, is not lightened in modern times by the fact that the majority of his men have not only him but many others as masters. All his decisions must be quick, otherwise he loses opportunities and, though he may be subject to a board, unless the board give him the fullest confidence—including the right to make mistakes—so that he can act independently and quickly, he cannot make a success of the enterprise in the face of the world's competition.

Price of Greenock Tramway Current.

At last meeting of Greenock Corporation, Bailie N. M. Brown, convener of the Electricity Committee, announced that they had RECEIVED THE FINAL AWARD in the arbitration concerning the charge for electricity for traction purposes. The local Tramways Company appealed to the arbitrator against his first finding, but no alteration had been made. Under the award the Corporation obtained an additional £2 811 and a proportionate increase for the next four years. Under the old scale the first 500 000 units was at 1½d. per unit, the next 150 000 1d., and all beyond 0·85d. per unit. The new scale was 2·4d., 1·85d., and 1·03d. respectively, all subject to a coal clause. Putting it shortly, and taking the average price of coal at 30s. this year, the Corporation would (he said) receive £1 400 more under the award than under the old scale. They also got all expenses in the first part of the arbitration and half of the latter. He thought the Committee was to be congratulated on the result, and thanks were also due to their legal and engineering advisers.

Electric Traction in Chile.

For the last ten years the foreign trade of CHILE has been mainly with the British Empire, the United States and Germany, and though the latter lost her trade to the Americans during the war, she has again entered the Chilian market, and the Commercial Secretary at Santiago (Mr. W. F. V. Scott) thinks that British manufacturers have more to fear from German than from American competition. The coal market prospects continue depressed, and the electrification of the first zone of the State Railways, of the Iquique Nitrate and Chilian Transandine Railways, and the completion of the power plant of the Compania Nacional de Fuerza Electrica will effect considerable economies in the consumption of coal, and further affect the situation.

During the year the Westinghouse Electric International Company secured what is said to be the largest electric traction scheme executed by any American firm abroad. The contract is for the conversion of the first zone of the Chilian State Railways (between Valparaiso and Santiago) at a cost, including locomotives and all material required, of $5 677 947.71 (U.S.) and $2 319 707.56 (Chilian). Power will be supplied by the Compañía Chilena de Electricidad, Ltda., at 4 centavos gold (0·72d.) per kWh. The work has already been commenced, and a special commission of Chilian engineers has left for the United States of America to take delivery of the locomotives and other material purchased.

A Political Hitch.

The Iquique Nitrate Railways concession had been renewed by a Ministerial Decree for 50 years, and the company was empowered to raise its tariffs 35 per cent., in consideration of which the railway agreed to electrify the system and repair certain deficiencies in the service. The decree has been pronounced unconstitutional, having been signed without the consent of Congress, and has consequently been rescinded. The matter will be brought up for reconsideration at a future date, and it is believed that it will be passed.

The Chilian Government has agreed to the fusion of the Chilian Transandine Railway with the Argentine Transandine Railway. It is proposed to make such improvements on this line as will make stoppage during the winter by snow almost impossible, as well as to electrify the major part of the line. During the negotiations with the Chilian Government, estimates were required for the electrification, and help was sought from the representatives of some British firms capable of undertaking the work, but none was found and recourse had to be had to the International Electric Company of America. The railway will require to purchase considerable quantities of rolling stock, machinery, etc., at an early date.

Several small railway lines have been constructed, and some are in course of completion. The most important future work is the construction of a new line between Valparaiso and Santiago, passing through Casablanca and Curacaví, with a short branch to Talagante, which will bring the principal port twenty-six miles nearer the capital, the tortuous line at present used, and now being electrified, is 130·2 miles long. Owing to lack of funds, the railway will have to be constructed under concession. The line is to be worked by steam or electric equipment. The concession is to lapse on the termination of the amortization, but may be terminated earlier by the payment of the outstanding capital plus 10 per cent.

Electricity Supply and Tramways.

The Chilian Electric Tramway and Light Co., Ltd., of Santiago, which was handed over to the Receiver of Enemy Firms during the war, and in which an English firm acquired the controlling interest, has been reformed into the Compañía Chilena de Electricidad Limitada, with an increased capital of £12 000 000, and has also acquired the controlling interest in the recently formed Chilian Compañía Nacional de Fuerza Eléctrica, whose original capital was £800 000, now increased to £3 000 000. A large power plant is being erected to utilise waterfalls within 30 miles of Santiago, which is anticipated to be in operation in July next. Distributing stations will be erected for utilising the power over a large radius round Santiago, and beyond lighting the Capital and running its tram service, the contract has already been secured for running the first zone of the State Railway between Santiago and Valparaiso. Other contracts likely to be secured are the running of the Transandine Railway, shortly to be electrified, Valparaiso Port Works, and a large number of industries in the zone covered.

The Madrid combination of Spanish and German interests took over the Valparaiso tramway undertakings of the Deutsche Ueberseeische Electricitäts Gesellschaft in March, 1921. A small electric tramway service was started during this year at the town of Temuco, and permission was requested in November, 1921, to instal a similar service in Valdivia.

Submarine and Radio Telegraphy.

Interest is being taken in the project for laying a submarine cable connecting Italy with South America. The cable will start from Fiumicino, in Italy, and run to the Argentine, Uruguay and Brazil, and in Europe have branches to the Near East, the Balkan States, Spain and North Africa. It is proposed to connect the Pacific Coast to Buenos Aires by direct telegraph line.

The Chilian Government concluded a contract in October, 1921, with the Siemens-Schuckert Co. for the erection of eleven radio telegraph stations at Santiago, Valparaiso and Punta Arenas (all capable of communicating with Buenos Aires) and at Iquique, Antofagasta, Taltal, Tocopilla, Caldera, Concepción Valdivia and Chiloé, with a maximum radius of 1 550 miles. The contract price is $1 385 000, and the Telefunken system will be installed.

The Future of Industrial Research.

By F. PEAKE SEXTON.

The question of industrial research has been much to the fore since the war demonstrated what could be done within a short period by well organised work. It may be truly said that the valour and courage of the troops would have been wasted but for the continued success of our hastily organised research.

Many of the largest and most progressive firms in the country began to create research departments directly after the termination of the Armistice, doubtless thinking that what had so profited the country could in an equal manner profit commerce. Funds were plentiful, the excess profits tax was still in force and private enterprise stood to gain much for the smallest expenditure, but unfortunately the conditions soon changed with the development of labour troubles and financial uncertainty. Then arose the real test of the progressiveness of our manufacturers, and sad to relate many were induced to abandon their pioneer work.

Not a Simple Question.

The question of research laboratories is not so simple as might be inferred or, naturally, all firms would have adopted or dispensed with them. It is not fair to say, as some scientists do, that because some firms have not adopted research laboratories they are backward, out of date, or unprogressive, for the mere success of a business implies considerable ability from the management, even though, naturally, errors may be made. Hence we should carefully search for the reason in many, in the very many, cases of the absence or understaffing of the technical departments. The commercial management looks with invariable disfavour on any department that is not either directly engaged in production or the sale of the trading commodity. Office systems were at one time regarded as wasteful luxuries only to be indulged in by the most successful, yet now success beyond the "one-man business level" is impossible without the highest organisation. In the same way the question of industrial research is passing through this stage until it will ultimately reach the level of a business necessity.

The Financial Aspect.

Nevertheless, the engineer or scientist, who is pressing for the universal adoption of works laboratories, must remember that he is proposing a heavy expenditure on laboratory, apparatus and personnel that can only with profit be borne by the larger firms. Although the result would help even the smallest manufacturer, in his case, in all probability, the gain would not pay for the expenditure. Commerce being entirely financed for the production of profit does not wish to take risks, thus accounting in the past for the gross neglect of technical research.

The present trend of progress is indicated by the development of trade combinations, acting jointly in the provision of a research laboratory and its endowment with maintenance funds. The results of the work done there are open only to the supporting firms, which also should have the right of having tests made on their behalf either free or at a nominal charge. These tests should cover the testing of raw material, the finished product or of proposed new methods.

The Importance of Trained Personnel.

The personnel of the laboratory is the most important item, for here are not required men of great inventive genius, but rather men of great practical care and thoroughness in the testing of details. The work is hard and exacting and not likely to yield that glory sometimes obtained by research on the purely scientific side. On the other hand, there is the great satisfaction of knowing that the work is being immediately applied either in the saving of raw materials by the perfection of a process, or in the production of new materials.

A Lesson from Germany.

We can even now learn something from Germany, which in pre-war times was heavily involved in industrial research. As an example a glass works may be cited where independent of theoretical considerations the effect of varying proportions of minerals in glass was tabulated and correlated by a staff of observers and experimenters. Here were found a number of small furnaces and testing plants so that each experimenter worked on his special section, the joint results being interpreted by another department

The staff need not have the inventive genius beforementioned, be they assistants or chief, and while in the former case thoroughness and skill are required, in the latter to these must be added great clearness of vision and organising ability. Although technical ability is not mentioned, it can be taken for granted that a good technical training is absolutely necessary for success in work of this nature.

If a laboratory be founded on these lines, and well equipped with personnel and apparatus, success and great profit are assured, provided that there is whole-hearted co-operation between all concerned.

The staff should work together with the directors as one man with the one idea of furthering the industry. Too often valuable progress is retarded by internal friction, sometimes inter-staff, sometimes between the staff and directors. The fault is often on both sides and is due to lack of firmness in the control and a certain natural reluctance to take a firm course. There should be mutual consideration on all points and where possible joint discussion and consideration of grievances, but if friction develops, then it is the duty of the director to clear his staff of it, or if he fails the management should not hesitate to act. Drastic action is distasteful to all but in circumstances it is necessary, as otherwise the whole efficiency is likely to be lost. There are many cases of whole institutions being ruined from lack of control.

America *v.* Europe.

By A. P. M. FLEMING.

It is notorious that the greater the odds against which men have to struggle the greater will be their efforts to overcome them. Much of the fear the Allies have of future German trade competition arises from the strength Germany will gain in fighting to regain her place. A somewhat similar thought was evidently in the mind of Mr. D. T. Farnham, an American efficiency engineer, who visited Europe in 1920 with the object of obtaining a first-hand impression of the strides which industry made during the war under the tremendous stimulus of war-time conditions, the result of which has recently been published for the benefit of his countrymen.*

Raw Materials and Industry.

The importance of surveys of this character can scarcely be exaggerated. In the initial stages of growth the location of industries in any particular country was determined not merely by the genius of its people, but by the presence and appropriate distribution of raw materials. To-day the position is profoundly modified. Due to striking improvements in means of transport and communication, the success of an industry is dependent to a much lesser extent upon the necessary raw materials being found in any particular location. As potential wealth, of course, raw materials are of vast importance, but their distribution is immaterial. On the other hand, it is now recognised that labour is comparatively immobile. Success in industry is therefore becoming increasingly dependent upon the other great factor concerned, the organising and administrative ability of leaders of industry. In an era of world competition the standard of living of people at large, the industrial supremacy—ultimately the political supremacy—of an industrial nation depends upon its economy of manufacture. To a much greater extent than is commonly supposed the future of industrial countries lies in the hands of its industrial leaders. Comparisons between the principal manufacturing countries, Great Britain, U.S.A., Germany, France, Switzerland, Italy, Japan, Belgium, assume therefore a considerable importance, particularly with regard to their methods of organisation and industrial control.

Understanding One Another.

Herein lies the value of Mr. Farnham's attempt, the British precursor of which was Dr. Arthur Shadwell's well-known "Industrial Efficiency." Apart from its direct contribution to management, Mr. Farnham's book should have considerable value in enabling business men on both sides of the Atlantic to understand one another. In Europe only too frequently are American business methods condemned because of the

---

* "America *versus* Europe in Industry," by D. T. Farnham, New York, Ronald Press, 1921, xvii+492 pp. $4.

prevailing American tendency towards advertisement. Even when this is allowed for fully there still remains an enormous amount which Europeans can learn from American energy and enterprise. On the other hand, American business men may be surprised to find how advanced are industrial concerns in Europe. Their ignorance very largely arises from lack of advertisement on this side of the Atlantic, because industry is taken as a normal and everyday affair about which we should no more think of talking than about eating, breathing or sleeping.

Need for More Examination.

It is inevitable that a book covering such a wide field should be to some extent discursive, and American publishers have not been compelled by circumstances to discipline authors with regard to space. Nevertheless, there is matter of considerable interest relating to the personal methods of business leaders in various countries, methods of organisation, labour, factory buildings and management. On the whole, the conclusions drawn with regard to the industrial position in Europe are correct, and we may predict that those responsible for industrial enterprises will in future be more and more compelled to examine what is being done in other countries, for each country will ultimately produce only that which it is most economically fitted to undertake.

The Psychological Effects of the Whitley Councils.

By A MEMBER.

The Whitley system has now been operating in the electricity supply industry for somewhat over two years. Its inauguration and the first year of its life coincided with a very disturbed state so far as labour was concerned. The Industrial Councils had therefore plenty of work to do and it is generally acceded that they did their work well. Now, largely—and indeed mainly—to their good offices, the industry is entering smooth waters. The croaker's opportunity has therefore come, we hear overt or more often veiled criticism, sometimes even a suspicion of back-door intrigue. "What is the good of the Councils?" is the question we hear asked by these ingenious critics.

Now, to answer this question, accepting it as a *bona fide* one, is the object of this article.

The Growth of Mental Intimacy.

The tangible results in the way of codification of wages adjustment to cost of living and so on speak for themselves, so does the "industrial peace" of the years under review. But what is not so obvious, but is equally real and indeed potent for good, is the psychological result. By this we mean the subtle but fundamental change in the whole mental attitude of both sides towards each other. There has been engendered a kind of mental intimacy, so to speak, which makes for mutual understanding. This is a fundamental condition without which there is no chance of "living together." And labour and capital have most certainly got to "live together," and to achieve the fine art of doing so, like man and wife. In each case—the industrial no less than the matrimonial—this can never be achieved by any meticulous settlement of rights and duties and so on. Sir William Mackenzie, in his recent decision in the Industrial Court on the engineering dispute, came to this conclusion, and pointed out that no amount of rigid definition could take the place of good sense and good will, or in other words, of a mutual and amicable understanding. But it is just the latter that the Industrial Councils in the electricity supply industry have, to a very great measure, achieved. The scheduling of wages and conditions of working and so forth are excellent so far as they go, but their real value is only to be assessed in conjunction with the potent concomitant of good will and understanding which is being gradually but surely built up. After all, a paper agreement is a bruised reed to rely on if the attitude of each party is one of suspended hostility, or even of mutual suspicion. (Seldom has a more salient example been forthcoming of this than in the present engineering dispute.) Schedules of wages and so forth could have been formulated by *ad hoc* joint committees, but what would they have been worth without the continuous influence of the Councils, which is the sole vital and integrating force which prevents all these schedules being treated, sooner or later, as dishonoured "scraps of paper."

The Critics' Fundamental Error.

But the fundamental error of the critics of the Whitley Councils lies in the assumption that a permanent "settlement" can be arrived at between Capital and Labour, and after that each can go its own way. But this state of industrial affairs is long since past—anyhow, in such a highly organised industry as that of electricity supply. In modern industry, as in modern matrimony, workman's rights like woman's rights have come to stay. We have a new state of affairs, where the problem is to take the new conditions as we find them, and evolve a *modus vivendi*, or in other words, some satisfactory mode of *continuous relationship*. This is a psychological, not a legal problem, and it is the virtue of the Whitley system that it is constituted so as to achieve this—the only industrial machinery, in fact, which has ever been capable of doing anything at all in the way of maintaining a continuous relationship between both sides.

What the Councils Have Done.

How the Whitley councils have accomplished this is obvious. It is a natural result of their procedure. You cannot meet a man face to face every month or so and discuss with him at length intimate problems which affect his life and well-being (and your well-being too) without either becoming determined enemies and breaking off negotiations or else becoming something very like friends. Further, when the watchword is (as in the Whitley councils) "we meet as friends," then each party instinctively curbs any unfriendly proclivities, and it only requires time for the ideal tone to become the real tone. The old spectres vanish from the dispute, or are laughed away. You cannot visualise the opposite side (if you are an employer) in a lump, as Bolshevists or so on, or (if you are an employee) as grinders of the face of the poor. You cannot theatricalise the situation when you are sitting calmly and quietly facing each other time after time across the Ministry of Labour's tables. You have to let go the hereditary and clap-trap feuds between abstract capital and labour.

As Human Beings.

You have got to deal with each other as human beings as reasonable as your individual interests at the moment will allow you to be. And so you come, willy nilly, to more and more of a mutual understanding. Such, indeed, is the inevitable result of the Whitley system when comprehensively applied to an industry as it is in the electricity supply industry, a result none the less valuable since it is wholly psychological. And it is just this important aspect of Whitleyism that we would specially commend to the consideration of the critics when they talk as though the industry would go on just as well if the Whitley Councils were snuffed out.

Electrification of Swiss Railways.

In his report for 1921 on the economical and commercial conditions in Switzerland Mr. J. Picton Bagge, H.M. Commercial Secretary at Berne, states that the electrification of the Gotthard line is making satisfactory progress. Work on the line Lucerne—Zug—Zürich is proceeding, and is expected to be completed by the end of 1922. It is anticipated that electric traction will be started on the Sion—Lausanne section in the course of 1923. The electrification of the Berne—Neuchâtel line as well as of the Emmenthal group of lines has been postponed owing to the fall in the price of coal.

This latter, together with the high capital outlay involved by the present cost of labour and materials on the construction of the great dams and other necessary works, has made the extension of electrification schemes a matter of grave consideration. It is doubtful however, Mr. Bagge states, whether Switzerland, in view of the anxiety and loss suffered during the war through difficulties in the coal supply, can afford to renounce schemes which insure her against any possible recurrence of such troubles.

With regard to the electrification of private railways, the Rhetian Railway has already 200 km. of line run by electric power, and the electrification of the Reichenau—Ilanz—Disentis line is expected to be completed this summer.

Water Power.

The total water power available in Switzerland is estimated at 4 000 000 H.P. New principals and regulations for the exportation of electric power were established by the Federal Council in its sitting of June 3.

The Royal Society Conversazione.

To the electrician the most interesting novelty among the exhibits at the first ROYAL SOCIETY CONVERSAZIONE, on May 17, was the demonstration, by MR. W. M. MORDEY, of some very curious effects of alternating magnetism. Mr. Mordey had arranged 12 poles of finely-laminated electro-magnets, wound for monophase or diphase circuits, in a row, the laminations being parallel to the common longitudinal axis of the poles. On the poles he placed small and large trays, made of glass and cardboard, containing coarsely or finely-powered magnetic materials, pure or mixed with sand, etc. In ordinary experiments laminated alternating-current magnets are supposed to behave like direct-current magnets, and they do not appear to offer any special advantages for the magnetic ore concentration. Mr. Mordey's striking demonstration will alter that view, and the phenomena, which Mr. Mordey associates with hysteresis susceptibility, should be seen fully to be appreciated. When filings of iron, nickel or cobalt, were placed, say, on the left side of the tray, which covered several poles, the particles merely arranged themselves axially with the monophase currents. When the second phase was turned on, the mass became greatly disturbed and the particles were impelled in three directions, upward, longitudinally to the right and crossways. "Planes of force" formed on the left side, the particles standing up in parallel fins more than a centimetre in height; the material was drawn in on the left and expelled to the right, new fins finally forming on the right wall of the tray. The particles travelled rapidly, at the rate of several inches per second, and the upward movement was so lively that glass covers had to be put over the trays. When the tray was moved crossways, the planes of force swayed to and fro with the motion; when the field was weakened or the tray lifted higher, the planes would collapse while the movements continued. One thinks of eddy currents as the cause; but powdered aluminium gave no effects at all, and when a copper disc, capable of spinning about a vertical axis, was approached to one of the poles, the rotation in the half of the disc over the pole was to the left, *i.e.*, opposite to the migration of the iron filings.

Equatorial Grouping in Monophase Fields.

Magnetite and iron sands from New Zealand and powdered stalloy behaved similarly to iron filings, but the effects were less marked. Specular haematite seemed to vary. This iron-grey variety of haematite (iron oxide) is paramagnetic, though very feebly. In a one-phase field of two poles only, the haematite placed itself equatorially, like a diamagnetic material. But when the tray was put over three poles (of the row of electro-magnets), and the central pole was not excited, the particles arranged themselves in two intersecting rings about the poles, while the square outlines of the poles were indicated by tufts of the powdered material; and it was shown that the equatorial grouping was a special case of monophase fields with small pole gaps. When the magnetic materials (comprising earthy red haematite) were mixed with sand, the magnetic materials were driven out of the sand, in the same three directions, especially when the sand was stirred, the ore collecting on one side. A mixture of tungsten and tinstone was sifted and the tungsten concentrated in the same way. Similar movements, modified by buoyancy and surface tension, are further observed in water, and Mr. Mordey has also experimented on the treatment of ore slimes. As regards the theory, the number of laminations has at any rate no direct connection with the number of the vertical planes of force mentioned, and moderate frequencies (85 periods per second were used) seem desirable. At 150 and 350 periods haematite particles stand erect, oriented to the poles, but without motion, and Mr. Mordey assumes the hysteresis has ceased or is diminished at 150 periods.

Hughes' Historical Apparatus.

Historically we ought to have mentioned the original microphones of 1878 and Experimental Apparatus of DAVID E. HUGHES in the first instance. These were exhibited by the Science Museum at South Kensington and comprised the original model of his induction balance and of the apparatus for the transmission and reception of wave signals, which Hughes showed at the Royal Society Conversazione in 1879.

In the astronomical clock and uniform motion governor of Lord Kelvin, now in the entrance hall of the Royal Society building, the Graham dead-beat escapement wheel is reduced to a rotating arm so that the whole train of wheels need not be stopped by the pressure of a tooth moving with the pendulum. The original hand-winding mechanism (with its weight dropping 11 ft.) has been replaced by the CAMBRIDGE AND PAUL INSTRUMENT COMPANY by an electric automatic winding gear of the type adopted by Howard Grubb for equatorials.

Radio-telegraphic Records.

Mr. A. A. CAMPBELL SWINTON'S radio-telegraphic records obtained by various methods comprised string galvanometer records obtained with signals sent from the Poulsen arc station at Tralee, in 1910, and the most recent Creed perforated tape Roman type prints. The telephone transmission measuring apparatus exhibited by the WESTERN ELECTRIC COMPANY, gives direct readings of the transmission loss of telephone apparatus in miles of standard cable as well as visual readings. The high-frequency oscillator consists of a voice-oscillator (200 to 3 000 cycles) and an ultra-audio oscillator (up to 50 000 cycles in steps of 100 cycles) provided with inductance and condensers to filter out higher harmonics.

The precision bridge for platinum thermometry of the National Physical Laboratory was designed by Dr. F. E. SMITH. There are two potential and two current leads; one of these is shunted as in a Kelvin double bridge, one is in the galvanometer circuit, and two are in the variable bridge arms; the resistance of these two arms is about 100 times that of the thermometer, steps on the lowest dial corresponding to 0·001° C.

New X-Ray Apparatus

There were two new X-Ray Bulbs. The one, exhibited by Sir WILLIAM BRAGG and Prof. W. L. BRAGG, together with numerous models, mostly on a scale of 100 000 000 to 1 of crystal structures of inorganic and organic substances, is a wide glass cylinder closed at both ends by brass mountings for connection with air-pump and cold water pipes. Along the axis of the cylinder runs a brass tube enclosing the long leads of the tungsten filament, the rays from the target pass through an aluminium window outside and fall on the specimen, a crystalline powder pasted on paper. The other bulb, shown by the Radiological Branch, Woolwich Research Department, is made of iron and glass, and is self-shielding. The kathode tube fits into the stem of an iron cup; the anode, also iron, is separated from the cup by a sleeve of glass. The cup and anode are water-cooled. The rays fall through an aluminium window on the material which, as in the Bragg tube, is quite close to the window. The apparatus is designed for the testing of explosives, the dielectric constants of which are determined with the aid of another apparatus exhibited by the Explosives Branch of the same department. The specimen is placed in a condenser, and the pitch of the note given by two valves at radio frequency on the heterodyne principle is altered; by means of a variable condenser the original pitch given by a tuning-fork is restored.

New Microscope Lamps.

The many microscopes served chiefly for the display of physiological specimens. New microscope lamps were shown by the NATIONAL INSTITUTE for MEDICAL RESEARCH (quartz-mercury lamp); by Mr. J. J. FOX, a monochromatic illuminator without lenses with rapidly interchangeable parts (made by Messrs. BELLINGHAM & STANLEY); and by Messrs. OGILVY & Co., a new gasfilled lamp (mounted on a tripod base to which a small optical bench is attached), made of a very fine opal glass which obscures the metal filament and does not show any grain of the glass.

Cutting Tool Stresses

We briefly notice a few other exhibits. Prof. E. G. COKER demonstrated, on behalf of the Cutting Tool Research Committee of the Institution of Mechanical Engineers, the action of milling and cutting tools and the stresses set up in the material by means of his beautiful polarisation apparatus. Mr. CECIL C. MASON, of Cambridge, showed an autographic record indicating the loss of rotational velocity of a projectile during flight, obtained for the Ordnance Committee. The CAMBRIDGE AND PAUL INSTRUMENT COMPANY exhibited a new micro-indicator for high-speed engines, the invention of Mr. W. G. Collins, by means of which ten indicator diagrams are scratched on a celluloid disc within half a minute; the disc is placed under a microscope provided with a guticule. Enlarged photographs of these permanent records should prove very useful, especially for taking track tests and studying aeroplane flights. The simple original apparatus, which weighs about 1 lb., comprises an automatic electric switch driven by the engine. This is screwed into the top of the cylinder.

Modern Lamp Manufacturing at Dalston.

Although the general run of the methods employed is well known to readers of The Electrician, it is not realised fully how great a part engineering skill and inventive genius play in lamp manufacturing operations of the present day. That this is so was, however, obvious during the course of a recent inspection of Siemens Electric Lamp Works at Dalston.

The Siemens factory at Dalston is a modern six-floor building, which was originally erected in 1902. Compact but roomy, it is conveniently situated for delivery purposes and in an area in which labour is plentiful. As will appear from the following description, novel and intricate automatic machinery is employed for the various operations to a much greater extent than hitherto. This is maintained by the engineering staff of the firm, and in fact certain machines are of Siemens' exclusive design, among them those which are being used for spiralling and for making the pigtail loops for the filament supports.

Filament Manufacture.

Perhaps the most interesting of the processes employed in the manufacture of the lamps is that of the filament itself.

The starting material is ordinary commercial oxide of tungsten. This is first chemically purified and the purified oxide is then reduced to metal by heating in a current of hydrogen, the result being grey tungsten powder.

This powder is pressed under hydraulic pressure into a stick 7 in. long by $\frac{1}{4}$ in. square, which is baked in order to increase its strength for subsequent handling. The baked slug is then "sintered" by raising it to a blinding white heat by means of an electric current in an atmosphere of hydrogen. (This operation, for convenience, is carried out at Woolwich, and not at Dalston.) The slug at this juncture becomes a solid piece of tungsten metal, the particles having been welded together by the sintering process.

The sintered slug is now passed through the hammering or swaging machine, its diameter being reduced from $\frac{1}{4}$ in. square section down to a diameter of 32 mils. round. The length of the slug is gradually increased on each successive pass through the swaging dies from a length of 7 in. up to over 30 ft.

Drawing the Tungsten Wire.

The wire is next drawn through a succession of diamond dies on machines specially designed for the purpose. The wire is passed through a lubricating bath and heated before entering the dies, after which it is automatically wound on to small drums or bobbins. This process is repeated on a number of wire-drawing machines, each of which has a smaller die, so that the wire is eventually reduced to the diameter desired.

Photo-Micrographic Records.

Owing to the importance placed on the quality of tungsten produced, a plant for taking photo-micrographs of the tungsten, both in slug and wire form, has been installed. By this means the grain and fibrous texture of tungsten produced from various mixtures can be examined and the changes which take place after the tungsten has been under current in an electric lamp compared.

The Spiralising Processes.

The spiralising of the filament, which is the next process with which we may deal, is now done exclusively by machinery. For the heavier gauge wires a number of automatic machines of special design which can be regulated to wind any desired style of filament are being used.

The wire is wound on to a mandril in a similar manner to that employed in making an ordinary spiral spring, with the exception that in these machines the holder containing the drum of tungsten wire is carried on a traversing attachment to ensure even winding. The wire is passed through adjustable tension grips, and the traverse is automatically "tripped" at intervals, so that a number of short straight lengths of wire are left between the sections of spiralled filament. These facilitate mounting on the spider and occur where the filament passes through the supporting loops.

The process is different for the fine wires. In this case a mandril composed of soft brass wire is fed into the machine from a drum, and the filament is spiralised round this as it passes through the machine. Then the wire mandril with the spiralised filament round it, is rewound on to a separate drum. Owing to the small diameters worked on these machines it is practically impossible to remove the spirals from the mandril in the ordinary manner without damaging them, so the former is dissolved in a chemical solution, leaving the spiralised wire intact ready for mounting on the spider.

Foot and Spider Making.

The combined foot and spider is the interior glass structure which provides a sealed entry for the conducting wires, and to which the filament supports are attached. The design varies in accordance with the type of lamp manufactured, but generally it is made up of three component parts—the flanged leading-in tube, the leading-in wires, and the glass stem. After manufacture the three component parts are assembled on the foot-making machines. In this operation the leading-in wires and the stem are first fixed in their correct positions in the flanged tube. The glass components are then heated to a suitable temperature by means of gas flames, and the "pinch" is made which hermetically seals the lower end of the flanged tube, and at the same time welds the stem and the leading-in wires into the "seal."

Details of the Spider.

The spider is built up on the glass stem and provides a method of supporting the filament. The design varies for different types of lamps, but the process is similar for each and consists of two operations. A suitable number of roses or buttons are first formed on the stem by heating to a suitable temperature and pressing. The radial supports are then fixed into these, the number of supports being determined by the type of lamp.

In the past these two operations were carried out separately and by hand, but some special machines in which the two processes are combined have been installed. The assembled foot and stem is placed in a machine and the button or rose is first formed by heating the end of the stem to a suitable temperature and pressing. The machine next brings the stem into the correct position for fixing the spider arms. The wire used for these is fed into the machine from bobbins, and gas jets are concentrated on to the glass button in order to raise it to a suitable temperature to receive and hold the supporting wires. The machine automatically adjusts the lengths of the supports and forms the pigtail loops.

Filament Mounting.

The first operation in filament mounting is placing it on the pigtail hooks. This process is accomplished completely by hand. The filaments for the varying types of lamps are supplied specially spiralised to suit the design of lamp required, and the ends are securely fastened to the leading-in wires.

In the case of high wattage gasfilled lamps where the leading-in wires are required to carry a heavy current, metal tape electrodes are used instead of the round wire conductors employed in the lower wattage types. The ends of the filaments—which are necessarily of fairly heavy gauge—are secured to these metal tapes by a process of spot welding

All spirals are carefully inspected before being mounted on the "foot." This is especially necessary in the case of the very fine filaments used for the 30 and 40 W gasfilled types of lamps, where the filament diameter is approximately 1/1000th of an inch. These small spirals are examined by placing them in an optical apparatus, which projects the highly magnified image of the spiral on to a screen. Subsequently the lamps are flashed and sealed in.

"Pipless" Lamps.

In this connection it may be recalled that the modern trend in electric lamp making is in the direction of so-called pipless lamps. Certain types of gasfilled lamps are now being marketed in which the pip is concealed within the cap of the lamp, thus leaving the base of the bulb perfectly rounded. This is arranged for when the "foot" is made. A small stem tube is passed through the flanged leading-in tube, and welded on to the "foot" just above the "pinch." The filament is then mounted and the completed foot is sealed into the neck of the bulb in the ordinary way. The bulb is afterwards exhausted through the stem tube and the pip is formed at the cap end of the bulb. It is found that this method does not add materially to the cost of manufacture, while the elimination of the "pip" end from the finished lamps, considerably reduces breakages in transit.

The Institution of Electrical Engineers.

There was a very crowded attendance at the INSTITUTION OF ELECTRICAL ENGINEERS on Thursday last, to hear Sir Ernest Rutherford give the Kelvin Lecture on "Electricity and Matter."

Mr. J. S. Highfield (President), before calling on Sir Ernest Rutherford, announced the result of the ballot for the election of President and Council as follows:—*President*, Mr. F. Gill; *Vice-Presidents*, Dr. W. H. Eccles and Mr. A. A. Campbell Swinton; *Hon. Treasurer*, Sir James Devonshire; *Members of Council*, Mr. J. W. Beauchamp, Mr. R. A. Chattock and Major Kenelm Edgcumbe; *Associate Members of Council*, Mr. F. W. Crawter, Mr. H. F. Harmer and Mr. W. R. Rawlings; *Associate*, Mr. D. N. Dunlop.

The Faraday Medal.

Continuing, the PRESIDENT said he had an announcement to make. At its meeting on February 16, 1922, the Council decided to institute a bronze medal, to be designated "The Faraday Medal of the Institution of Electrical Engineers," to commemorate the fiftieth anniversary of the first ordinary meeting of the Society of Telegraph Engineers, now the Institution of Electrical Engineers. The medal might be awarded by the Council not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous services rendered to the advancement of electrical science, without restriction as regards nationality, country of residence or membership of the Institution. With the medal would be presented a parchment certificate of award. A bronze medal was chosen rather than a gold medal, first because a gold medal was a rather difficult piece of property to take care of, and a bronze medal could be an equally beautiful work of art, and it was also desired that there should be no suggestion of any intrinsic value in the medal itself, but rather that it should owe its value first to the fact that it was to commemorate an important event in the history of the Institution; secondly, that it was offered for world-wide services without any restrictions; and, lastly, that it was hoped, as time proceeded, its importance would be advanced by the illustrious names of its holders. A design prepared by Mr. Metcalfe had been adopted for the medal. It was intended to announce the institution of the Faraday Medal during the Commemoration Meetings, but circumstances arose which prevented this being done, and he felt considerable personal pleasure in the delay. He was still more pleased to be able to announce that the Council had made the first award to Oliver Heaviside.

He need say no more about the life work of Oliver Heaviside than was contained in the resolution passed at the Commemoration Meetings, which he read. Heaviside was one of our famous men who in his work displayed the wide and fearless view of the real pioneer. He was sure that all present hoped that in the evening of his life he might feel that those who followed him revered his name.

The Heaviside Layer.

SIR OLIVER LODGE, who was greeted with prolonged applause, said it was an unexpected privilege to be called upon to support the action of the Council. He congratulated the Institution on the use it had made of its first Faraday Medal. A man like Oliver Heaviside, who wrote very abstrusely, and who a good many years ago retired into private life and into the heart of the country, might very well have been forgotten and overlooked. They had sent him an eloquent message, and they had made him the recipient of the first Faraday Medal. Oliver Heaviside might pretend that he did not care much about medals; he was given to express himself in peculiar ways about things of that sort, but he could not but appreciate the feeling which lay behind the award, and the words of the message which had been sent him must, if he were human, give him joy. He understood that the President had been down to see Mr. Heaviside in the country, and that it was his intention to go again and take the medal, which they could not expect Mr. Heaviside to come to London to receive, so that whether Mr. Heaviside liked the medal or not, he would at any rate like the visit of the President.

SIR ERNEST RUTHERFORD then delivered the Kelvin Lecture on "Electricity and Matter," which we shall deal with in a subsequent issue.

Correspondence.

IMPERIAL WATER POWER PROGRESS.

To the Editor of THE ELECTRICIAN.

SIR,—We note in the April 21st issue of THE ELECTRICIAN an article under the heading of "Imperial Water Power Progress," referring to the operations of the Hydro-Electric Power Commission of Ontario, in which you have made certain reference to recently published and widely distributed criticisms of the Commission's activities, by Mr. W. S. Murray, a New York engineer, employed by the National Electric Light Association, an organisation under the absolute control of the private power interests of the United States.

In your comments regarding the Murray Report, we note that you have taken for granted that Mr. Murray's statements are all true and that his conclusions are correct. Located, as you are, a long distance from the Province of Ontario, would it not be well, before condemning the largest and most successful co-operative municipal ownership undertaking in the world, to obtain the actual facts of the case, so that your readers may not be misled in their judgment of this great scheme, in which you, as publishers of a technical journal widely read throughout the British Colonies, should be vitally interested, as we believe it is your aim to publish facts and not fiction in your journal.

Regarding the Murray Report, I might say that this Report was prepared to the specifications of the National Electric Light Association, by Mr. Murray, criticising the Commission's activities, in an attempt to stem the tide of public opinion, which is rapidly crystallising in the United States and other parts of this continent in favour of Municipal Ownership of Public Utilities, similar to the plan that has been in such successful operation in the Province of Ontario for the past eleven years. Mr. Murray's Report is full of mis-statements and comparisons of figures not comparable.

We are, at the present time, preparing a reply to the Murray Report, a copy of which we will forward you for your information, in order that you may be in a position to correctly inform your readers regarding publication.—We are, etc.,

F. A. GABY,
Chief Engineer.
Hydro-Electric Power Commission of Ontario.

Toronto,
May 8th.

DOES THE INSTITUTION NEED A WIDER OUTLOOK?

To the Editor of THE ELECTRICIAN.

SIR,—On several occasions after some years residence abroad I have, on coming home, been struck by the insular parish pump point of view that characterises meetings of the Institution of Electrical Engineers. Naturally having its origin in Great Britain the happenings here must loom large at the meetings and in the proceedings, but the Institution has now widened its activities to all parts of the British Commonwealth and moreover is concerned with a branch of engineering that has a world-wide appeal. I think therefore, that matters that happen outside the British Isles should receive more attention than they do and also that speakers in the discussions might endeavour to see things in a broader way.

Readers may have noticed that the Institution of Civil Engineers is as much interested in engineering abroad as in what happens at home and the proceedings of the I.C.E. contain many papers descriptive of engineering work in all parts of the world. Partly as a result, the membership is very wide-spread.

Engineers as a class travel a great deal, and large manufacturing concerns are as much interested in orders from overseas as they are in local orders so the Institution membership must contain many members who think as I do.

I suggest that a suitable leaven of engineers (now resident in this country), who have lived in some particular country overseas long enough to know intimately actual conditions, should be introduced into the Council in order to ensure that the proceedings of the Institution shall in future have that wider outlook which several observers as well as myself, feel that it needs.—I am, etc.,

E. KILBURN SCOTT.

London, N.
May 16, 1922.

Centrifugal Clutches and Small Motors.

A simple and inexpensive device to enable small power motors from ¼ H.P. to 1 H.P. to start up freely has long been needed. Engineers have made many attempts to overcome this starting torque difficulty by improving the design of the motor or by special switchgear, but neither of these improvements has given real satisfaction. It is, therefore, interesting to note that THOMAS BROADBENT AND SONS, of Huddersfield, have recently been investigating this matter

FIG. 1.—THE PARTS OF THE CLUTCH.

and after considerable experiments have designed a small and compact centrifugal clutch, which appears to have solved this complicated problem. This small clutch embodies all the features of the firm's well-known larger power clutches.

The purpose of a centrifugal clutch is to enable the motor to accelerate up to 75 per cent. of full speed *without load*, the load being then gradually and automatically applied until at full speed the

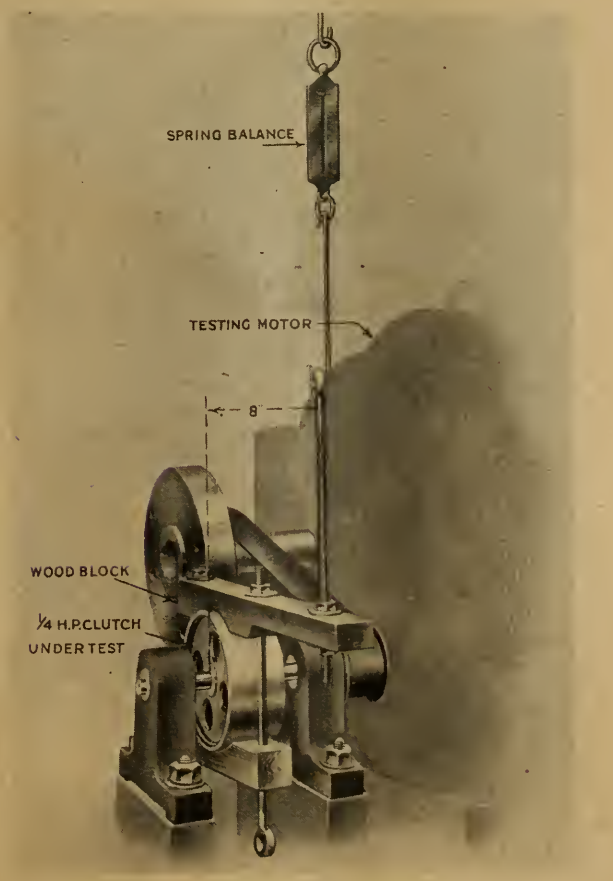

FIG. 2.—THE CLUTCH UNDER TEST.

drive becomes positive. The clutch forms part of the driving pulley or coupling as the case may be and can be adapted to almost any type of drive.

Details of the Clutch.

Briefly described, this small power clutch consists of a centre-piece or spider which is keyed to the motor spindle and carries with it two loose friction shoes with "Ferodo" facings, carried in suitable pockets and clear of the driving pulley rim. These shoes are spring controlled, the tension of the spring being adjusted to retard any movement of the shoe until the motor has attained 75 per cent. full speed.

Immediately this speed is reached the shoes are automatically thrown radially outwards by centrifugal force and engage with the interior face of the belt pulley, thus gradually accelerating the driven machine to full speed. The weights of the shoes are so regulated that when the motor is running at full speed the friction developed exceeds the power of the motor, and, by this means the motor is enabled to start up and accelerate absolutely without load. If desired, the clutch can be arranged to slip at any desired overload, thus acting as a safety overload device.

Test Results.

Broadbents have just supplied a number of these clutches to the General Post Office for use with ¼ H.P. stamping machine motors. The sizes ranged from 4 in. diameter to 5¾ in. diameter at speeds varying from 1 400 revs. per min. to 1 700 revs. per min., and arranged for both flat and round belt drives. Before despatch these clutches were put through the usual tests and some very interesting data was obtained which showed that in every case the motor attained a speed of well over 1 000 revs. per min. before any load came on. The clutch then began gradually to pick up until at full speed the torque transmitted well exceeded the power of the motor.

Fig. 1 illustrates all the interior parts of the clutch, consisting of a hollow driving pulley, a central disc or spider fastened to the motor spindle containing two loose friction shoes and an end cover plate and spring for fastening the plate. It will be seen that the clutch is of such simple design that it cannot possibly get out of order; there are no metallic wearing parts and the action is entirely automatic. The clutch cannot fail to positively pick up the load after the motor has attained pre-determined speed.

Fig. 2 shows the arrangements that were made to carry out the tests. This type of clutch will probably become standard practice for use with small power motors, and engineers will therefore be well advised to give it their serious consideration.

A New Network Box.

CALLENDER'S CABLE AND CONSTRUCTION COMPANY have lately put on the market a new design of network box, the two chief improvements on existing types being (*a*) the mounting of the fittings on metallic frames or grids; (*b*) the provision of renewable and adjustable spring contacts for fuses or links. In addition the new boxes embody an improved design of definite grip fuse or link extractor.

The insulators on which the fittings are mounted are carried on a grid consisting of steel rods which are supported at each side by metallic frames. This grid, with its fittings, drops inside the outer containing cast iron box and rests on feet provided on the frame. The insulators are moulded with grooves at each side so that they are readily slipped into position along the steel rods. This form of construction gives the necessary rigidity and mechanical strength, provides a clear space on the underside of the grid for the cables to be jointed in the box, permits ready assembling and jointing, and also enables the interior gear of the box to be packed for transit separately from the outer containing cast iron box, thus reducing breakages. With the new arrangements of gear no joints other than sweated joints are below the compound level, which is a great advantage and one which will be appreciated by those who have charge of the maintenance of network boxes.

The Callender-Watson Spring Clip.

A special type of spring clip—the Callender-Watson—has been evolved after months of experimenting, which, it is claimed, has none of the disadvantages of the usual type spring clips, which are invariably either too flimsy and result in undue heating, or are so constructed that it is impossible to renew them without considerable trouble and expense. These spring clips form part of a loose contact head which is connected to the cable or busbar stalks by a grip contact which introduces a minimum electrical resistance. The stalk is supported in the insulator by means of an internal nut, so that when the contact head is removed for any purpose there is no possibility of the stalk dropping down and making contact with the bottom of the box.

Manipulation of Fuses.

The question of the manipulation of the fuses or links has received considerable attention. It was considered undesirable to provide each fuse with its own handle, as this increases the cost. On the other hand, the form of loose porcelain handle supplied with the old Callender-Ward pattern boxes had the disadvantage that when used by inexperienced operators the fuse or link was apt to slip out of the handle. In the new fuse extractor supplied with the C.S.W. type of box, however, a definite grip on the fuse holders or dollheads is obtained. This extractor is made in Kalanite, and consists of a two-part handle, one half being made to slide over the other. In cases where customers prefer enclosed fuses, these can be supplied.

Langmuir Condensation Pump.

The Langmuir condensation pump is now being manufactured in Rugby by the British Thomson-Houston Co., who are the owners of the English patent rights.

The Langmuir pump has been designed to produce very high vacua—much higher than can be obtained by other means—and is therefore of value in connection with the manufacture of electric lamps and for many forms of research work. By its aid pressures lower than 10·5 bars have been produced and measured and a speed of 3 000 to 4 000 c.c. per second is obtained under normal working conditions.

The action of this pump is briefly as follows: The mercury in the base of the pump is heated by a gas burner and the mercury vapour which is given off impinges on the baffle-plate at the top of the heating chamber. This baffle-plate deflects the mercury vapour downwards and outwards into the water-cooled condensation chamber, where it mixes with the gas to be removed. This gas is thus carried downwards by the mercury vapour until the vapour condenses, when the condensed mercury flows down the walls of the chamber and returns to the base of the heating chamber while the gas is carried to the atmosphere by means of an auxiliary pump.

Fig. 1.—Langmuir Condensation Pump.

Amount of Mercury Required.

The proper amount of mercury required for each pump is 626 gms., and should consist of mercury which has been thoroughly cleaned and preferably distilled.

The gas burner is fixed in position beneath the heating chamber, the connection to the gas supply being made by means of ordinary rubber tubing. The amount of air supplied to the bunsen burner should be regulated to obtain a non-luminous flame, and the mercury kept boiling steadily, but not too vigorously, so that condensation may be as complete as possible in the water-cooled chamber. It should always be ascertained that the water is flowing through the condenser at the proper rate before heating is started.

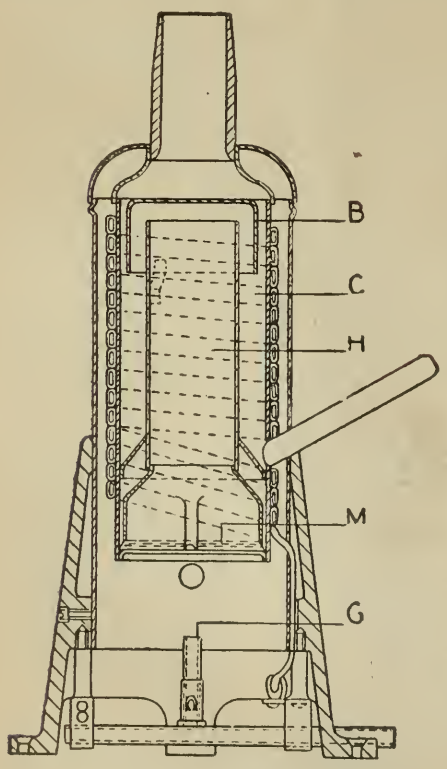

Fig. 2.—Diagram showing Construction of Langmuir Condensation Pump.

Both water connections extend from the bottom of the pump, and can be used for either inlet or outlet. Ordinary rubber tubing is suitable for connecting to the water supply, the tubing being firmly bound to the pump connections and source of supply. The rate of flow of the water should be about 1 000 c.c. per minute.

Methods of Connecting.

The method of connecting the condensation pump to the vessel to be exhausted depends on individual requirements. A ground-glass connection to fit the top vacuum port or a metal connection ground to fit the port may be used—the joint being carefully greased, but care must be taken to prevent any grease from getting to the pump. Another method is to fit, a copper cup over the top vacuum port and by means of sealing wax to make a vacuum-tight seal. A suitably shaped glass connection may thus be fitted over the vacuum port and sealing wax melted in the metal cup until it melts and flows round the end of the glass connection: when the wax cools an efficient joint is made, which can easily be broken if required by reheating the wax in the cup.

In some cases the presence of mercury vapour in the vessel being exhausted may be detrimental, and this may be avoided by putting a trap (cooled by solid carbon di-oxide or liquid air) between the pump and the vessel.

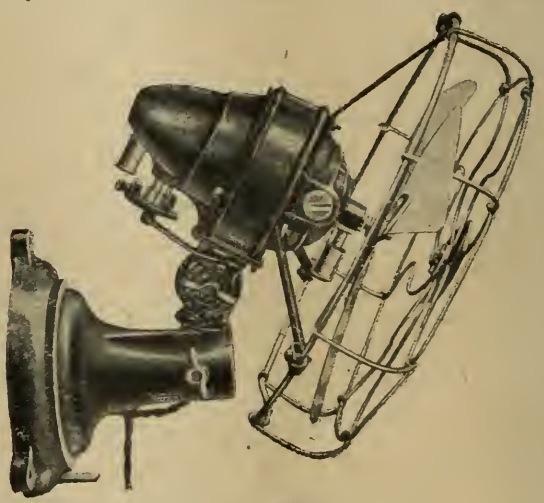
The auxiliary pump is connected to the small vacuum port in the side of the condensation pump by means of stout-walled rubber tubing, and should be capable of producing a vacuum of 0·1 mm. of mercury. If an oil-sealed pump is used as auxiliary, a pinch cock should be fixed between the two pumps to prevent oil entering the condensation pump when shutting down the system.

Method of Cleaning.

The presence of a very little oil or dirt in the inner chamber will make the pump ineffective. To clean, the mercury is first removed by turning the pump upside down, having the large vacuum port closed with the hand, and then returning the pump to an upright position and pouring the mercury out of the smaller port at the side of the pump. This is repeated until all mercury has been removed. Petrol is then poured through the large vacuum port, and the pump shaken vigorously thoroughly to wash the interior. In the same manner the petrol is removed and the washing repeated with benzol. The vapour of petrol or benzol left in the pump is exhausted by means of the auxiliary pump before replacing the correct weight of clean mercury.

G.E.C. "Freezor" Fans.

The General Electric Company announce that they are launching this season a great "Freezor" fan campaign. Full particulars of the campaign, which is designed to assist the trade, will, they state, be announced in due course. Meanwhile we have received an advance copy of a booklet V.2754 which gives full descriptions of the numerous types of "Freezor" fan, together with revised prices which, we notice, represent very substantial reductions. This is just the weather for fans.



The Latest "Freezor" Fan.

New Range of Oscillating Fans.

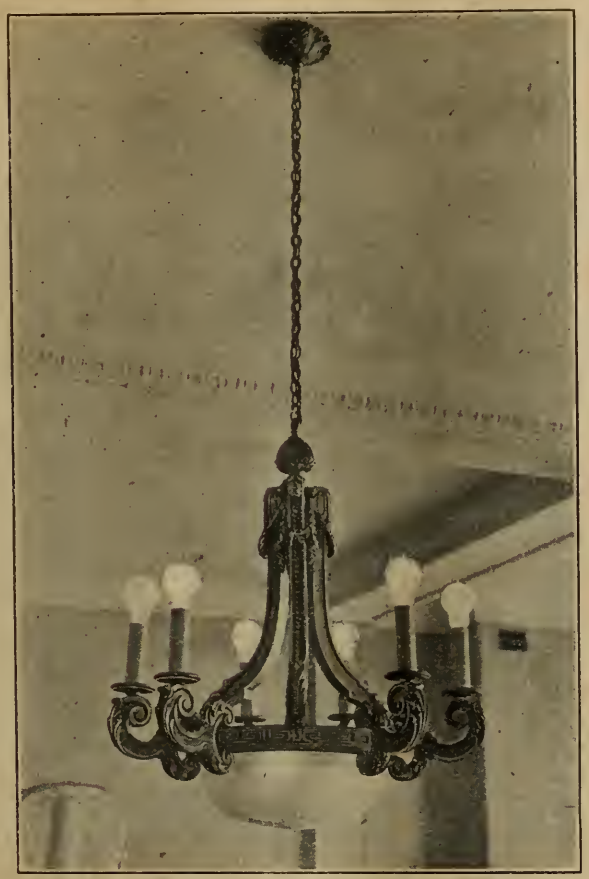
This booklet contains amongst other things details of a complete new range of oscillating fans. These fans represent an entirely new departure in oscillating fan construction, and are claimed to be the only fans of their kind manufactured in England. They are fitted with a very simple and efficient oscillating mechanism. The arc of travel can be adjusted between the limits of 110° and zero and a slipping clutch is provided which allows the blades to continue to revolve even when the oscillating mechanism is prevented from operating by some external obstruction. These fans, one of which is illustrated, are made for d.c. and a.c. circuits in two sizes with blades 12 in. and 16 in. in diameter, and can be easily converted from table pattern to bracket pattern by loosening a thumb screw. The blades are stout sheet brass punchings and are carefully dished to give a definite curvature which has been found by experiment to give a maximum air delivery with a minimum of air friction losses.

The vanes are rivetted to a stout spider which guarantees a rigid structure capable of standing up to air resistance without warping or creaking and the complete rotating portion—armature and blades—is carefully balanced and tested at the works before being finally passed.

H.M. Consul at Colon, Republic of Panama (Mr. C. Graham), reports that a general importer and manufacturers' representative is desirous of forming connections with United Kingdom firms for electric motors and electrical supplies, and steam, water, wind and air motors. Further particulars may be obtained from the Department of Overseas Trade.

The "Ediswan" Fullolite Lamp.

The Royal "Ediswan" Fullolite lamp is already well known to our readers for its many advantages in the elimination of glare and its perfect diffusion of light. A happy adaptation of the lamps is shown in the illustration. The fitting shown is installed at the Oxford Street showrooms of the Rapson Tyre and Jack Co., Ltd.



"Ediswan" Fullolite Lamps.

The fittings, which have been supplied by Maple and Co., are of a massive type and are finished in gilt to harmonise with the general scheme of the showroom decoration, which is in gold and black. The candle flames are 40 W Fullolite lamps, and a practically shadowless distribution of light is given over the entire showroom.

We believe that this is the first instance in which these lamps have been adopted for this combined decorative and illuminating purpose, and the effect gained has certainly justified the experiment.

Advantage of Interlinking.

A good illustration of the advantage of the interconnection of electricity supply systems was recently given at Ontario, where, owing to accidents at two generating stations, the Hydro-Electric Power Commission was suddenly deprived of about 160 000 h.p. Within 15 minutes of the occurrence the Canadian Niagara Falls Power Co. and the Toronto Power Co. were feeding the system of the Commission, and part of the deficiency is also being supplied by the American plant of the Niagara Falls Power Co., so that the whole of the municipal power and lighting service in Ontario has been maintained without interruption.

According to the "Electrical World," the accident occurred at the Niagara Falls station of the Ontario Power Co. at about 3 a.m. on April 30, and is said to have been due to a short circuit on one of the Commission's transmission lines. Two 20 000 h.p. generator sets were destroyed, and as part of one of the generators was hurled through the roof the covering of the new wing fell and smashed the casings of two other turbines. Water then flooded the whole bay and rushed into the main power house, four 16 000 h.p. units being flooded. A few days prior to the accident damage was caused to a 55 000 h.p. generator set at the Chippawa-Queenston station, so that within a week the Commission lost the use of units aggregating 159 000 h.p. Some of the plant has been repaired, and by means of interlinking with neighbouring systems a full service has been maintained and no inconvenience has been caused to consumers.

The prospect of a settlement of the engineering dispute has improved during the week, as the 47 "other" unions involved have now agreed to take a ballot of their members on the proposals submitted by the employers on Saturday last. No definite recommendations will be made, but members will be asked to give the proposals serious consideration. The ballot papers will be returnable by June 2.

New Type of Lightning Arrester.

The Westinghouse Electric and Manufacturing Company has developed a new type of d.c. electrolytic lightning arrester, known as "Type AR," for car or station use on railway, power and lighting circuits.

The new type is for voltages up to 3 800, and contains one to twelve cells. Each cell consists of two aluminium plates immersed in a suitable inorganic electrolyte and supported from a porcelain cover clamped by a zinc ring to a glass jar with a gasket placed between the porcelain cover and the glass jar. Hollow concentric cylinders made from sheet aluminum form the plates, the outer cylinder or plate being punched and upset at frequent intervals in order to allow free circulation of the electrolyte within the cell. Balancing resistors are used with arresters of more than one cell. These resistors cause each cell to take its proper portion of the line voltage and thereby tend to keep the aluminum hydroxide films equally formed.

Position of the Arresters.

The arresters are "floated" between line and ground so that a leakage current of only a few millamperes passes continually. This leakage current serves to keep the film upon the aluminum plate or plates in proper order.

The product is capable of passing a surge current of approximately 1,000 A at double normal voltage when the arrester is functioning, and one arrester should be used for each 500 kW of feeder bus, rotary converter or motor generator capacity to which the arrester is connected. Any voltage in excess of normal line voltage is discharged promptly through the arrester.

Function of the Arrester.

The functioning of the "AR" type of arrester is similar to the functioning of a steam safety valve or a hydraulic release valve. When the impressed pressure, or voltage, exceeds the normal, the valve opens and the excess pressure, or voltage, is relieved; then the valve closes and is again ready for operation. A fuse is placed in series with the arrester cells to prevent destruction of the arrester in the event of a short or heavy discharge for an appreciable length of time occurring. Evaporation of the electrolyte in the cells is prevented by a layer of oil on the surface of the electrolyte.

The arresters are mounted and securely held in asbestos board and wool-fibre lined cypress boxes. The boxes with a flat top are intended for mounting beneath the car and with a slanting top for station, car interior, car roof or outdoor mounting on any vertical flat surface. Although all arresters are inherently outdoor arresters, they can be used satisfactorily indoors.

Electric Bread-baking Ovens.

Interesting particulars of an experiment made by Fisher Bros., of Cleveland (U.S.A.), in the baking of bread in gas and electric ovens are given in the "Electrical World." Two 1 000 loaf conveyor type ovens were used for a year. Formerly natural gas of approximately 1 000 B.Th.U. per cubic foot was used, costing 30 cents per cub. ft. or $66 a day. The electricity bill, at 2·38 cents per unit, came to $36, but, in addition to a greatly improved quality of bread, an unexpected saving was effected. It was found that the amount of flour required to turn out 125 000 1½ lb. loaves of bread a week was much less than had been the case with gas ovens, and ten additional 1½ lb. loaves were produced from each barrel of flour. As the firm use 57 barrels of flour a day, the additional loaves meant an increased income of $62·70 per day, or more than sufficient to pay for the increased cost of the electricity. Apart from the above advantages, with an electric oven so constructed as to retain the steam driven out of the loaves, it is unnecessary to inject live steam into the oven, thus avoiding the use of steam boilers, a matter of considerable importance in small bakeries.

Liverpool Sub-centre of the I.E.E.

The third annual report of the Liverpool Sub-Centre of the North-Western Centre of the I.E.E. states that seven general meetings have been held, with an average attendance of 99, when papers on various subjects have been read and discussed. The annual meeting was held on May 8, when Mr. B. Welbourn was elected chairman and Messrs. E. M. Hollingsworth and H. H. Harrison, vice-chairmen, for the ensuing year. Mr. O. C. Waygood was elected hon. secretary. The meeting was followed by a smoking concert.

The membership (including members, associate members, graduates students, associates) increased from 367 to 447. Members transferred to other districts numbered 38. The area of the Sub-Centre has been extended to include the whole of the County of Flint, Denbigh, Merioneth, Montgomery and Carnarvon, and also the Isle of Anglesey.

The Committee of the Students' Section record a very successful Session. Nine general meetings (average attendance 45) and one open meeting (150 present) were held.

It has been agreed between the Electrical Contractors' Association of Scotland and the Electrical Trades Union, in view of the reductions in wages which have taken place since the beginning of the year, that the present rate of pay should be stabilised until December 31 next, when it will be open to either party to review the situation.

F

Junior Institution of Engineers.

A dinner to celebrate the 38th anniversary of the foundation of the JUNIOR INSTITUTION OF ENGINEERS took place on the 18th inst. at the Café Monico, London, Mr. C. H. WORDINGHAM, C.B.E., being in the chair.

The fact that this Institution is regarded as a serious and important factor in upholding the traditions of the engineering profession was demonstrated not only by the professional eminence of the President, but by the attendance of such distinguished engineers as Dr. H. S. Hele-Shaw (President of the Institution of Mechanical Engineers), Dr. W. H. Eccles, Prof. E. G. Coker, Mr. W. B. Worthington (President of the Institution of Civil Engineers) and Mr. T. J. Gueritte (President of the Society of Engineers), while the number of grey heads at the function was sufficient to disabuse one's mind of any preconceived idea that "juniority" would be a prevailing feature.

Dr. HELE-SHAW, proposing the toast of "The Institution," commended the universal feeling of brotherhood which existed amongst the members. There were members present from places as far distant as India, China, and the West Coast of Africa. Many men who had been members had reached the highest positions. As an example of the serious work done by the members he referred to a Paper on "Friction," by Mr. C. H. Plant (with a prefatory note by Mr. E. C. West, Chairman of the Institution), in the May number of the Institutions "Journal" in which the subject was treated in an original way and the subject of electrons was gone into with great gusto.

Mr. E. C. WEST (Chairman of the Institution), in responding to the toast, said the sentiment which actuated the founders of the Institution 37 years ago that the whole of the proceedings should be based on friendship and good fellowship still held the Institution together. They had now nine local sections, amongst the recent additions being one in Assam and one in Australia, and the total number of members was just over 2,000. He mentioned that the Gustave Canet gold medal which was awarded annually to a gentleman of eminence invited to read a learned Paper before the Institution was to be presented shortly to Sir Eric Geddes, who would read a Paper on "The Railway Act, 1921."

Need for a Broad Initial Training.

Mr. C. H. WORDINGHAM, in reply to the toast of "Electrical Engineering" proposed by Dr. W. H. Eccles, said electrical engineering hardly had any separate existence apart from the older branches of engineering. Electrical engineering progress depended primarily on the men engaged in it, and their success depended primarily on character and secondly on training. Training, in the first stages, should be the broadest possible, so that, whatever branch a man finally elected to take up, there would be the solid groundwork of engineering principles to fall back upon. At a meeting of the Electrical Research Association recently, Dr. Eccles had said if there were to be much progress in a particular branch of research it was important to keep an eye on other branches of science and to see whether it might not be possible to apply discoveries in different directions to the particular branch in which one was interested. That speech made a great impression upon him, and it was one they should think over. The great difficulty was that there was such a vast mass of new material constantly welling up, that an engineer should know, that it was hopeless for him to try to deal with it. Attempts had been made to provide condensed selections by means of abstracts, but there were so many different institutions compiling abstracts, so many publications, more or less of a proprietary nature, and such a terrible profusion of periodical literature that it was impossible to read even the best of the matter thoroughly. Again there was much published that need not be—it was purely ephemeral. The great reason for this state of affairs was jealousy and envy. Each institution published its own Proceedings—they did not work together. Another difficulty was the multiplicity of things in which the proceedings were published. There ought to be some tremendous effort made to get a permanent record in which one could find what he wanted to know of progress and discovery during the year. Such a record might be issued weekly and might be the repository of all the Papers of the various Institutions that really mattered.

A European Automatic Sub-Station.

According to "The Times" Engineering Supplement, there is in Europe only one example of a sub-station with a completely developed automatic mechanism. This is used on the tramway between Basel and Lorrach. The equipment consists of a single 250 kW rotary convertor which transforms three-phase current at 6 300 V to direct current at 600 V. The necessary operations for starting and stopping are effected by a combination of relays, contact appliances and electrical remote control devices on the different switches. The electrical mechanisms that control the switches are positively connected with each other, and are divided into a connecting system and a disconnecting system, each of these systems being again divided into several groups. The connections are such that on starting or stopping work the switches always come into connection in the sequence required.

American Trade with Latin-America.

Increasing efforts are being made in the United States to develop trade with Latin-America and Spain, but more particularly the export of ELECTRICAL PLANT AND APPARATUS. As a result the electrical goods sent to these countries in 1921 was not less than in the previous year, notwithstanding the universal trade depression. Compared with 1914, the electrical exports show an increase of 240 per cent., the actual values being $10 194 964 in 1914, $34 456 554 in 1920, and $34 719 906 in 1921. The important items of export were batteries, insulated wire and cable, wiring accessories, incandescent lamps, switches and telephone material, though there appears to be an increasing demand at present for domestic apparatus and meters also.

Bright Prospects.

According to our contemporary, the "Electrical World," the outlook for all electric light and power apparatus in SOUTH AMERICA is bright; stocks are said to be low, political conditions are satisfactory, and an upward trade tendency is already noticeable. With the revival of industry in the United States and Europe there should be an increased demand for South American raw materials, and this should ultimately result in improved exchanges and a greater demand for manufactured goods.

In Spain, the openings are said to be limited, and are mainly for bare copper trolley and transmission lines and wire bars, dry batteries and pocket lamps. The situation in Spain, where a fair amount of hydro-electric development is taking place, is not so promising as in South America, as efforts are being made to establish local factories and there is also increasing competition from Germany.

The Brazilian, Mexican and Cuban markets are said to be likely to improve during the coming year, and regular types of American manufacture are recognised everwhere except in Argentina, Uruguay and Chile, where European types of material are employed and competition has to be faced. The trolley line material in use is also different from the American standard, and European lamps and meters have likewise a wide vogue and enjoy a good reputation. Lamps are being made in Brazil and Argentina, but the output is small. As might be expected, arc lamps are being discarded in favour of gas filled lamps for street lighting. There is an increasing demand for domestic apparatus (except labour-saving appliances), fans, ornamental fittings, etc., though Argentina, Brazil and Spain are endeavouring to meet local requirements by establishing factories for manufacturing cooking and heating apparatus.

Small Generating Sets in Argentina.

There appears to be an increasing demand for small independent plants for public buildings in the country towns in ARGENTINA, and also for farming purposes, especially in the northern part of the republic. The most popular lighting unit appears to be an oil or paraffin set, capable of supplying electricity to 40 to 70 16 c.p. lamps, or a 4 kW set for cinemas. Some German firms have already entered the field, and the Siemens-Schuckertwerke have recently introduced a new set. It must be remembered that small lighting installations must be economical in first cost as well as in operation.

In BRAZIL there is also a good prospect of a better demand for electrical supplies, but the import duties have been modified and increased. Duties are now mainly levied according to the weight and not on the *ad valorem* basis.

In regard to Latin-America generally, it must be remembered that the position of the United States, owing to its position and the financial assistance it has given, is much stronger than in pre-war days. During the past year the loans advanced by United States banks to South American countries amounted to $210 000 000, and it is hoped that, as the greater part of this sum will be spent on railways, harbour and other public works, many orders will be obtained for machinery, locomotives and rolling stock, telegraph and telephone materials, etc. In addition, efforts are being made to attract South American students to technical colleges and institutions in the States, because it is felt that when they return they will be familiar with American machinery and practice, and they will be favourably disposed towards American manufactures.

Possible Trade Openings.

An old-established firm of wholesale merchants at BUDA-PEST desire to obtain the representation of United Kingdom manufacturers of machine tools, electric motors, etc. Particulars from the Department of Overseas Trade. (Reference No. 575).

According to the "Industrial Daily News," important proposals for the ELECTRIFICATION OF THE DUCHY OF LUXEMBOURG have been submitted to the Government of the Duchy by a group of Belgian financiers. A central power station near the town of Luxembourg is to be built, which will develop power from the rivers Semis and Lesse. British engineers in a position to quote for the plant, machinery and equipment required in the scheme will, it is stated, be given every opportunity of submitting estimates. A total expenditure of 150 000 000 frs. is anticipated. The decision of the Luxembourg Government is shortly to be announced.

The foundation stone for the completion of the new wing of the ST. PANCRAS electric power station, in Great College Street, St. Pancras, London, was laid on Tuesday, by the Mayor.

Parliamentary Intelligence.

Ayr Electricity Bill.

The case for the promoters of this Bill continued on the 16th inst., when MR. J. H. RIDER was recalled and gave further evidence. He said that the raising of the dam at Loch Doon from five to ten feet would increase the cost by £11 500, and that would mean £600 or £700 more per annum for operating costs. That extra cost would destroy the economic advantages of the scheme.

For Kilmarnock Town Council, who opposed the Bill, MR. C. P. SPARKS, consulting engineer, stated that in his opinion some of the charges given by Mr. Rider were underestimated. He thought there should be added to the cost an extra sum of £29 000. The main objection to the scheme was the limited output due to the small catchment area. Ayr could not stand alone for 2½ years until the larger scheme was available; during that time provision must be made for an additional supply of electricity. It would be more economical to get the additional supply from Kilmarnock, instead of proceeding with the Loch Doon scheme. The municipal undertaking at Kilmarnock had been an economic success.

In cross-examination witness admitted that the generating station at Kilmarnock was no bigger than was required for their own area. They could supply Ayr, but they would have to increase their plant. He agreed that the smallness of the scheme was no reason why it should be objected to.

MR. W. COLLIER BEXON, electrical engineer to the Burgh of Kilmarnock, said that in 1920 negotiations were opened between Kilmarnock and Ayr as to the former supplying electricity to the latter burgh. Terms of agreement were drawn up in November, 1920, but were never executed. In the expectation that they would be called upon to supply Ayr with electricity they made certain alterations to their plant. He agreed that the Loch Doon scheme was not an economical one; there was not sufficient water to deal effectively with the district and the expenditure proposed was an extravagant figure.

On Wednesday MR. TYLDESLEY JONES, for Ayr Corporation, put in a new clause providing that in the carrying out of the works all reasonable regard should be had to the preservation of the beauty of the district.

MR. MORTON, consulting engineer, said he estimated the capital cost per kW of the Grampian electricity scheme at £108, and of the Lochaber water power project at £56, including the cost of the Parliamentary proceedings. The proposed croys in the stream were ingenious in theory, but he was afraid they would not work out in practice. A flow of 4 000 000 gallons per day would give a depth at one fixed point of only 2½ in., while 6 000 000 gallons would give about 3¼ in. The compensation water was absolutely negligible, but he agreed that the extra yield of water secured by raising the dam on Loch Doon to 10 ft. would not compensate for the extra cost.

Many local witnesses were called in opposition to the Bill, and on the 18th inst. the Committee passed the preamble, subject to the minimum average flow of water in the river being 8 000 000 gallons per day instead of 6 000 000 gallons which the promoters were prepared to concede, and that the clause dealing with the amenities of the district should be approved by the Lord Chairman.

During the sitting for the adjustment of clauses the promoters agreed to a proposal of the Doon Fishery Boards that there should be a minimum flow of 13 500 000 gallons in the tail-race off the mills of the river Doon to ensure a good salmon run, but the claim of the Marquis of Ailsa for the minimum flow of 36 000 000 gallons to maintain full water power for the riverside mills was disallowed, as was a claim for the fencing of the Doon reservoir.

Grampian Electricity Bill.

In reply to a question by Mr. Briggs, the CHANCELLOR OF THE EXCHEQUER (Sir Robert Horne) stated in the House of Commons last week that if a guarantee was given under the Trade Facilities Act the Advisory Committee appointed under that Act would scrutinise the prospectus, and their approval would have to be obtained before the prospectus was issued, so that there was no danger of the public being misled as to the form of the State guarantee.

On the Report stage of this Bill on Tuesday,

MR. BRIGGS moved its rejection. A letter from the Trade Facilities Advisory Committee was put in as evidence before the Committee which considered the Bill, promising a State guarantee of part of the capital to be raised by the promoters. He took exception to that particular guarantee because the assets of the Grampian Electricity Supply Company were not such as warranted it; they were not those of well-established businesses, but were only waterfalls and salmon fishing. He also objected to the guarantee because the scheme was highly speculative.

MR. ORMSBY-GORE, as Chairman of the Select Committee to which the Bill was referred, hoped the motion for rejection would not be pressed, though he agreed that the letter was an improper one. The Bill ought to be considered on the merits of the actual proposal which it contained. It would be advisable in future, before any guarantee was given, that the Trade Facilities Advisory Committee should wait until the Committee stage of the Bill was completed. In his opinion the scheme was as good a one as was likely to be produced for the development of water power in the Highlands.

MR. HILTON YOUNG and others supported the Bill, and the motion for its rejection was defeated by 185 votes to 78. The Bill was then ordered for third reading.

Workmen's Compensation.

We are likely to have a BILL FOR AMENDING THE WORKMEN'S COMPENSATION ACTS this year, for the House of Commons have unanimously passed the following resolution: "That in view of the unsatisfactory state of the law relating to workmen's compensation and of the fact that the War Additions Acts expire at the end of the year this House is of opinion that a Government Bill to amend the Workmen's Compensation Act, 1906, should be introduced and passed during the course of this Session."

In the course of the debate, the HOME SECRETARY (Mr. Shortt) said he did not believe that a single hon. member would allow the War Additions Acts to lapse without anything being put in their place. They must either pass new legislation this Session or include the War Additions Acts in the Expiring Laws Continuance Bill. He did not pledge the Government to any detailed reform which had been advocated. All agreed that the maximum amount of compensation was inadequate, but there was by no means unanimity of opinion as to what the sum should be or as to compulsory insurance and State insurance. There were many points in the report of the Departmental Committee which were highly controversial, and it might be very difficult for the Government when introducing a Bill, as he hoped they would be able to do, to deal with those points. With a view to securing agreement between all concerned, he had approached men representing the employed and the employers, and had put forward certain proposals as a basis of discussion.

Telephone Apparatus.

In reply to CAPTAIN TERRELL (House of Commons, May 22) Mr. Kellaway said that there was now no scarcity of telephone materials, and generally no difficulty was found in dealing promptly with applications for telephone service; but there were still a few localities where from various causes it had not been possible yet to complete the cables which were necessary in order to meet the demands for telephone service. He would be glad to investigate any case that was brought to his notice of an application which had been outstanding for a considerable time.

Safeguarding of Industries Act.

In a written reply (House of Commons, May 16) to DR. MURRAY, who asked the amount of duty collected on various scientific instruments and appliances under the Safeguarding of Industries Act, SIR ROBERT HORNE stated that £946 had been collected on electrical instruments (other than telephonic and telegraphic) and commercial instruments (including ammeters, voltmeters, etc.); £31 on house service meters, £211 on scientific instruments, and £5 555 on electro-medical apparatus, X-ray tubes, wireless valves, vacuum tubes and X-ray apparatus.

The Severn Scheme.

In reply to Mr. MILLS (House of Commons, May 16), MR. ARTHUR NEAL said it was not possible, owing to the financial position and the necessity for drastically curtailing the expenditure of Government Departments, to set up the Technical Commission recommended by the Water Power Resources Committee to consider the possibility of utilising the tides in the River Severn for the generation of electricity.

Bulk Supply Powers of Undertakers.

An interesting conflict of opinion has arisen between HAMMERSMITH (London) Borough Council and the Electricity Commissioners in regard to the Council's proposal to give a bulk supply of electricity to Ealing Corporation, and it is probable that the matter may lead to legal proceedings.

It appears that in November last the Borough Council agreed to give a bulk supply for general purposes to Ealing on terms and conditions which were to be approved by both Councils, and application was made to the Electricity Commissioners for the sanction to the proposal. The matter has since been the subject of correspondence between both Councils and the Commissioners, and conferences have also been held with the Commissioners and representatives of the Councils. The Commissioners now state that, after consideration of the circumstances, they are unable to approve the proposed agreement. On the 3rd inst. a joint meeting of the Ealing and Hammersmith Electricity Committees was held, and directions were given for steps to be taken to test the powers of the Commissioners to refuse their approval of the proposal.

While we are unaware of the reasons given by the Commissioners for their refusal and of the full facts of the case, it is doubtful if the Council can succeed in any proceedings against them, for Sec. 19 of the Electricity (Supply) Act distinctly states that any two or more of the authorised undertakers within the locality (of any Electricity District) *may, with the approval of the Electricity Commissioners* . . . . enter into and carry into effect arrangements for mutual assistance with regard to the giving and taking of a supply of electricity, etc. The Commissioners have hitherto been so business-like and reasonable in their decisions that we venture to think there must be good engineering or economic reasons for their present attitude. At all events, we should deprecate litigation on such a point as that which has arisen.

Legal Intelligence.

An Undue Preference Allegation.

On Tuesday Mr. Justice Swift delivered his reserved judgment in the action brought by the Westminster Electric Supply Corporation against Wykeham Studios, Ltd., for the recovery of £82 18s. 5d. for electricity supplied for their art photography business. Defendants admitted liability for part of the sum claimed but denied they were liable for the rate charged.

In giving judgment his Lordship said:—Defendant company admitted liability for £48 5s. 10d.; judgment for that amount had been signed and liberty was given to defend as to the balance of the claim. It was admitted that the amount claimed was accurate if plaintiffs were entitled to charge the rate they had done. The plaintiffs were supplying electricity under the provisions of the Westminster Electric Lighting Order (1889) in the area mentioned in the first schedule of the Order. For many years plaintiffs had been in the habit of supplying electricity at two different rates of charge, one rate for lighting and a lower rate for purposes other than lighting and supplied through a separate meter and known as power rate.

Defendants have been using electricity for a photographic arc lamp, and it was admitted that the electricity had been used by defendants for purposes other than general illuminating purposes. Plaintiffs sought to charge defendants at a higher rate than the maximum rate stated by them to be payable for electricity used for power, and defendants object that the current having been taken and used by them for power purposes, that is to say for purposes other than lighting and through a separate meter, they were not liable to be charged more than the maximum rate for power. He found as a fact, on the admissions made, that the electric current used by defendants was used for power purposes and not for lighting, and that it should be charged for at the power and not at the lighting rate. That, however, did not dispose of the action, for plaintiffs contended that even if they were under the circumstances compelled to treat defendants as taking electricity for power purposes only, they might still charge them at the rates which they had done, that is to say 7d. per unit for the quarters ending midsummer and Michaelmas, and 4d. for the quarter ending at Christmas 1921. The right of plaintiffs to so charge was dependent upon the construction of section 19 and 20 of the Electric Lighting Act, 1882.

Having quoted both sections, his Lordship referred at length to the judgments in Metropolitan Electric Supply Co. *v.* Ginder, the Attorney General for Victoria *v.* Melbourne Corporation, the Attorney General *v.* Long Eaton Urban Council, and the Attorney General *v.* Hackney Borough Council. He thought the result of those decisions was that where current was supplied on two different systems, the choice of which was left to the consumer, there was no infringement of sections 19 and 20, and that as between customers of each system the undertakers were entitled to differentiate as to price provided that the special circumstances of each customer were regarded. But it was contended in the present case that defendants using the current for power purposes had been charged more than the rate which was fixed and advertised by plaintiffs as being the rate for current supplied for power. He did not see why this should not be done, if regard was had to the special circumstances of those who were charged at the higher rate and if a proper differentiation could be made between them and others who were being supplied with electricity for power in the same area, provided that the undertakers did not charge more than the amount which was fixed by the Act, or which for the time being was agreed upon between them and the consumer. He could not see why they should not be allowed to charge a consumer more if the circumstances under which he was taking power were not similar to those of other persons who were taking it.

In that case, photographers, speaking generally, were not taking current for power under similar circumstances to other consumers. Their lamp was not burning regularly and for fixed hours during the day or night, but was intermittently used as occasion necessitated for the taking of particular photographs, and he thought that the undertakers were entitled to say that, although their ordinary charge to persons using current for power was 2d. per unit, they would charge a higher rate to persons who took current for use in a photographic arc lamp. At any rate he saw nothing in the sections of the 1882 Act referred to or the decisions upon them which was inconsistent with that view. It is clear that plaintiffs were under no agreement to charge defendants other than the rates which they did, and defendants had ample notice of the rates which they would be charged. All photographers in the area had been treated in the same way, and under the circumstances there would be judgment for plaintiffs for the amount claimed with costs.

Improper Use of Electricity.

Last week the Southend magistrates had before them three charges of improperly using electricity, and in two of them alternative charges of fraud were alleged. P. Morgan and Co. were summoned under Sec. 12 of the Electric Lighting Act, 1882, for improperly using electricity within the last six months at their premises; and there was a similar summons against Marshall Rowland Cook, but it was also alleged alternatively that during the past six months he consumed electricity fraudulently, contrary to Sec. 10 of the Larceny Act, 1916. A similar charge of fraudulent consumption of electricity during the past six months was made against Harris Goldstein.

The cases against Morgan and Co. and Goldstein were adjourned for three weeks.

The Asst. Town Clerk (Mr. Beresford) said that Cook, who pleaded guilty, had a supply on the contract rate for light, with a separate supply for power for hairbrushing and for sharpening razors. Requiring more light in the selling portion of the shop, instead of applying for an increased supply, he tapped the power circuit, with the result that he was paying the power rate for that light (3¾d.), instead of the lighting rate of 8d. per unit. He did not inform the Corporation of what he had done, but when spoken to by one of the inspectors, he said: "All right, old man. You need not take the matter any further, I know I have done wrong."

Evidence having been given by a meter inspector and by the meter superintendent, defendant said he knew nothing about electricity. He had the power meter installed some years before the war, and having been away in the Army for seven years, he forgot the terms. He agreed with the statements concerning the lamp, and wished to apologise.

The Bench came to the conclusion that Cook had improperly—not fraudulently—used the light, and fined him £5.

Is a Tramcar a Carriage?

Last week the Bradford Stipendiary Magistrate (Mr. Beaumont Morice) gave his reserved decision on a charge against Mr. S. Goldthorpe, brought under section 28 of the Town Police Clauses Act, for not keeping a motor wagon on the right or off side of the road when passing a certain carriage.

The defence was that the tramcar was not a carriage within the meaning of the Act, but Mr. Morice held that he was bound by a decision of the High Court that a tramcar was a carriage. Having regard to the fact, however, that in the present case two tramcars were on their respective lines, and to the conflicting evidence, he was of opinion that the circumstances were a sufficient reason for the deviation.

The case was therefore dismissed, with costs.

Institution Notes.

The list of successful candidates for the A.M.I.E.E. Examination held last month has now been published. Thirty-six candidates passed the whole examination, sixteen passed Part II only, and two passed Part I only. Results relating to candidates who sat for the examination abroad will be published later.

In the examination for officers of the Corps of the Royal Engineers, fifteen passed the whole examination, one passed Part I only. Of the officers of the Royal Corps of Signals two passed the whole examination.

Members of the Institution of Mining Engineers from Glasgow, Edinburgh, the Lothians, and other centres, paid a visit of inspection last Saturday to the works of the British Electric Plant Co. at Alloa. The visitors were conducted through the works by Mr. F. G. Warburton, of the directorate; Mr. A. S. Murdoch, the works manager; and Mr. R. Wright, the secretary; and great interest was taken in the various departments.

The result of the ballot for the election of officers and new members of Council of the Institution of Electrical Engineers for 1922-23 is as follows:—*President*, Mr. F. Gill; *vice-Presidents*, Dr. W. H. Eccles, Mr. A. A. Campbell Swinton; *Hon. treasurer*, Sir James Devonshire; *ordinary members of Council*, Mr. J. W. Beauchamp, Mr. R. A. Chattock, Mr. F. W. Crawter, Mr. D. N. Dunlop, Major K. Edgcumbe, Mr. A. F. Harmer, Mr. W. R. Rawlings.

The fourth Quadrennial Gustave Canet Lecture entitled "The Railway Act 1921," will be given before the Junior Institution of Engineers by Sir Eric C. Geddes, on Thursday, June 1, in the Lecture Theatre of the Institution of Electrical Engineers, Victoria Embankment, London. The chair will be taken at 7.30 p.m. by Mr. C. H. Wordingham, President of the Institution. Tickets may be obtained from the Secretary, 39, Victoria Street, S.W.1.

South Wales Engineering Exhibition.

The Council of the South Wales Institute of Engineers have decided to hold an Engineering Exhibition at the Drill Hall, Cardiff, during the week commencing November 20 next. Each morning a conference will be held at the Institute, when short papers on various subjects connected with the exhibition will be read and discussed. Offers of such papers will be welcomed.

The exhibition will be divided into six sections, including:—(I) Scientific, Measuring and Recording Instruments; (II) Water-Softening and Cooling Plant, Boilers and Equipment, Oil Burners, Pipes, etc.; (III) Electrical Section: Switchgear, Cables, Controllers, Overhead Lines, Electrical Tools and other appliances, Small Motors, Electric Cranes, Telephone and Wireless Apparatus; (IV) Mechanical Transmission of Power, Bearings, Clutches, Gearing, etc.; (V) Workshop Appliances: Machine Tools, Pneumatic Tools, etc.; (VI) Mining and General Industrial Section.

The British Engineers' Association has been entrusted with the task of organising the Shipbuilding, Marine, Mechanical and General Engineering Section of the British Empire Exhibition to be held in London in 1924. Full particulars, plans, and forms of application for space will be available for issue at an early date. Enquiries should be addressed to D. A. Bremner, Director, The British Engineers' Association, 32, Victoria Street, London, S.W.1.

Electricity Supply.

At a meeting of the HEYWOOD Electricity and Tramways Committee it was reported that the consumption of electricity for lighting and power purposes during March last was 150 328 units, as against 109 755 units for the corresponding period of last year, showing an increase of 40 573 units, or 36·96 per cent. There was a loss on the working of the Electricity Department for the past year of £1 047, due to the coal strike and the slump in trade.

To celebrate the reduction of coal consumption to one ton per 1 000 units, Ald. C. Hardman, chairman of OLDHAM Electricity Committee, entertained members of the Committee and staff to dinner last week. In the course of a speech he recalled the fact that in 1913–44 the coal consumption was 6¾ lb. per unit, whereas it was now about 2½ lb., and he hoped it would be brought down to 2 lb. or less. Although they had expected an adverse balance on the year's working, they had come out with a four-figure profit, and a reduction of prices would be considered shortly.

HAMMERSMITH FINANCE COMMITTEE recommend the Council to apply to the Electricity Commissioners for sanction to borrow additional sums of (*a*) £61 590 in connection with the extension of the electricity generating plant; (*b*) £7 057 relating to the provision of the No. 16 (Stirling) boiler, and (*c*) £3 717 in respect of the erection of the building for the powdered fuel plant. The Electricity Committee recommend that a sum of £1 000 be set aside out of the surplus revenue of the electricity undertaking for the financial year, 1921-22 for the purchase and hiring out of electrical apparatus.

The annual report of BARROW Electricity Undertaking shows a net profit of £374 compared with a deficit in the previous year of £2 500. The income from the sale of electricity was £11 798 below last year, but general lighting and heating receipts advanced by £4 194, and tramway supply by £381. There was a drop of £16 373 in power and industrial supply. Public lighting has increased by £1 172, and rents of motors and apparatus on hire by £1 121. Working expenses are £17 653 less than last year, chiefly due to a decrease in the coal bill of £13 409. The total revenue for the year was £77 122, and the working costs £51 010. The capacity of the plant at the end of the year was 7 025 kW, and the number of units sold 6 886 504, against 9 282 017 units in the previous year

New Schemes and Mains Extensions.

Warrington Corporation is now supplying electricity to STOCKTON HEATH, the formal switching on of current taking place from the sub-station on Monday, May 22.

Accrington Corporation have applied to the Electricity Commissioners for a Special Order to extend the Corporation's area of electricity supply to the Urban District of OSWALDTWISTLE. Any objections must be sent to the Electricity Commissioners by June 19.

The Electricity Commissioners have sanctioned the borrowing of £13 500 by SHREWSBURY Electricity Committee for extensions to the electricity works, and have intimated that they are prepared to consider the sanctioning of the borrowing of any further sum, which may be found necessary when the cost has been approximately ascertained.

HOYLAKE Electricity Committee propose to obtain a loan of £1 000 for mains and services. The Committee have gone back to the pre-war condition of giving 15 ft. free service to consumers, and where extensions of mains are not involved work will be proceeded with without awaiting the Committee's consent. There are now 2 000 consumers, or 150 more than twelve months ago.

The Electricity Commissioners have declined to sanction a loan of £5 000 applied for by GRAYS Urban Council for extensions at the electricity undertaking, and recommend the Council to wait until they can obtain a supply from the proposed new station at Barking of the County of London Electric Supply Company. The urgency of the situation with regard to the continuity of supply during the coming winter is to be explained to the Commissioners by the Council.

PRESTON Town Council has received formal consent of the Electricity Commissioners to the establishment of a generating station at Penwortham, with an initial capacity of 20 000 kW. The Committee are applying for the Commissioners' consent to the establishment of a further generating station, and to the borrowing of £416 450 for the purpose. The Town Clerk has been authorised to take the necessary steps, in conjunction with the Blackburn authority, for the presentation of a scheme for the Mid-Lancashire Electricity District to the Commissioners at the local inquiry.

Alteration of Charges.

The charges for electricity at CREWE are to be reduced by 12½ per cent.

WALLASEY Electricity Committee have decided to exercise their powers under the Electric Lighting Act regarding minimum charges. Under the Act the Corporation is entitled to charge a minimum of £2 13s. 4d. per year to lighting consumers.

PRESTON Electricity Committee have decided to allow 10 per cent. discount to lighting consumers in Preston and Fulwood on meter readings as from the June quarter, and to increase to 15 per cent. the present 5 per cent. discount to power users.

Electric Traction.

ROTHERHAM Corporation has applied to the Minister of Transport for permission to run motor-omnibuses on certain routes.

HEYWOOD municipal tramways were run at a loss of £2 431 last year. In 1914 the working cost per car mile was 3½d.: it is now nearly 1s.

It is stated that the ELECTRIFICATION of the London and North Western Railway between CHALK FARM and EUSTON will be completed by the end of next month.

The experiment made by ABERDARE Urban Council in the use of one-man tramcars and omnibuses has proved satisfactory, and the system is being extended to the trolley omnibus cars.

The annual conference of the managers' section of the BRITISH MUNICIPAL TRAMWAYS ASSOCIATION will be held in Glasgow on June 15 and 16. The topics of discussion will be chiefly questions of car maintenance.

A revision has been made this month of the fares charged on the BRISTOL tramways. Under the new rates children under twelve are carried at reduced prices, and cheaper fares have been introduced on certain routes for all passengers.

By a majority of 7 499, NEWPORT ratepayers, on Saturday, decided upon the introduction of a Sunday service of tramcars. Over 50 per cent. of the electors went to the poll, which was preceded by 19 public meetings. The new service will start next Sunday.

The BIRMINGHAM Corporation Electric Tramways Department made a net profit last year of £192 500, but this sum will be absorbed by the programme of reconstruction work undertaken during the past year by the department. The passengers carried numbered 183½ millions as against 218 millions in the previous year.

Serious corrugation has set in on CARDIFF tram tracks. At a meeting of the Tramways Committee last week, the tramways manager (Mr. R. H. Horsfield) said it was apparent even in the new track which had been laid. The problem was a serious one, and must be dealt with. The attention of the city engineer had been drawn to the matter, and it was decided to await his report.

The new EXPRESS TRAM TRACK IN LEEDS from Harehills to Oakwood was officially inspected last Friday by Major Hall, R.E., of the Ministry of Transport, and on Sunday was opened for traffic. The chief interest in the new system is that for the first time in the city it supplies an example of tramcars run on rails and sleepers, the cost of this particular form of construction being much less than that of laying down concrete beds in the centre of the road. The cost of renewal will also be less.

Alderman Higham, chairman of the ACCRINGTON Tramways and Electricity Committee, informed the Town Council on Monday that, compared with a loss on the tramways last year of £2 008, they now had a balance on the right side of £5 300. After contributions to the appropriation fund they would be able to place £2 234 to the repairs and renewals fund, which now stood at £30 000. The saving had been in general repairs and maintenance of track, which had cost only £10 000, compared with £17 000 last year.

A recommendation has been sent to all the tramways undertakings in the Midlands, including Nottingham and Leicester, by the Midland Area Industrial Council for the Tramway Industry, urging the adoption of the COVERED-IN (OR VESTIBULE) FRONT FOR ALL TRAMCARS, as it is found that the dust caused by the increased motor traffic causes the drivers, when too much exposed to the weather, to suffer from bronchial and eye troubles. The executive of the Municipal Tramways Association have also had the matter under discussion with a view to finding the best type of vestibule to adopt.

Members of LIVERPOOL Tramways and Electricity Committee paid a visit of inspection last Thursday to some of the most important undertakings of which they have charge, including the Lambeth-road works, where a large number of tramway cars are being renovated, and eight new ones of the latest type being built, and the Lister-drive Power Station. The new tramway in course of construction from the city boundary at Knotty Ash to Prescot was partly travelled over, and the Aigburth-road improvements were also inspected. At the luncheon at the Midland Adelphi, Mr. Frank Wilson, chairman of the Committee, who presided, gave a résumé of the year's work. At the Lambeth-road works (he said) a large amount of renewals were being steadily carried out. They had spent £692 738 in this connection during the last three years, and that was one reason why they had had to go in for increased fares. Many of the cars were twenty years old, and a number of them ought to be scrapped. They had now 618 cars in service, of which 450 were twenty years old. He thought the increased fares were justified, for they were now doing very well, and before long he hoped they would have a clean slate. Then they might talk of cheaper fares. They hoped, indeed, to do this later in the year. With regard to the Prescot route, they would be running right through on the new line in three months' time. Their electricity undertaking had increased greatly, and the area of supply now covered the whole of the city from Garston to Aintree. Negotiations were nearing completion to take over the supply in Bootle, Waterloo and Great Crosby, and to supply Hightown and Formby.

Business Items, etc.

Mr. E. F. Turner, for many years works manager for Brind, Gillingham and Co., has started business as an electrical engineer at 20, Banbury Road, Oxford.

Mr. Eric Toft, having retired from the firm of Radford and Toft, electrical engineers, 8, Station Buildings, Altrincham, the business will be continued by Mr. Luke Radford under the style of L. Radford and Co.

Mr. F. Kent, who was formerly with Crompton and Co., has been appointed manager of a branch business at Priory Road, High Wycombe, established by Walters, Dobson and Co., electrical and general engineers, of Sheffield.

Mr. Duncan White, lately with Brooks and White, has now joined the Hotpoint Electric Appliance Co., London, W. Mr. White will deal with applications and problems relating to heating and cooking apparatus and will also deal with maintenance and repair work.

The Manifoldia (Regd.) System, designed by Mr. A. H. Human, for ensuring perfect supervision and record keeping of electrical installations, is on view at the stand of Manifoldia, Ltd., at the Efficiency Exhibition which opened at Bingley Hall, Birmingham, yesterday (Thursday), and will remain open till June 3. We hope to give further details of the system in an early issue.

Plant and Supplies, Ltd., announce that they have purchased the business of Mr. Ashley Pope, Toddington, near Dunstable, and that he has been appointed managing director. Plant and Supplies, Ltd., are the sole agents and distributors for London, the Home Counties and the southern portion of England for the "Sceando" lamp which is manufactured throughout in this country in both the one watt and half watt types.

In order to cope with their increasing business in the south of England Ward and Goldstone have opened extensive premises at 8a and 9, Great Chapel-street, Oxford-street, W.1 (three minutes from Tottenham Court-road Tube Station), where in future all London and district orders will be dealt with. Mr. J. S. Child (ex joint sales manager to the Edison Swan Electric Company) has been appointed to represent the firm in this district.

Telegraph and Telephone Notes.

The reduction in telephone charges, foreshadowed in Mr. Kellaway's speech in the House of Commons on May 4, and given in our last issue, will come into operation on July 1.

The cable ship "Monarch" which has been at Sheerness Dockyard undergoing her first refit since the war, has left Sheerness to resume duties. Arrangements have been made for the "Alert" to refit at Sheerness.

Hull Corporation Telephone undertaking for the year ending March 19 last shows a net profit of £3 938. The undertaking has to pay over £10 000 royalty annually to the Government, and up to date £74 000 has been paid under that head.

The Commercial Cable Company notifies that on and after May 22 deferred messages between Great Britain and Cape Breton, Nova Scotia, New Brunswick, Prince Edward Island and the provinces of Quebec and Ontario will be reduced to 4½d. per word

It is reported that the Indo-European Trust has obtained the concession for the exploitation of the telegraph system of Russia. In addition to this, it is stated that the company will take over the main cable from Odessa to Constantinople and the line from Odessa to Kerlch, Tiflis and the Persian frontier.

In connection with the scheme for the construction and laying of two submarine telegraph cables between Germany and America, orders have been placed with German firms for the manufacture of the cables, which will be operated by the Deutsch Atlantische Telegraphen Gesellschaft. This company has recently been reorganised; its capital has been increased to 40 000 000 marks and agreements have also been made with American cable companies.

The Chinese Telegraph Administration announces that telegraphic communication between the Far East and Europe via Siberia has been re-established. Telegrams intended for transmission by this route should be marked "via Holampo." They will be accepted for the following countries:—All countries in Europe, Russia in Europe, Russia in Asia west of, and including, Habarovsk, Outer Mongolia (Urga). Rates are as follows:— Europe, $1.40; Russia in Europe, $0.75; Russia in Asia, $0.55; Outer Mongolia (Urga), $1.25.

A five years' agreement has been entered into by the London County Council with the London Telephone Service for the hire by the Council of an automatic internal telephone system at the new County Hall. The electric power required in connection with the exchange apparatus is to be supplied by the Council, and the rent to be £1 734 a year for any number of lines up to 400, and £4 a year for each additional line ordered up to a total of 900 lines, together with the usual charges for wiring more than the normal length, to be paid by the Council.

Personal and Appointments.

Sir Charles Addis has joined the board of the Eastern Telegraph Co.

Sir Dugald Clerk has consented to become hon. president of the Cardiff University College Engineering Society.

Mr. Oxenham, of Launceston, has been appointed engineer to Bideford and District Electric Supply Co. He has been in charge of a similar plant at Launceston running on sawdust fuel, which is also to be used at Bideford.

Mr. J. W. Rodger, who for some years has been chief transformer designer and assistant manager with Ferranti, Ltd., has severed his connection with this firm in order to take up a similar position with the Hackbridge Electric Construction Co.

We are asked to state that any business friends of Mr. C. D. Falcke, managing director for the past six years of The B.E. Co. (of London and Birmingham), Ltd., now in voluntary liquidation, and proprietor of the original business in Birmingham for a period of nearly twenty years, who wish to communicate with him, may do so by addressing him at the Engineers' Club, Coventry-street, W.1. For purely personal matters his telephone number is: Paddington 5069.

Mr. C. G. Schluederberg, of the Westinghouse Electric Co., has been elected president of the American Electro-Chemical Society. Mr. Schluederberg belongs to a number of engineering and other societies and has been particularly active in the American Electro-Chemical Society. He has also served on several committees of the American Institute of Electrical Engineers. He has published a number of articles covering original research work and electro-chemical activities and developments.

Wireless Notes.

A meeting of an international committee of shipowners is being held in London this week to consider what changes, if any, should be advocated in the present system of wireless communications respecting ships in distress.

Glasgow and District Radio Club report a considerable addition to their membership and an increased attendance at their meetings. New premises have been obtained at 200, Buchanan Street, and next session meetings will be held weekly.

Mr. J. H. Hammond, junr., an American, claims to have perfected apparatus to prevent a radio station from receiving messages except those intended for it. He further claims that "the same wave can be made to carry several messages at the same time and that both voice and code may be transmitted."

Subject to the approval of the Postmaster-General an agreement has been made, we understand, between the Metropolitan Vickers Electrical Company, and the Radio Communication Company, for the joint establishment and operation of wireless telephone broadcasting stations throughout Great Britain.

A successful experiment in wireless communication between the earth's surface and places in coal mines was recently made by a party of geologists and scientists in the Blue John Mine, Castleton. A receiving set was taken into the cave known as the Lord Mulgrave's Dining Room about 280 ft. from the entrance and a quarter of a mile in any direction from the open. Here a 50 ft. aerial was suspended across the cave and with a small apparatus signals were received clearly from Poldu, in Cornwall, from a station near Berlin, and from other high power transmitting centres.

Representatives of twenty firms attended the conference last Thursday at the General Post Office to discuss the arrangements to be made for broad-casting matter (including music) by wireless sets. It was recognised generally, the official report of the conference states, that, in order to avoid interference, broadcasting stations would have to be very limited in number. Some of the representatives thought that not more than eight could work simultaneously in Great Britain, using the power (1½ kW) and the band of wave lengths (350-425 metres), allowed for the purpose, without such interference as would produce practical chaos. It was also recognised that the provision of a suitable daily programme at the various stations would be expensive, and that it was important in the interests both of the public and the manufacturing industry that the continuity of the service and the maintenance of a high standard in the programme should be ensured. The best means of attaining these objects seemed to lie in co-operation among the firms concerned, and it was suggested that one or possibly two groups should be formed, which should become responsible, both financially and otherwise, for the erection and maintenance of the stations and the provision of suitable programmes. In accordance with these suggestions it was arranged that the representatives of the various firms should collaborate in the immediate preparation of a co-operative scheme, or at the most of two such schemes, for consideration by the Post Office authorities.

The "Daily Mail" announced last Friday that the Ideal Home Exhibition will be held again next March, instead of waiting until 1924, as previously proposed. Our readers will do well to make early application for space.

Imperial Notes.

The Metropolitan-Vickers Electrical Company have obtained a contract for the supply of plant and equipment for the electricity supply scheme for JUBBULPORE (India).

KANDY (Ceylon) Municipality is taking over the electrical generating plant of the Colombo Gas and Water Works Company at Kandy. The purchase price is R. 1 50 000 (£10 000).

Grenville Shire Council contemplate the provision of electricity supply works for LINTON (Victoria), and expert advice is being obtained on the possibility of using water power for generating electrical energy.

It appears that the German experts engaged by the Victorian Government in connection with the MORWELL BRIQUETTE SCHEME are now unwilling to land in Australia. They have, however, been assured that they need fear no hostile demonstrations.

"Indian Engineering" says certain home firms were in communication with the CEYLON Government with a view to entering into partnership with the Government in relation to the proposed hydro-electric scheme. It is now stated that the Government has decided to carry out the work itself, with the assistance of a special staff of engineers engaged from Great Britain.

The Royal Commission appointed by the Ontario Provincial Government to investigate the QUEENSTON-CHIPPAWA HYDRO-ELECTRIC SCHEME of the Hydro-Electric Power Commission of Ontario consists of the following: Mr. Walter D. Gregory (Chairman), Mr. M. J. Haney, Mr. L. Harris, Mr. J. A. Ross and Dr. R. A. Ross. The chairman is a lawyer, and there are two engineers and two manufacturers on the Commission.

In an article on Trolly Omnibuses in "Indian Engineering" it is suggested that RAILLESS TRACTION might be adopted in certain cases of approaches to hill stations, where good roads exist. At GAUHATI-SHILLONG, for instance, there is a first-class road, and hydro-electric power could be provided cheaply in the locality. With cheaper and quicker transport than that now available, the possibilities of Shillong are believed to be unlimited.

Foreign Notes.

The third INTERNATIONAL CONGRESS OF CONSULTING ENGINEERS, organised by the Federation Internationale des Ingenieurs Civils, will take place at Warsaw from the 28th to the 31st inst.

According to the 1920 census, there are 27 077 electrical engineers engaged in the practice of their profession in the UNITED STATES. This compares with 15 278 shown in the 1910 census. In 1920 there were 212 964 electricians, as compared with 120 241 in 1910.

It is reported that arrangements have been made to merge the Dubilier Condenser Company of America, the Federal Mica Company and the Cambridge Manufacturing Company into one corporation, to be known as the DUBILIER CONDENSER AND RADIO COMPANY.

Forty American investment bankers who are at present in France have come over, the "Chicago Tribune" (Paris edition) states, primarily to inquire into some HYDRO-ELECTRIC PROJECTS ALONG THE RHONE and in the Pyrenees. The estimated cost of harnessing the Rhone is over five hundred million francs.

The supply of RADIO RECEIVING SETS is developing into a big business in the UNITED STATES. For instance, the Westinghouse Company is reported to be turning out 500 outfits a day at present, and its production capacity is to be increased to 1 000 a day. As there are several other manufacturers engaged in the same field it will be seen that the radio "craze" is very acute.

In the report of the AMERICAN ENGINEERING STANDARDS COMMITTEE it is stated that work is now proceeding on 79 distinct projects, and 160 National Associations are co-operating. During 1921 the Committee approved 15 standards, including a standard method for sampling coal, The National Electrical Code Specifications for soft or annealed copper, and the Industrial Lighting Safety Code.

An AMBITIOUS ELECTRICAL PROGRAMME has been prepared by the Superior Council of Public Works of FRANCE. It is suggested that hydro-electric generating stations of a total rating of 1 370 000 kW should be erected with a high-tension transmission system of 9 000 to 10 000 miles. The cost is estimated at 15 000 000 francs, to be spread over 15 years. If carried out the scheme will make France less dependent upon imported coal.

The shareholders of the ILLINOIS CENTRAL RAILROAD COMPANY have authorised the issue of $50 000 000 preferred stock in order to finance the company's Chicago terminal. Over $80 000 000 will be spent on the work, and the suburban service must be electrified by 1926. Further time is allowed for other portions of the scheme, but through passenger service must be operated completely by electric service by 1939. Mr. A. S. Baldwin, vice-president, in charge of electrification, and Mr. Hugh Pattison, chief engineer, are visiting Europe in order to study Continental systems.

An important new company, entitled the Societá Italo-Americana per la Elettrotrazione, has been formed in Italy for the purpose of constituting an ASSOCIATION OF ITALIAN POWER COMPANIES AND AMERICAN FIRMS in order to promote the generation and distribution of electricity and the construction and working of electric railways and tramways. The principal object of the company is the adoption in Italy of American systems of continuous current traction at high potential, and some Italian engineers have been sent to the United States in order to study electrification methods.

An ENGINEERING STANDARDS COMMITTEE of 70 members was recently formed in Japan, and much useful work has already been undertaken, including investigations into electric wires and cables and electric motors. The Minister of Agriculture and Commerce is president of the Committee. There are seven secretaries, all engineers in government departments. The "Electrical World" states that there are now national standardising committees or associations in the following countries: Austria, Belgium, Canada, Czechoslovakia, France, Germany, Great Britain, Holland, Italy, Japan, Norway, Sweden, Switzerland and the United States.

Breaking records is one of the pleasant pastimes of our American friends, and judging from the statistics published in the "Electrical World," the supply industry is out to keep itself well "in the limelight," or perhaps we ought to say the electric light. During February the AVERAGE DAILY OUTPUT OF ELECTRICITY IN THE UNITED STATES was 132 720 000 units, or 1 840 000 units more than the previous highest record, in December last. Another feature of the month's record was a drop in the lighting loads, owing to the longer days, and an increase in industrial power requirements. During 1921 the total output was 43 905 000 000 units against 45 678 000 000 in 1920, but notwithstanding this drop the total revenue showed an advance of 7 per cent.

The total consumption of ELECTRICITY IN ITALY in 1919-20 for lighting power and traction was 3 826 562 180 units, or an average consumption of about 9·5 units per head of the population. There is great activity in the development of water power, and even at present most of the plant is hydro-electric. In Lombardy, the most highly developed part of the country, there are plants of 603 000 kW, but less than one-sixth are steam driven; and in Piedmont, out of 405 000 kW steam sets only account for 30 000 kW. Considerable progress has been made since the war, especially in connection with the electrification of railways and hydro-electric schemes, as the high cost and scarcity of fuel compelled attention to the development of a substitute for imported coal.

Mr. Malan, South African Minister of Mines and Industry, introduced into the Union House of Assembly last week an ELECTRICITY BILL providing for the appointment of a Commission for establishing and maintaining stations for the supply of electricity to Government and local authorities, companies, and individuals, also for an investigation regarding additional supplies and the co-ordination of existing undertakings with a view to stimulating the provision of a cheap and abundant supply of electricity. Except in the case of municipalities the Commission would be empowered under the Bill to fix prices and order a return to consumers of 25 per cent. of the surplus profits. After 38 years the Government may give two years' notice of its intention to expropriate all but municipal electrical undertakings, paying nothing for goodwill or prospective profits.

The Engineering Industry in Belgium.

Mr. R. F. H. DUKE, H.M. Commercial Secretary at Brussels, states in his annual report on the economic situation of Belgium that many of the engineering firms have profited by the slackness in trade during 1920 and 1921 to complete the reconstruction of their works damaged by the Germans and to install new equipment. At the same time attention has been given to the importance of making Belgium independent of other countries, and particularly Germany, in regard to electrical material, and during 1919 six new electrical factories were established, manufacturing conduits, switch boards, incandescent lamps, machinery and signal apparatus. The Ateliers de Construction Electrique de Charleroi, which has a capital of 40 000 000 francs, has installed entirely modern machinery and extended its works. Varied types of machinery are manufactured by this firm, from ½ H.P. motors to the most powerful alternator, with all necessary high and low tension appliances. The construction of extraction machines and sets of centrifugal motor pumps for coal mines has also been developed during the year, the production of small motors in series has been organised, and the cable works have been extended.

The Société d'Electricité et de Mécanique Procedés Thompson Houston et Carels have also extended their works; the machine tool and mounting department has been enlarged, the foundry for small parts has been doubled; and a mechanical foundry installed. Large modelling workshops have been built, and also a warehouse for general purposes. Regulators, alternators, transformers and large motors are now manufactured, while as regards the mechanical construction of Diesel motors and steam engines, it is claimed that production has reached the pre-war figure.

German competition in the electrical constructional industry is, however, states Mr. Duke, growing serious in Belgium, and the Allegemeine Electricitaets Gesellschaft have opened offices in Charleroi under the mask of a Luxemburg firm. Any sale of British technical goods in this country is exceedingly difficult owing to the high prices quoted.

The Post Office (Pneumatic Tubes Acquisition) Bill passed its second reading in the House of Commons on Monday, and was referred to a Select Committee.

Miscellaneous.

LICENSES OF RIGHT have been granted to E. L. R. Couch for Patent No. 23 454/13 for "improvements in apparatus for electrolytically cleaning articles."

INCANDESCENT ELECTRIC LAMP BULBS are not apparently included in the Coal Mines (Temporary Provisions as to Safety Lamps) Bill, and only glasses for flame lamps are to be dealt with.

The late MR. JACOB ATHERTON, director of the County of London Electric Supply Company and the South London Electric Supply Corporation has left estate valued at £20 603 (net personalty £2 328).

A CENOTAPH to the employees of the Birmingham Corporation Electric Tramways, who were killed in the war has been erected on the Tramways' Stadium, at Kings Heath, and will be dedicated by the Bishop of Birmingham on Sunday, and unveiled by Lt. Clarke of the Dorset Regiment.

At a meeting of the Council of the South Wales and Monmouthshire University College, Cardiff, the Finance Committee reported that the bequest of the late Sir Archibald D. Dawnay to the South Wales Institute of Engineers had enabled the college to offer an "ARCHIBALD DAWNAY" SCHOLARSHIP of the value of £50 a year, tenable for three years, for competition at the entrance scholarship examination held in April last.

A committee of eleven members, including Mme. Curie, Professor of Physics, University of Paris, Herr Einstein, Professor of Physics, University of Berlin, and Señor de Torres, Director of the Electrotechnical Laboratory, Madrid, have been appointed by the Council of the League of Nations to study the question of INTERNATIONAL INTELLECTUAL CO-OPERATION in conformity with the resolution passed by the second General Assembly of the League.

We regret that owing to an oversight, it was stated in our issue of April 28 that the NEW GRIMSBY EXCHANGE was the first automatic telephone installation in the country. This is, of course, not the case. Automatic exchanges at Epsom, Accrington, Chepstow, Portsmouth, Paisley, Blackburn and Leeds were all in existence before that at Grimsby, and in every case the work was carried out by the Automatic Telephone Manufacturing Company.

A METER FOR STAMPING LETTERS was tested and approved by the Post Office last week when letters at the rate of 250 a minute were post-marked, stamped, sealed, counted and stacked. These meters, it is understood, will be obtainable under license from the Post Office, and attached to specially electrically operated machines in the offices where they are to be used. Each meter has a maximum capacity of 100 000 imprints, which are paid for in advance. A new supply is obtained by taking the meter to the Post Office to be reset. After each setting the register door is locked and officially sealed.

On Thursday, May 11th, Swan, Hunter, and Wigham Richardson, Ltd., launched from their Neptune Shipyard, Walker, a TELEGRAPH CABLE REPAIRING STEAMER, constructed for the Commercial Cable Co. of New York. This vessel, called the "Marie Louise Mackay," is smaller than the "John W. Mackay," launched by the company last November. She is 246 ft. in length by 34 ft. in breadth by 24 ft. 4 in. in depth, and will be propelled by twin screw machinery. The cable will be carried in three cable tanks, placed forward of the propelling machinery, and having a total coiling capacity of about 18000 cub. ft. The machinery required for working the cable includes picking up and paying out gears, Lucas dynamometers, and a Lucas patent sounding machine, and is being supplied by the Telegraph Construction and Maintenance Company.

Fatal Accidents.

AN OPEN VERDICT was returned at the inquest held on Saturday by Sheriff Shennan and a jury into the deaths of Andrew Martin and John Chalmers, miners, who were killed by an explosion in No. 1 Pit in Viewpark Colliery, Uddingston, on April 11. The evidence showed that the explosion occurred at an electrical coal cutter in the splint coal seam of the pit. It was stated that complaints with regard to the coal cutter had been made, and that the machine had been repaired by the colliery electrician, who stated that it was in good order prior to the explosion. After the explosion the machine was found to be without certain studs and bolts.

In order to obtain a good view of a local cricket match at Hull on Saturday, THOMAS BUTLIN, aged 12, climbed an electric standard and was KILLED through touching the live wires. At the inquest on Monday it was stated that there was barbed wire round the pole about half-way up, but Butlin got past it. The boy did not know he was trespassing, as there was no notice board on the gate. The Deputy Coroner (Dr. T. C. Jackson) said that the Corporation, acting upon instructions of the Board of Trade, had every fifth pole marked "Danger." A boy, Taylor, who was with Butlin at the time of the accident, and who had tried to prevent him from climbing the pole, said he noticed the next post to where the accident happened had "Danger" on it, and he pointed this out to his companion, who said: "This one will be all right." A verdict of "Accidental death" was recorded. Mr. Hopkins (for the Hull Corporation) said he would report the circumstances to the Electricity Committee, who would see whether anything could be done to prevent a similar accident in the future.

Obituary.

We regret to report the death on Sunday of MR. R. E. GRAVES, Chief Inspector of Factories.

The death occurred on May 10, at the age of 61, of MR. FREDERICK EDWARDS, electrical engineer, of 2, Brooke Street, Dumfries.

The death took place at Llangammarch on Wednesday, May 17th, of MR. JOHN TEMPLE, C.B., in his eighty-fourth year. Mr. Temple entered the telegraph service in 1852, and after serving in Leeds, Manchester, and London, working on the staff of Sir Charles Bright, engineer-in-chief, obtained a post on the "Agamemnon" during the laying of the first cable across the Atlantic. After acting for three or four years as engineer for the Malta and Alexandria Cable and other cable companies he returned to England, and in 1865–6 assisted in laying the second Atlantic cable.

The death is announced of the distinguished American metallurgist, PROF. HENRY MARION HOWE, University of Harvard; and Professor Emeritus of the Columbia College, New York. Among his many contributions to the science of metallurgy was his great work on "The Metallurgy of Steel," published in 1891. He was also the author of innumerable papers on metallurgical subjects. In 1895 he received the Bessemer gold medal of the Iron and Steel Institute, and the Elliot Cresson gold medal of the Franklin Institute of Philadelphia; also a special prize and gold medal from the Société d'Encouragement pour l'Industrie Nationale, and, finally, in 1917, the John Fritz gold medal, an honour he shared with Lord Kelvin, who received it in 1905, Sir William White in 1911, and Sir Robert Hadfield last year.

Catalogues, Price Lists, &c.

The "GENII P.S." (push system) WATER HEATERS are illustrated and described in Leaflet Y 204 just issued by the manufacturers, George Nobbs, Ltd.

BRITISH INSULATED AND HELSBY CABLES, LTD., have sent us a copy of Pamphlet P.174, which they have just published, giving a list of cables supplied by them for working pressures of 11 000 V and over. This shows that 1 370¼ miles have been supplied at a voltage between 11 000 and 12 000 V, 114 at 13 000 V, 495 at 20 000 and 22 000 V, 17½ at 25 000 V, 39¼ at 33 000 V, 12 at 100 000 V.

Eight new leaflets have just come to hand from the EDISON SWAN ELECTRIC COMPANY, and deal respectively with moving coil switchboard type instruments (IN 252/5 and IN 252/6), portable combined testing set (IN 252/40), moving iron switchboard type instruments (IN 252/106), moving iron instruments for direct or alternating currents (IN 252/105), galvanometers (IN 252/79), moving coil type cell testers (IN 252/77), and insulation testing set (IN 252/73).

We have received from the ENFIELD EDISWAN CABLE WORKS a most useful wall calendar, which will carry us through to the end of next March. Beneath a photograph, showing the "Quest" (fitted with Enfield cables) in the Thames before starting for the Antarctic, are monthly tear-off slips of the same dimensions. The figures are printed in large black type, and below the calendar for the current month that for the preceding and following month is also given.

Arrangements for the Week.

FRIDAY, MAY 26th (to-day).

PHYSICAL SOCIETY OF LONDON.

5 *p.m.* At the Imperial College of Science, South Kensington, London. Lecture on "Atomic Weights and Isotropes," by Dr. F. W. Aston, F.R.S.

WOMEN'S ENGINEERING SOCIETY.

7 *p.m.* At 26, George Street, Hanover Square, London. Paper on "Wireless Telegraphy," by Mr. H. R. Rivers-More, B.Sc.

JUNIOR INSTITUTION OF ENGINEERS.

8 *p.m.* At Caxton Hall, London, S.W. "Engineering Appointments and How to Get Them," by Mr. J. Cameron Rennie.

ROYAL INSTITUTION OF GREAT BRITAIN.

9 *p.m.* At 21, Albemarle Street, London, W.1. "The Internal Combustion Engine: Its Influence and Its Problems," by Mr. W. E. Dalby, B.Sc., F.R.S.

TUESDAY, MAY 30th.

INSTITUTION OF ELECTRICAL ENGINEERS (SUMMER MEETING).

10 *a.m.* At the Royal Technical College, Montrose Street, Glasgow. Paper on "The Dalmarnock Generating Station," by Mr. R. B. Mitchell.

WEDNESDAY, MAY 31st.

INSTITUTION OF ELECTRICAL ENGINEERS (SUMMER MEETING), 10.15 *a.m.* At the University, Glasgow. Paper on "The Hydro-Electric Resources of the Scottish Highlands." by Prof. Magnus MacLean.

THURSDAY, JUNE 1st.

THE JUNIOR INSTITUTION OF ENGINEERS.

7.30 *p.m.* At the Institution of Electrical Engineers, Victoria Embankment, London, W.C.2. Gustave Canet Lecture on "The Railway Act, 1921," by the Rt. Hon. Sir Eric Geddes, G.C.B., G.B.E.

Companies' Meetings, Reports, etc.

Indian Electric Supply and Traction.

In the course of his speech at the annual meeting of the Indian Electric Supply and Traction Co., on Monday, Mr. John G. B. Stone, who presided, said that the company's earnings in Cawnpore showed steady expansion, but in remitting to this country the directors had had to contend with the fall in the exchange value of the rupee from 1s. 11¾d. to 1s. 4d. Owing, however, to their conservative policy in the distribution of profits in the past the directors were still in a position to recommend the same dividend as last year—namely, 10 per cent.—and to add a reasonable figure to the reserves. In the past year the output had been increased from 4 334 724 units in 1920 to 5 204 324 in 1921. The earnings of the company in India were £26 416, as compared with £35 189 in 1920. The fall in exchange accounted for nearly £10 000. They had erected a new alternating current h.t. power station on the banks of the Ganges, which was at present equipped with 6 000 kW of plant. Unfortunately, owing to unforeseen delays in delivery and erection of plant, the company had not yet had the benefit of its output, but the station was expected to be in working in August, if not earlier. As soon as the new station was open they would secure a large addition to their earnings, and so rapidly had the demand, actual and prospective, increased that in order to meet it they had found it essential to make arrangements for a further large extension to the new power station, for which purpose debentures had been issued to the extent of some £250 000, including the conversion and repayment of the existing outstanding £49 600 debentures. In order to get a closer and more accurate view of the company's business in Cawnpore, he went there in the early part of this year. It was a very active centre of trade, and in order to provide for the growth of its industries, etc., it had been found necessary to lay out a large new area as an extension to the city. The work was being actively pressed forward, and he did not think it would be more than a year or two before there would be an active demand from this new area.

Hurst, Nelson & Co. announce an interim dividend of 1s. per share, free of tax, on the ordinary shares.

Brisbane Electric Tramways Investment Company announce a dividend of 4s. per share, tax free, on the ordinary shares for the half year, making 8 per cent. for the year, carrying forward £46 163 subject to corporation profits tax.

The directors of the British Electric Traction Company recommend, subject to audit, the payment of a dividend of 4½ per cent. on the ordinary stock for the year ended March 31 last, compared with 4 per cent. for the previous year.

The profit of La Plata Electric Tramways for 1921, after providing for debenture and other interest, was £2 720, making with £14 531 brought in £17 251. The sum of £10 000 has been placed to reserve, leaving £7 251 to be carried forward subject to corporation tax, if any.

Allotment letters in respect to the recent issue of £250 000 Calcutta Tramways 7 per cent. second mortgage debentures, which was largely over-subscribed, show that applicants for less than £400 have been passed over. Applicants for over £400 and up to £1,000 have only received £100, and larger applicants in like proportion.

The annual meeting of the Rhondda Tramways Company was held last Thursday, Mr. Harold T. Barnett (chairman) presiding. Out of the disposable balance, £5 000 has been transferred to the reserve and renewals account, £4 000 in payment of a 4 per cent. dividend on the preference shares, leaving £1 825 to be carried forward. The election of Mr. E. Morley to the board to fill the vacancy caused by the death of Mr. Schlesinger, chairman of the company, was confirmed.

The accounts of the Ramsgate & District Electric Supply Company for the year to December 31 last show gross profit of £8 033 compared with £5 356 for 1920. After providing for preference share dividend, interest on loans and income tax, and adding the amount brought forward from last year, £477, there remains a balance of £6 011. The directors recommend the payment of a dividend of 10 per cent., that £2 200 be placed to the reserve account, and £1 500 to reserve for depreciation, leaving a balance of £311 to be carried forward.

The report of Johnson and Phillips, Ltd., for 1921 shows profit (including claim for repayment of excess profits duty), after making provision for bad and doubtful debts, and after charging to revenue upwards of £16 000 for maintenance of buildings, plant, etc., of £42 737, plus £38 727 brought in. After deducting directors' remuneration, debenture interest, etc., £18 428 for income and corporation taxes, and £12 255 for depreciation on machinery, etc., £15 138 remains to be carried forward. In view of the present state of trade caused by the engineers' lock-out and the consequent falling off of business, the directors do not recommend payment of a dividend on this occasion.

The South Eastern and Chatham Railway Companies Managing Committee, the S.E.R. Co., and the L.C. & D.R. Co. give notice of intention to apply to the Minister of Transport for an Order under Sec. 1 (1) (*b*) and (*c*) of the Railways Electrical Power Act, 1903, to authorise the construction of a generating station at Angerstein Wharf, Charlton, and works and transmission lines necessary for conveying electric power to certain of their railways in North and Mid Kent, and to work such railways by electric power, etc. A meeting of the proprietors of the S.E. Railway Company is to be held on June 2 to consider this application, and to authorise an agreement with a construction company for the electrification of the suburban lines of the South-Eastern and Chatham Railway Companies.

The net revenue of the Birmingham District Power and Traction Company for the year ended December 31 last, from the tramways and from dividends and interest upon investments, was £99 830. After deducting payments to local authorities, income tax, etc., there is a surplus of £62 840, while £4 508 was brought forward, making a total of £67 348, from which had to be deducted interest on debenture stock, provision for renewals, dividend on the cumulative participating preference shares, and £9 430 placed to the debenture sinking fund, leaving a balance of £25 657. The directors recommend a dividend of 6 per cent. on the ordinary shares, carrying forward £2 981. The Shropshire, Worcestershire, and Staffordshire Electric Power Company was also affected by the trade depression, but there were signs of improvement in the industrial position.

The net profit of Babcock and Wilcox, Ltd., for the year to December 31, 1921, amounted to £490 181, to which was added the balance brought forward from the last account of £99 828, making £590 008 10s. From this sum had to be deducted interim dividends paid in November of 3 per cent. on the preference shares, 2½ per cent. on the second preference shares, and of 7 per cent. on the ordinary shares, amounting to £157 894, leaving a balance of £432 114, from which the directors recommend that the following dividends be paid for the half-year ending December 31 last: 3 per cent. on the preference shares (less income tax), £3 000; 2½ per cent. on the second preference shares (less tax), £4 476; 9 per cent. on the ordinary shares (tax free), £193 394 10s., making a total of £200 871. The sum of £150 000 is to be placed to reserve and £10 000 to the staff pension fund, leaving a balance to be carried forward of £71 243.

The report of Siemens Brothers and Co. for 1921 states that the company has not escaped from sharing in the general trade depression, though it had obtained its full share of orders in the market. Fortunately, contracts in hand from 1920 enabled the company's output to be maintained almost on the previous year's level, except in the case of submarine telegraph cable shops, where work became scanty in the latter months of the year. Prospects in this department are now better. Reduction in output of lamps from Dalston factory was necessary owing to the general depression also affecting the lamp trade and to dumping of Dutch lamps on the English market and colonies. Dumping has now been effectually stopped, so far as gas-filled lamps are concerned, by a recent judgment in the House of Lords upholding an important patent in which the company is interested controlling manufacture of such lamps in this country. No definite assessments have yet been made for liability to excess profits duty for 1918, 1919 and 1920, but £100 000 was paid during the year in respect of same. Profits for 1921 are not liable. The profit was £200 093, plus £437 218 brought in, making £638 212, less corporation tax for 1920 and 1921 £29 100. The directors recommend a final dividend of 1s. per share on the ordinary shares, making 10 per cent. for the year, free of tax, to write off book value of s.s. "Faraday" £10 000, carrying forward (subject to balance of excess profits duty for 1918, 1919 and 1920) £334 112.

The report of the British Thomson-Houston Company for 1921 states that no new works were begun during 1921, and the amounts expended during the year were principally in connection with the completion of the extensions at Rugby, and with the glass works being erected at Chesterfield. It is expected that the latter will be completed during the current year. The profits for the year, after deducting all expenses and charges other than interest on debentures and loans, were £509 259, plus £225 892 brought in, making £735 150, less interest on debentures and loans, £119 446, leaving £615 704. Of this amount the directors recommend that £160 000 be placed to depreciations, reserves, etc., and the payment of dividends at 7 per cent. free of income tax on the preference shares, and 6 per cent., tax free, on the ordinary shares, leaving £230 704 to be carried forward. Arrangements on reasonable terms are practically completed with the holders of the preference shares, whereby from January 1, 1922, the dividends thereon will be at the rate of 7 per cent. per annum, subject to income tax. During the year, the directors arranged for the issue of £1 500 000 par value 7 per cent. mortgage debenture stock, being part of an authorised issue of £3 000 000. The issue was largely over-subscribed. From the proceeds the company's indebtedness was substantially reduced, and since December 31 the entire amount due to the International General Electric Company has been paid off. Debenture stock outstanding amounts to £146 995. The amount outstanding at December 31, 1921, was £152,295. Since the beginning of the year, £7 500 par value of the new 7 per cent. debenture stock has also been retired.

New Companies.

Hamilton and Co.

HAMILTON AND CO., LTD. (18 222). Private company. Reg. in Edinburgh, May 18. Capital, £2 000 in £1 shares. Electrical, consulting and general engineers, etc. Subscribers: A. G. Hamilton and A. R. Fyfe. Registered office: 135, Buchanan-street, Glasgow.

Calphos Electrical Company.

CALPHOS ELECTRICAL COMPANY, LTD. (181 726).—Private company. Reg. May 12. Capital, £100 in £1 shares. Dealers in electric and other lamps and fittings, &c. First directors: J. Pedersen and F. E. Kewley. Reg. office: 66, Victoria-street, London, S.W.

W. K. Simpson and Company.

W. K. SIMPSON AND CO., LTD. (181 674.) Private company. Reg. May 9. Capital, £2 000 in £1 shares. Manufacturers of and dealers in scientific instruments of all kinds, electrical apparatus, etc. First directors: W. K. Simpson, F. J. Milestone. Registered office: 38, Goddard Avenue, Hull.

Sadgrove & Company (Birmingham).

SADGROVE & COMPANY (BIRMINGHAM), LTD. (181 770).—Private company. Reg. May 13. Capital, £5 000 in £1 shares. Autogenous welders, mechanical, constructional, electrical engineers, &c. Subscribers: H. F. V. Sadgrove and H. J. Ardley. Secretary: H. G. Sadgrove. Reg. office: 140, Conybere-street, Birmingham.

Good Bros.

GOOD BROS., LTD. (181 852). Private company. Reg. May 18. Capital, £3 000 in £1 shares (2 900 cumulative preference and 100 ordinary). Manufacturers of and dealers in electrical, magnetic, telegraphic, telephonic and other appliances, etc. Permanent directors: S. Coxon, W. Inglis and F. M. Soulsby. Registered office: 35, South John-street, Liverpool.

Triumph Electric Manufacturing Company.

TRIUMPH ELECTRIC MANUFACTURING COMPANY, LTD. (181 843).—Private company. Reg. May 17. Capital, £6 000 in £1 shares. To acquire the business carried on by A. T. Costigan and C. E. Jenks, trading as "The Triumph Electric Company," at 16, Loveday-street, Birmingham. Permanent directors: A. T. Costigan, C. E. Jenks and W. L. Topple. Registered office: 16, Loveday-street, Birmingham.

Woodcliff.

WOODCLIFF, LTD. (181 910).—Private company. Reg. May 19. Capital, £2 000 in £1 shares. Manufacturers and sellers of all electrical and mechanical processes or appliances for treating silver or other metals, etc., and to adopt an agreement with R. F. Woodburn. First directors: R. F. Woodburn (managing director), W. Ratcliff and H. R. Wilson. Secretary: H. R. Wilson. Registered office: 33, Southwick-street, Paddington, W.2.

T. C. Murphy & Company.

T. C. MURPHY & COMPANY, LTD. (181 771).—Private company. Reg. May 13. Capital, £3 000 in £1 shares (500 preference and 2 500 ordinary). To adopt an agreement with Ada A. Murphy, and to carry on the business of manufacturers of and dealers in ebonite, vulcanites, rubber goods, and other insulating materials. First directors: G. H. Almenrader and Mrs. A. A. Murphy. Registered office: 10, Manchester-avenue, Aldersgate-street, E.C.1.

John Fowler and Co. (India).

JOHN FOWLER AND CO. (INDIA), LTD. (181 834). Private company. Reg. May 17. Capital, £1 000 in £1 shares. To acquire the branch business carried on by John Fowler and Co. (Leeds), Ltd., in India, and to carry on the business of civil, hydraulic, telegraph, mechanical and general engineers, manufacturers of and dealers in wire and other cables, etc. First directors: A. Fowler, C. H. Fowler, E. G. Pelly and T. Davis. Reg. office: 113, Cannon-street, E.C.

H. Cecil Taylor.

H. CECIL TAYLOR, LTD. (181 779). Private company. Reg. May 15. Capital, £2 000 in £1 shares. To acquire the business of an advertising agent and consultant carried on by H. Cecil Taylor at 15-16, Steelhouse-lane, Birmingham, and to carry on the same and the business of electricians, manufacturers of and dealers in mechanical devices and illuminated and other signs for advertising, etc. First directors: H. C. Taylor, I. Mindelsohn and J. W. Pickavant. Registered office: 6, Grosvenor-buildings, Steelhouse-lane, Birmingham.

Gas and Electricity Development Company.

GAS AND ELECTRICITY DEVELOPMENT COMPANY, LTD. Registered May 9. Private company. Nominal capital, £2 000 in £1 shares. To adopt an agreement with Sir Charles Bright and Partners, Ltd., The Premier Gas Engine Co., Ltd., Crompton and Co., Ltd., and F. J. Palmar, and to carry on the business of gas, electricity and water supply, etc., engineers, electricity and gas makers and distributors, consultants, technical and financial advisers, and heat, light and power specialists, etc. Signatories to the Memorandum of Association: E. W. Goodale and R. W. Fiddes. Registered office: 146, Bishopsgate, E.C.2. The file number is 181 648.

Tenders Invited and Accepted.

UNITED KINGDOM.

SHEFFIELD ELECTRICITY DEPARTMENT. May 30.—Supply of materials and works required in connection with the erection and completion of a transformer sub-station in Standon Road, Wincobank; also of a small pump house at Blackburn Meadows power station, Sheffield. Particulars from Mr. S. E. Fedden, General Manager and Engineer, Commercial Street, Sheffield.

ISLINGTON (LONDON) BOROUGH COUNCIL, June 1.—Renting of electric light standards for affixing electric advertisement signs. Forms of tender, etc., from the Electrical Engineer, 50, Eden-grove, Holloway, N.7.

BARNES ELECTRICITY DEPARTMENT, June 5.—Supply, laying and jointing of about 3,500 yds. of triple concentric l.t cable. Particulars from Mr. C. S. Davidson, Electricity Works, High Street, Mortlake, S.W.

RHONDDA URBAN COUNCIL, June 6.—Two sets of switchgear for sub-stations. Specification, etc., from the Engineer, Electricity Works, Porth, Glam.

Y.M.C.A., OLD COLWYN, June 7.—Lighting scheme. Particulars from Mr. J. Evans, Architect, Mohrcroft, Old Colwyn.

MANCHESTER ELECTRICITY COMMITTEE, June 13.—Specification No. B.32, electrical distance indicating and recording thermometers; 5 electrically driven fans (B.33); 6 electrically driven auxiliary circulating water pumps (B.34); electric capstans and bollards (B. 35). Particulars from Mr. S. L. Pearce, chief engineer and manager, Dickinson Street, Manchester.

SALFORD ELECTRICITY DEPARTMENT, June 15.—Supply and erection of turbo-generators (specification A.P.S.1); boilers, stokers, etc. (specification A.P.S.2). Particulars from the Borough Electrical Engineer, Electricity Station, Frederick Road, Salford.

AUSTRALIA.

THE VICTORIAN STATE ELECTRICITY COMMISSIONERS, September 1.*—Supply and delivery of (1) feed water heaters and vapour condensers (specification No. 226); (2) feed water evaporators (specification No. 227).

VICTORIAN ELECTRICITY COMMISSION, June 17.—Aluminium steel-cored cable and accessories. Specification (No. 243) from the Agent General for Victoria, Melbourne-place, Strand, London, W.C.2.

WELLINGTON CITY CORPORATION, June 10.—Supply and delivery, c.i.f., of one 25-ton overhead travelling crane (Sec. "C"); three 1 500 kW rotary converters with transformers, and one 500 kW rotary converter with transformer (Sec. "D"). Particulars from Preece, Cardew and Rider, 8, Queen Anne's-gate, Westminster, S.W.1.

BULGARIA.

BULGARIAN POST AND TELEGRAPH AUTHORITIES. June 15.* Supply of: (1) 1 A fuses, (2) cartridge fuses for protection from lightning, (3) 3 A fuses, (4) line annunciators, (5) carbon lightning arresters.

ITALY.

ITALIAN STATE RAILWAYS. July 31.—The limit of the period for the reception of tenders for the electrification of the Bologna-Venice-Monfalcone line, fixed previously for April 30 last, has been postponed until July 31, 1922. Offers received before April 30 will be returned in order that they may be re-presented before July 31.

The EDISON SWAN ELECTRIC CO. have secured from the War Office a contract for the supply of dry batteries.

BIDEFORD AND DISTRICT ELECTRIC SUPPLY CO. has accepted the tender of Crompton and Co. for the erection and equipment of an electricity generating station, &c.

CHIPPENHAM Town Council has accepted the tender of the Electric Supply Co. for electricity for public lighting for six months at 6½d. per unit and £1 7s. per quarter for maintenance.

A Reuter's message states that the GOVERNMENT OF NEW ZEALAND has accepted further tenders aggregating £32 000 in connection with hydro-electrical installations on the Waikato River, Auckland Province. The acceptances comprise tenders for head gates, turbines, generators, and exciters. All the tenders accepted were British, including one Canadian, although in some cases foreign tenders were the lowest.

LONDON County Council have accepted the following tenders for works at the new County Hall: Express Lift Company, eight electric service lifts (extension of existing sub-contract), £3 470; Stella Conduit Company, steel conduits and accessories, £2 889 2s., further quantities, not exceeding £4 000, and c.i. boxes, £263 14s. 6d., further quantities not exceeding £600; Dorman & Smith, main switchboard for auxiliary lighting supply, £800; Crompton & Company, motor-booster for auxiliary lighting supply, £850; P. W. Rands, electric fittings (about 600), £950; Davis, Cash & Company, ditto (about 960), £1 170; Best & Lloyd, ditto (about 750), £600; Dorman & Smith, cut-outs for permanent installation, £230; Hooper's Telegraph & Indiarubber Works, Ltd., twin flexible conductors, £150; Sterling Telephone & Electric Company, about 70 division bells, £450; Lamson Pneumatic Tube Company, pneumatic despatch tube in connection with electric annunciators, £100.

SYDNEY (N.S.W.) Corporation have accepted the tender of the Electricity Meter Manufacturing Co., for 5A meters, £3 187.

MOUNTAIN ASH Urban Council have accepted the tender of W. T Henley's Telegraph Works Co. for e.h.t. overhead and underground transmission mains. Five tenders were received.

MELBOURNE (Victoria) Electricity Supply Committee have accepted the tender of British Insulated and Helsby Cables, Ltd., for copper bars, £153, and 25 tons bare h.d. copper cable, £3 267.

GLASGOW Corporation have accepted the following tenders: Metropolitan-Vickers Electrical Co., h.p. switchgear for Whitevale sub-station; Electro-Mechanical Brake Co., spare resistance for electric welding plant; J. Spencer, Ltd., steam piping for 10 000 kW turbo-alternator; Stewarts and Lloyds, Ltd., tramway poles.

HAMMERSMITH Borough Council have accepted the tender of the Hackbridge Cable Company for 1 000 yards 0·05 l.t. cable at £163 10s., 500 yards 0·2 l.t. cable at £183 5s., and 500 yards $\frac{7}{16}$ twin cable at £43 10s.; also the tender of Ferranti, Ltd., for the supply of ordinary and pre-payment meters for 12 months commencing April 1, 1922.

HESTON AND ISLEWORTH Urban Council have been recommended to accept the following tenders: Pirelli General Cable Works (lowest tender), 3 500 yards 0·75 sq. in. single core, paper insulated, lead covered cable, for 600 volts, £1 720, and with 15 lead sleeves and connectors for same, £5 6s. 3d. (Seven tenders received, highest £1 925 and £20 for cable and sleeves respectively); G. Warne (lowest tender), 1 500 yards rectangular troughs and covers, 5 in. by $2\frac{3}{4}$ in., 1s. $4\frac{1}{2}$d. per yard (six tenders received, highest 4s. $1\frac{1}{2}$d.); British Insulated and Helsby Cables, Ltd. (lowest tender), two 4-way link disconnecting boxes (five tenders received, highest £82 5s.), with frame and cover, £45 11s.; General Electric Co., £187 (one other tender received, £200), 1 000 ampere feeder panel, with circuit breakers, instruments and switches.

Winding-up Petition.

CORONA LAMP WORKS, LTD. A petition for winding-up has been presented by the British Thomson-Houston Co., Ltd., and is to be heard before the Royal Courts of Justice, Strand, June 13, 1922.

Bankruptcy Information.

COUPE, George Francis, 2, Spring-gardens, Stockport, electrical engineer. Receiving order, May 13. Debtor's petition. First meeting, May 31, at 3.30 p.m., Official Receiver's Offices, Byrom-street, Manchester. Public examination, June 13, at 10.30 a.m., Court House, Vernon-street, Stockport.

FRANCIS, William, 4, Prospect Place, Cheam, Surrey, electrical engineer. Receiving order, May 16. Creditor's petition. First meeting, May 30, 12.30 p.m., 29, Russell Square, W.C.1. Public examination, June 21, 11 a.m., County Court, Scarbrook Road, Croydon.

MAGSON, Reginald Silver, 10, Stoney Stanton-road, Coventry, as R. S. MAGSON AND CO., electrical engineer. First meeting, May 31, at 3 p.m. Official Receiver's Office, The Barracks, Smithford-street, Coventry. Public examination, June 12, 2.45 p.m., County Hall, Coventry.

MORGAN, Edward William, Eccles Mill, Monton-lane, Eccles, Lancashire, electrical engineer, etc. Receiving order, May 17. Creditor's petition.

Notice of Dividend.

MATHERS, Ernest Edward, 10c, High Street, Doncaster, electrical engineer. Amount per £, 11$\frac{3}{4}$d. First and final. Payable, May 24, 14, Figtree Lane, Sheffield.

Order made on Application for Discharge.

KERSHAW, Arthur, and WOOD, Charles Herbert, in partnership as electrical engineers and merchants, 9, Bradford Road, Dewsbury, under the style of KERSHAW & WOOD. Order made April 5. Discharged subject to consenting to judgment for £200 and costs of judgment.

Partnership Dissolved.

GREEN, Frederick Samuel, CAIG, John David, and CAIG, Archibald, electrical engineers, 61, Renshaw-street, Liverpool, under the style of CAIG BROS. AND JONES, by mutual consent as from April 27, 1922. Debts received and paid by J. D., and A. Caig, who will continue the business.

WALKER, Harold Stephen, PARTRIDGE, John Alfred, and MAYER, Frank Antony, carrying on business for the manufacture, sale and exchange of electrical and wireless instruments and material, 22, Park Road, Colliers Wood, Merton, S.W. 19 under the style of THE WIRELESS EQUIPMENT COMPANY, by mutual consent as from May 8, 1922. Debts received and paid by H. S. Walker and J. A. Partridge.

Edinburgh Gazette.

BROWN (J. L.) AND CO., electrical engineers, 920, Pollokshaws Road, Glasgow. In this sequestration A. P. Gilmour, 174, West George Street, Glasgow, has been elected trustee. Examination of the Bankrupt at 70, Hutcheson Street, Glasgow, Wednesday, May 24, at 10 a.m. Meeting of creditors within the chambers of Nelson, Gilmour and Co., 174, West George Street, Glasgow, Tuesday, June 27, 1922, at 3 p.m. Particulars of claims to the trustee by June 5.

LIVINGSTONE AND MALCOLM, electricians, 7, Canal-street, Coatbridge. In this sequestration William Gilchrist, chartered accountant, Glasgow, has been elected trustee. Examination of the bankrupts in the Sheriff Court House at Airdrie, on Tuesday, May 30, at 10.15 a.m. Creditors' meeting at the trustee's chambers, 30, George-square, Glasgow, on Thursday, June 8, at 11 a.m.

Bankruptcy Proceedings.

GIBBONS, Albert Ralph, 8, The Parade, New Eltham, Kent-electrical engineer. The statement of affairs shows liabilities of £587 and no assets. Debtor attributes his failure to depression in trade, depreciation of stock, losses on contracts and unremunerative wages paid. For eight years prior to 1914 he carried on business as a electrician and automobile engineer at Tunbridge Wells. In March, 1919, he started business at his present address as an electrical and antomobile engineer with £90 capital. The business was successful until about March, 1921, when there was a depression in trade, and he was under the necessity of retaining a number of skilled workmen for whom he had not full remunerative employment. Since September, 1921, the creditors had pressed for payment, and in December, 1921, a creditor obtained judgment for £145. The only books of account kept were a creditors' ledger and cash book. At the first meeting of creditors the matter was left in the hands of the Official Receiver, as trustee of the estate.

MAGSON, Reginald Silver, trading as R. S. MAGSON AND CO., 10, Stoney Stanton-road, Coventry, electrical engineer. The receiving order in this matter was made in May 11 on debtor's own petition. The statement of affairs shows liabilities of £496, while the assets are estimated to realise £283, or a deficiency of £213. Debtor attributes his failure to illness of self and family. He commenced business in March, 1912, at his present address as an electrical engineer, his capital consisting of £20 cash saved. Shortly afterwards he borrowed £40 as additional capital, which had since been repaid. He became aware of his position about four months ago.

RIDGWAY, Fred, and TYNAN, Thomas, trading as RIDGWAY AND TYNAN, 21, Bowling Old-lane, Bradford, electrical engineers. Statement of affairs shows gross liabilities of £439, of which £432 is expected to rank for dividend, against net assets of £79, or a deficiency of £353. At the first meeting of creditors the matter was left in the hands of the Official Receiver as trustee.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by Messrs. Mewburn, Ellis & Co., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

Complete Specifications.

171 717 Radio Communication Co., Ltd., and Taggart, J. Scott-. Apparatus for detecting or translating electrical impulses. (20/5/20).
171 716 Ledwinka, J. Jigs for use in electrically welding the parts of automobile bodies. (20/5/20).
145 469 Siemens-Schuckertwerke Ges. Electric driving of ship propellers. (1/8/16).
147 785 Apple, V. G. Dynamo-electric machines. (23/4/17).
149 217 Huth Ges., Dr. E. F., and Loewe, Dr. S. Process and connection for obtaining a strengthening of wireless messages. (11/6/17).
149 664 Ebner, A. Automatic stopping device for talking-machines of all kinds worked by electric motor. (12/7/20). (Convention date not granted).
171 412 Siemens-Schuckertwerke Ges. Synchronous motors for mechanical loads. (21/7/19).
171 743 Vesme, E. Apparatus for the production by electrolysis of gas under pressure. (26/7/20).
171 752 British Thomson-Houston Company, Ltd., Clinker, R. C., and Carter, F. W. Frequency filters. (16/8/20).
171 756 Prentice. H. B. Electric switches. (17/8/20).
150 323. Akt.-Ges. Brown, Boverie et Cie. Regulating resistances composed of contact-pressure elements with spring-pressing mechanism. (26/8/19).
171 782 Young, A. Machine for the generation of electric currents also applicable as a motor. (23/8/20). (Addition to 171 782).
171 795 Metropolitan-Vickers Electrical Company, Ltd. (Westinghouse Electric and Manufacturing Company). Electrical systems of automatic substations. (26/8/20).
171 796 Metropolitan-Vickers Electrical Company, Ltd. (Westinghouse Electric and Manufacturing Company). Automatic electrical sub-station systems. (26/8/20).
163 021 Wilson Welder and Metals Company Inc. Electric rheostats. (7/5/20).
171 808 Igranic Electric Company, Ltd. (Cutler Hammer Manufacturing Company). Electric motor controllers. (3/9/20).
171 809 Metropolitan-Vickers Electrical Company, Ltd. (Westinghouse Electric and Manufacturing Company). Polarized relay for use in controlling rotary converters. (3/9/20).
171 823 Coulson, W. T., and Optalyte, Ltd. Charging-boards for electrical batteries. (14/9/20).
171 829 Sphinx Manufacturing Company, Ltd., and Clark, W. A. Terminal protectors for sparking-plugs. (17/9/20).
171 836 British Thomson-Houston Company, Ltd. (General Electric Company). Electric transformers and the like. (20/9/20).
171 846 Waygood Otis, Ltd. (Otis Elevator Company). Motor control systems for electric lifts and the like. (23/9/20).
171 850 Lofts, G. H. Electric irons that are fitted with a power's-on indicator. (28/9/20).
171 857 British Thomson-Houston Company, Ltd. (General Electric Company). Operating-mechanism for searchlights, guns, and the like. (5/10/20).
171 859 Thompson, H. H., and Davies, A. E. Magnetic separators. (8/10/20).
152 361 Akt.-Ges. Brown, Boveri, et Cie. Process and apparatus for regulating the direct-current voltage in metal vapour rectifier installations. (14/10/19).
171 870 British Electric Plant Company, Ltd., and Whitesmith, I. N. Brush-holder for dynamo-electric machinery. (16/10/20).
171 878 Oldham, O., Oldham, G., and Oldham, J. Electric switches (21/10/20). (Cognate application, 19 097/21).
167 445 Pedersen, P. O. Arc generators for producing oscillating current of high frequency. (5/8/20).
165 433 Bergman, S. R. Electric reactors. (24/6/20).
171 900 Tessmann, H. F., and Horn, R. C. Insulation of electric overhead lines. (23/11/20).
171 904 British Thomson-Houston Company, Ltd. (General Electric Company). Electric motor control systems. (29/11/20).
171 906 Woodburn, R. F. Electric resistance welding. (1/12/20).
155 579 Metropolitan-Vickers Electrical Company, Ltd. Electrolytes for use in electrolytic cells. (9/12/19).
171 911 British Thomson-Houston Company, Ltd. (General Electric Company). Regulating-systems for electric circuits. (8/12/20).
155 833 Automatic Telephone Manufacturing Company, Ltd. Telephone systems. (27/12/19). (Patent of Addition not granted).
157 104 Behn (nee Eplinius), H. Electric resistances. (3/1/16).
171 921 Cattley, L de M. Accumulator plates. (10/1/21).
159 887 Liebreich, E. Process of electrolytically separating chromium. (8/3/20).
158 222 Automatic Telephone Manufacturing Company, Ltd. Automatic telephone systems. (28/1/20).

APPLICATIONS FOR PATENTS.

May 8, 1922.

12 885 A. E. W. Maseyk. Electrically controlled gear-box.
12 886 K. A. Homer. Electric welding of cast iron.
12 890 F. Wilde. Generators, motors, &c.
12 910 J. H. Wild. Electric motors.
12 914 M. Guthrie. Electric lamp reflectors.
12 927 M. W. W. Mackie. Plug and socket connections for electric circuits.
12 939 M. W. W. Mackie. Dynamos and motors.
12 945 Evershed & Vignoles & J. C. Needham. Telegraph apparatus.
12 949 B. T.-H. Co. (G.E. Co.). Sound reproducing machines.
12 959 C. A. W. Hultman. Setting arrangements for selectors in automatic telephone systems, &c. (28/5/21 Sweden.)
12 970 Felten & Guilleaume Carlswerk Akt. Ges. Pupinizing high frequency telephone lines. (7/5/21 Germany.)
12 971 Akt. Ges. Brown, Boveri et Cie. Multiple control apparatus for electric railways. (1/4/22 Switzerland.)
12 974 J. Houston. Locking device for electric lamps.
12 975 Deutsche Glimmlampen-Ges. & J. M. Schmierer. Glow lamps. (9/5/21 Germany).
12 977 M. A. Persson. Electric contact plug.
12 983 English Elec. Co. & W. O. Manning. Trollies for transport of seaplanes, &c.
12 985 A. Wehnelt. Oxide cathodes for discharge tubes. (6/5/21 Germany).

May 9, 1922.

13 007 T. F. Wall. Electric condensers, &c.
13 047 N. F. S. Hecht. Wireless systems.
13 048 N. F. S. Hecht. Thermionic valve circuits.
13 049 R. T. Smith. Regulating wind-driven electric generators on aircraft.
13 059 G. H. Armstrong. Electric switches.
13 067 D. W. Dant. Electric fittings.
13 079 Metropolitan-Vickers Electrical Co., R. Brooks & B. A. G. Churcher. Controllers for electrical apparatus.
13 080 Metropolitan-Vickers Electrical Co., R. Brooks & R G. Cunliffe Controllers for electric traction, &c.
13 081 Metropolitan-Vickers Electrical Co. & A. Priestly. Controllers for electrical apparatus.
13 082 Metropolitan-Vickers Electrical Co., R. Brooks & W. T. Gray. Controllers for electric traction, &c.
13 084 Naamlooze Vennootschap Philips Gloeilampenfabr. & D. Lely. Leading in conductors for vitreous material.
13 085 Naamlooze Vennootschap Philips Gloeilampenfabr. & J. C. Lokker & E. Oosterhuis. Leading in conductors for vitreous material.
13 095 J. H. Compton. Electrically operated organs.

May 10, 1922.

13 117 R. Greaves. Magnetic separators.
13 127 A. D. Clark & P. O. Knowles. Electric switch boxes, &c.
13 168 H. S. Potter, & M.L. Magneto Synd. Electric lamps for mines, &c.
13 169 Callender's Cable Co. & S. E. R. Beecroft. Electric cables.
13 187 H. Booth. Wireless telegraphy and telephony.
13 215 B. T.-H. Co. Electric relays. (5/7/21 U.S.)
13 218 Western Electric Co. Loaded signalling conductors.
13 229 P. Fogarty. Magneto control devices.

May 11, 1922.

13 254 A. Mayere. Arc lamps. (12/5/21) France.)
13 267 O. T. Baker. Exterior adjustable brush rocker for dynamos, &c.
13 278 A. E. Jones & S. Robison. Telephone, &c., call register.
13 298 F. Contelf. Current converting machinery.
13 307 P. H. Taylor. Magnetos.
13 310 A. H. Railing, A. E. Angold, H. C. Turner & P. H. Coales. Tripping gear for automatic circuit breakers.
13 316 F. Cicogna & E. Mariani. Press button switches for electric circuits.
13 322 British Electric Transformer Co. & J. Roothaan. Transformers.
13 330 F. Ainsley & W. Platt. Overhead electric tramway systems.
13 341 F. Crawford. Electric vehicles.
13 342 Western Electric Co. Loaded signalling conductors.
13 343 Naamlooze Vennootschap Philips' Gloeilampenfabr. Electric discharge tubes. (14/6/21 Holland).

May 12, 1922.

12 910 H. F. Basset. Electric motors.
13 382 E. Y. Robinson. Generation of alternating currents by thermionic devices.
13 384 R. W. Strawson. Electrode holder for electric welding.
13 394 J. Dugdill. Movable supports for electric lamps, &c.
13 412 C. R. Jarman. Exploding air bombs by electricity.
13 422 A. P. Strohmenger. Welding electrodes.
13 442 B. T.-H. Co. (G. E. Co.). Circuit controllers.
13 445 A. Rothschild. Wireless induction coil holders.
13 447 A. P. Ford. Portable accumulator cells.
13 450 P. Arnouil. Convertible and multiple electric junction plugs. (12/5/21 France).
13 454 Western Electric Co. Electron discharge devices.
13 460 O. & S. Oilless Bearing Co. & R. B. Wiggins. Checking apparatus for telephone calls.
13 465 Siemens-Schuckertwerke. Pressure applying means. (20/9/21 Germany.)
13 471 Etab. de Dion-Bouton, Soc. Anon. Regulation devices for electric installations. (27/6/21 France).

May 13, 1922.

13 506 Automatic Telephone Manufacturing Co. & C. Gillings. Telephone systems.
13 509 Vereinigte Metall. & Stanzwerke. Vapour lamps.
13 525 J. Dugdill. Movable supports for electric lamps, &c.
13 547 L. G. A. D. C. Gaunt. Electrical control of hydraulic machinery, &c.
13 551 W. P. Granville & W. S. Smith. Cables for submarine telegraphs and telephones.
13 552 Ges. fur Drahtlose Telegraphie. Wired wireless telephone systems. (14/5/21 Germany.)

Prices of Metals, Chemicals, etc.

Tuesday, May 23.

		Price.	Inc.	Dec.
Copper—				
Best Selected	per ton	£65 15 0	£2 5s.	—
Electro Wirebars	,,	£70 0 0	£2	—
H.C. Wire, basis	per lb.	0s. $10\frac{5}{16}$d.	$\frac{1}{4}$d.	—
Sheet	,,	0s. $9\frac{11}{16}$d.	$\frac{1}{4}$d.	—
Phosphor Bronze Wire (Telephone)—				
Phosphor Bronze Wire, basis	per lb.	1s. $2\frac{5}{16}$d.	$\frac{1}{4}$d.	—
Brass 60/40—

Aluminium Ingots	per ton	£100 0 0	—	—
Spelter	,,	£27 5 0	5s.	—
Mercury	per bottle	£12 10 0	£1 10s.	—

Sulphur (Flowers)—Ton £10 15s. *Sodium Chlorate*—Per lb. $3\frac{1}{4}$d.
,, (Roll-Brimstone)—per ton £10 15s. *Sulphuric Acid* (Pyrites, 108°) per ton, £9.
Sodium Bichromate.—Per lb. $5\frac{1}{4}$d. *Copper Sulphate*.—Per ton £26 10s.
Boric Acid (Crystals). Per ton £60.
Rubber.—Para fine, $10\frac{1}{2}$d.; plantation 1st latex, $7\frac{1}{2}$d.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd.

The Editorial, Advertisement and Publishing Offices of "The Electrician" are at 8, Bouverie Street, London, E.C. 4. Telegrams: Benbrotric, Fleet, London. Telephone: City 9852 (5 lines).

The subscription to "The Electrician" is £1 5 0 per annum in the United Kingdom and £1 10 0 per annum Abroad. Advertisement Rates can be obtained on application to the Manager. Advertisement copy and blocks should be received on the Friday preceding date of publication.

THE ELECTRICIAN

ESTABLISHED 1861.

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

Electrical Engineering, Industry, Science and Finance.

No. 2298. [Vol. LXXXVIII. No. 22.] FRIDAY, JUNE 2, 1922. Prepaid Subscription U.K., £1 5s. per ann.; Abroad, £1 10s. Price 6d.

CONTENTS.

Notes of the Week.

Wireless and the Wreck of the "Egypt."

At a time when "broadcasting" is shortly to be started in this country, and when pressure is being brought to bear on the authorities to allow further facilities for transmission, both by amateurs and others, the letter from Mr. Thomas Hesketh, managing engineer of the Folkestone Electricity Supply Co., which was published in last Friday's "Times," should be carefully studied. Mr. Hesketh is himself a wireless amateur. On the night when the unfortunate wreck of the "Egypt" occurred he heard two or three separate S.O.S. calls west of the Isle of Wight. Then the jambing of normal traffic prevented further distress calls being heard, until the Niton station in the Isle of Wight and a French station, probably Ushant, began to call on the other stations to keep silence, as they were listening for S.O.S. calls.

An Appeal Disregarded.

According to Mr. Hesketh this appeal was disregarded, at any rate for a time, and "one home station and several foreign stations continued commercial working, rendering the selective reception of this otherwise clearly receivable message almost impossible." Even after the North Foreland station had subsequently called for silence commercial working still continued, and Mr. Hesketh estimates that from 35 to 45 minutes were lost at a time when every second was of importance. In commenting on Mr. Hesketh's letter Mr. Godfrey Isaacs points out that the "Egypt's" signals and the calls from Ushant were picked up without difficulty by a number of vessels, and that as all commercial wireless operations between ship and coast stations in the Channel are worked on a wave length of 600 m. every S.O.S. signal would be heard in the Channel and answered promptly not only by Government stations, but also by ships within range.

Some Change in the Present System Necessary.

Taken together these two communications form a powerful argument for some change in the present system. Wireless telegraphy, as has been shown again and again, is one of the most efficient methods of saving life at sea, and anything that detracts from that efficiency should be drastically forbidden. Mr. Hesketh suggests that the land lines should be used for giving publicity to the fact that an S.O.S. call has been heard, but Mr. Isaacs points out, quite rightly, that in this particular case that would have been of no avail. A better method seems to us to be to allocate a special wave length for S.O.S. working and for all powerful land stations to be equipped with special apparatus for picking up this call. The Marconi Company already have in use an automatic alarm, and its employment might well be extended. Ships' stations might be required to listen in on that wave length from time to time, and transmission on it, except in cases of real emergency, should be forbidden. The fact that such signals are now sent out on the ordinary commercial wave length is a condemnation of the present system, while the whole episode is an argument against further extending facilities for transmission.

An Industrial Entente.

At the present time engineers will be the first to agree that any proposal for bringing about industrial harmony is worthy of the most careful examination. What is wanted is not only a mere settlement of the present dispute but some tool which shall strike down to the very basis of the relations between employers and employed and discover a bedrock upon which a firm superstructure can be built. Only in this way can our trade develop and our commercial property be ensured. How can this bedrock

be found? We think that a letter published in last Friday's "Times" and signed on behalf of the Industrial League and Council shows one of the most certain ways. The only hope of industrial peace, the signatories say, is an effective entente between employers and employed founded on a mutual recognition of the essentials of each other's position. That recognition, unfortunately, has been too often lacking in the past. They propose to make it more clear that a group of employers and a group of trade unionists should meet in more or less continuous session to formulate a policy of agreement in its general bearings, and especially to secure "team working and the requisite level of technical and productive efficiency."

The Matter in Figures.

PASSING from the general to the concrete, we note that in the same issue of "The Times" Sir CHARLES MACARA recommends that work should be resumed until the differences in the engineering dispute can be settled. This may be a hard saying for some on both sides, but it is axiomatic, as he adds, that "the position of our trade is such that we cannot tolerate these prolonged stoppages." Mr. G. S. FRANCIS, honorary secretary of the National Confederation of Foremen, Managers and Supervisory Associations, puts the matter into the figures, which engineers are supposed to understand better than anyone else. In 1919 we lost 34 000 000 working days through strikes and trade disputes, in 1920 over 27 000 000, in 1921 nearly 90 000 000, and already, in the first five months of 1922, we have lost 30 000 000. What need, then, we may ask, have we of any further witnesses? The Industrial League and Council suggestion should be adopted with the least possible delay. And at any conference that is called, and running through any suggestion that is adopted for the alleviation of this trouble must go the recognition that it is human difficulties that have to be solved and human failings and weaknesses that have to be dealt with.

The Rutenberg Concession.

CONSIDERABLE stir has been caused, especially in Parliamentary circles, by the granting of a concession to supply electricity in Palestine to a Russian, one Pinhas Rutenberg. This concession amounts to an almost complete monopoly, the sort of thing every capitalist dreams of and seldom achieves. If the details given by Sir W. JOYNSON HICKS in a letter published in Monday's "Times" are to be believed, M. RUTENBERG is to be allowed two years to raise £200 000 and, if he succeeds, he will then be given a monopoly to use the waters of the Jordan for a term of seventy years, subject only to the proviso that existing users may continue to use such water, but no more, as they do at present. Expropriation of land and buildings is allowed, and no one else may supply electricity or do any work to that end. Finally, as a sort of make-weight, valid pre-existing concessions may be annulled in favour of the Rutenberg Company.

Why were British Firms Excluded?

THIS, it will be agreed, is a little strong. The whole of a most important development in a country which the British taxpayer has to maintain is to be handed over to a foreigner. Now we are not bigoted in this matter of giving of contracts to foreign firms. Indeed, we have often pointed out that British firms have themselves to blame when work goes abroad after tenders have been fairly invited. But in this case we believe no public tenders were invited. The concession was simply granted without any British firms being permitted to compete, and this at a time when our industry is starving for want of foreign trade. It is a matter which deserves, and, we hope, will receive, the fullest investigation.

Tramway Passengers Rights.

AN important decision on the rights and duties of tramway undertakings and on the liability of employers for the acts of their servants was given by the House of Lords on Friday, and should be carefully studied by those who are engaged in the operation of transport services. The circumstances out of which the action arose were trivial, but an important principle has been vindicated. A passenger on a Glasgow Corporation tramcar tendered an indented penny in payment of his fare, but the conductor refused to accept it and demanded another coin. As the passenger refused to comply with this request an inspector was called and then a policeman was summoned, the result being that the passenger, in spite of having given his name and address, was taken to the police station and there charged with not paying his fare and with tendering a defaced coin. After ten minutes' detention he was allowed to go, on giving an undertaking to appear in court next day. At the police office on the following day the passenger was informed that the charge against him was foolish.

The Issue to be Tried.

Thereupon he commenced an action for false imprisonment against the Corporation, whose by-laws allow their servants to detain and give into custody a person evading payment of his fare, if his name and address are unknown. The Lord Ordinary allowed the case to go to trial, but on appeal the First Division of the Court of Session reversed this on the ground that the Corporation had not given authority for the arrest under the circumstances. On appeal the House of Lords have now unanimously reversed this decision and restored the judgment of the Lord Ordinary, holding that the tramway employees were acting within the scope of their agency and that the passenger was entitled to have the issues of facts tried. As the action has yet to be tried we refrain from comment, except to say that it is equitable to presume that uniformed officials are *prima facie* acting in the course of their employment and in pursuance of authority conferred on them.

The S.E. Lancashire Electricity District.

THE scheme for the South-East Lancashire Electricity District, recently approved by the Electricity Commissioners, has now been embodied in a draft Order and will form the subject of a further inquiry at Manchester on the 20th inst. The Order purports to constitute the electricity district and to establish the South-East Lancashire Electricity Advisory Board as set out in the schedule to the Order, which will come into force as soon as it has been approved by a resolution passed by each House of Parliament. Particulars of the area of the District and of the technical scheme have already appeared in THE ELECTRICIAN, and as these have undergone but slight modification, the only points of interest are the constitution, powers and duties of the Advisory Board.

Powers and Duties of Advisory Board.

This Board is to consist of 50 members, of whom 42 are to be appointed by the authorised undertakers in the District (35 by local authorities and 7 by companies); four will be jointly elected by those local authorities who are not

undertakers but in respect of whose area there is a Provisional Order or Special Act, two by the remaining local authorities, and two by railway companies in the District. A Board of 50 would appear to be too big and unwieldy to be very effective in action, but its limited powers and duties will probably be performed by the Engineering Advisory Committee, which is to be appointed by the Board soon after the final approval of the scheme. The Board are to take all steps "within their power" to secure the carrying into effect of the technical scheme; they are bound to submit to the Commissioners within two years proposals for the extension of electricity supply in districts outside the areas of authorised distributors where there is a reasonable prospect of such supply being remunerative; and the Board may make investigations and recommendations to its "constituent authorities" and to the Commissioners upon any matter connected with the improvement and development of supply in any part of the District. Each "constituent authority" is required to submit plans and estimates of extensions of plant and main transmission lines to the Board, who will then investigate the matter and make a recommendation thereon.

Delegation of Powers.

THE Board also have the right to enter and inspect generating stations and main transmission lines, to make recommendations as to running hours and charges for supplies and to require statistics of supply from constituent members. As the Board may delegate any of their duties to a committee it will be found in practice that all real authority will be exercised by the Engineering Advisory Committee. We believe this would be a good thing, for it would ensure efficiency and progress, which cannot be expected from a Board of 50 without technical or scientific training. Each undertaking which sells more than five per cent. of the total units sold by all the authorised undertakers in the District can nominate one member of the Engineers' Committee; those selling more than three and less than five per cent., two members jointly; those selling more than one and a half and less than three per cent. will have one, and those selling less than one and a half per cent. will also have one member. There is power to co-opt an electrical engineer of one of the railway companies, and in the not unlikely event of railway electrification in the District he would prove useful.

National Electric Traction.

IN an article which we publish on another page of this issue Mr. ROGER T. SMITH gives his impressions of the discussions at the electric traction meetings during the recent International Railway Congress in Rome. We are glad to find that he agrees with the opinion that we expressed a week or two ago, that the greatest good of these gatherings comes not from the formal meetings and discussions, but from the informal interchange of ideas and experiences by "men engaged in the sale of transport in other countries where conditions are quite different from our own." We especially commend the phrase "sale of transport" to the attention of our readers. For to sell transport economically and profitably must be the aim of every railway company in this country, and the discovery of ways and means by which electric traction can do this is the real problem at the present time. It is a problem, therefore, which includes many other things beyond the mere choice of system, and upon some of these, as a result of his visit to Rome, Mr. ROGER SMITH, throws a useful light.

Methods of Generation and System.

A particularly interesting point is the influence of the methods of generation on the choice of system adopted. Mr. SMITH puts forward the suggestion that the single phase system has been adopted in countries where water power is abundant because the employment of that form of power makes it possible to use different plant for the generation of low frequency traction energy and the generation of high frequency energy for industrial and domestic purposes. That choice of frequency is indeed one of the most vital problems with which the railway electrical engineer has to deal, and it is interesting to note in passing that in Switzerland the frequency is being raised from 15 to $16\frac{2}{3}$ and that a definite distinction between the generation of the two forms of energy is being made.

The Limitations of Steam Generation.

Unfortunately such a separation of supplies is impossible in this country. For, as Mr. ROGER SMITH points out, as it is more economical for us to use large steam turbo-alternators and to generate at a high frequency, it almost follows as a corollary that we must use direct current traction in order that the same plant shall be employable for all electrical purposes. In other words, definite sets cannot be allocated to the traction and the industrial loads respectively, as is possible where water power is available. Though we do not suppose for a moment that this argument is incontrovertible by single-phase enthusiasts, it is one of the soundest reasons for the findings of the recent Advisory Committee on Electric Traction that we have yet seen advanced.

Direct Current on the Continent.

It is for this reason, and for the reason that transmission limitations, make it advisable that all generating stations should be "combined" stations, that has led Holland and Belgium to adopt direct current; and the same may be said for France, though this has not been the only factor in their choice. Unfortunately, the policy of most British railway companies that are considering the adoption of electric traction at the present time is in favour of a separate traction station. Arguments to support this policy may be found in dense traffic areas such as the London suburbs, but nothing can be said in favour of separate traction stations elsewhere. To obtain true economy there must be combined stations, and we hope therefore that for the general good individualism on this matter will give way to co-operation.

Some Important Technical Questions.

A word or two must also be said about the technical questions raised at the conference. As regards locomotive types, Mr. GIBBS objected to motors geared direct to the axles except for slow speeds, and thought that even though the quill drive was better it was not altogether satisfactory for heavy service. He preferred gearless motors, with the rod drive, especially on the counts of flexibility and weight distribution. This point does not seem to have been very much considered, though we believe that in this country and on the Continent opinion is rather against Mr. GIBBS.

The Overhead Equipment.

More information was available on the design and construction of the overhead equipment. We were glad to see

Mr. SAYERS insisting on the need for flexibility and the elimination of hard spots by increasing the number of points of suspension. Signor DONATI (an Italian engineer), who also insisted on the need for flexibility, was able to put forward an excellent argument in favour of simplicity by saying that only 80 minutes per month as compared with the 2 080 minutes due to other reasons were caused by the failure of the overhead equipment on the Italian State Railway. But even this might be reduced. The elimination of hard spots, as pointed out by Sir PHILIP DAWSON and the American and Swedish delegates, also has an important influence on the ease of current collection and trolley wire wear. No similar information on the effect on the wear of the contact rail of the method of mounting and fixing seems to have been given. Faulty insulators are not the least important of the troubles that arise in both cases.

Inductive Interference.

A good deal of information on the subject of inductive interference and its prevention was put forward. In Switzerland considerable alterations in the telegraph and telephone lines have been necessary, and in many cases they have been put underground. On the other hand, in France it was stated that it had been found quite possible to suppress all inductive interference without moving the lines, though the cost of the necessary apparatus was considerable. In Italy the heroic course has been taken of removing the telephone lines altogether. There was some difference of opinion as to the effect of direct current traction on telephone and telegraph lines, and this is generally a subject to which railway engineers in this country will have to give close attention. The final conclusion reached at Rome was that while it is technically possible to neutralise inductive effects it is not always financially sound to do so.

It is hardly to be expected that agreement would be reached on all the points discussed. Indeed, in the present state of our knowledge, it is not desirable that there should be agreement. But one thing appears perfectly clear. In its broadest aspect electric traction is rather a national than an international problem, and it is essential therefore that in every way our policy, design and equipment should be as thoroughly British as are the difficulties that have to be solved.

The Electricity (Supply) Bill.

THE threatened challenge to the Second Reading of the Electricity (Supply) Bill made by Mr. GEORGE BALFOUR was met by a promise of further concessions in Committee; a division was thus obviated, but the progress of the measure was delayed by nine days, and this may have an important effect on its ultimate fate. On the whole the debate was of very poor quality. Most of the speeches dealt with the history of the 1919 Act or with points which were more appropriate to the Committee stage. The efforts of Mr. BALFOUR and Mr. MARRIOTT were frankly directed to the advocacy of private enterprise and to the creation of a bogey to frighten the House about an extension of municipal trading. We must, however, recognise facts, and so must they. It is impossible to ignore the strongly entrenched position of municipal electricity supply, and therefore the provisions of the Bill are essential if any progress is to be made, as it must be made.

Fantastic Figures.

SOME fantastic figures of the expenditure of joint electricity authorities were given by Mr. MARRIOTT, who, on the authority of an anonymous financial critic, put the total amount to be borrowed at £110 000 000. His methods of calculation are so ingenious, not to say ingenuous, that they deserve to be put on record. The Electricity Commissioners having provisionally determined sixteen electricity districts, he assumes there will be more to follow, and so he takes 25 as the probable ultimate number. Then, as the authorised capital expenditure of all the electricity undertakings in the country at the end of 1918 was over £48 000 000, he assumes this figure to have risen to £60 000 000 by now. He puts this forward as the sum which will have to be borrowed by the Joint Electricity Authorities at the outset, and as each authority is allowed £2 000 000 for a new capital station and transmission lines, he makes the total £110 000 000! We believe that history has hitherto been Mr. MARRIOTT's *forte*, but, as he has evidently a vivid imagination, he should do much better in fiction.

Calculated to Scare.

No doubt the sum mentioned by Mr. MARRIOTT has been well calculated to scare timid ratepayers, who have been blistered by high rates and are alarmed at Poplar methods of finance. On analysis it will be seen, however, that there is no foundation for the figures. In the first place, he has no right to assume that Joint Authorities will be established in all electricity districts; probably we should not be far out if we put the total number at 10 or 12. In the next place, he has taken the *gross* capital authorised to be borrowed by the whole of the municipal authorities of the United Kingdom, whether in electricity districts or not. Now, a considerable proportion of the borrowed money has already been repaid by sinking funds or other means, and a further large sum must have been expended on the distributing networks of the undertakers and on plant and apparatus which will not be acquired by the Joint Authorities. When all proper adjustments of accounts are made we should be surprised if the total came to 50 per cent. of Mr. MARRIOTT's figure, and of that the London District will account for a large proportion. Further, whatever sums will have to be paid by Joint Authorities for the acquired generating plant and transmission lines will be paid to local authorities, who will then repay their existing loans, and so the total municipal debt of the country will not be increased by the transaction.

The Control of Joint Authorities.

THERE was also a great deal of unnecessary talk about the financial control of Joint Authorities and of the need of further safeguards. It must be remembered that the Electricity Commissioners only grant borrowing powers for sound schemes and that the periods allowed for the repayment of loans are well within the economic life of the plant, mains and other apparatus for which the money is borrowed. Further, the Joint Authorities must furnish annual accounts to the Commissioners, who have also the right to appoint auditors. We think, however, that the power to suspend the sinking fund for five or six years and to pay interest out of capital on unremunerative undertakings is one which should be sparingly used, and should only be authorised in exceptional circumstances and for strictly limited periods. We hope that this unedifying spectacle will soon be closed as the result of the passing of the Bill.

But as the session is already well advanced no time should be lost in bringing this about.

Conflicting Wisdoms.

DURING the recent debate on the Second Reading of the Electricity Supply Bill in the House of Commons, Sir PHILIP DAWSON, following Mr. GEORGE BALFOUR'S lead, wished to substitute the "wisdom" of the House for the "wisdom" of the Electricity Commissioners. In doing so Sir PHILIP DAWSON, referring to the Commissioners, naively asked, "Are they absolutely certain never to make a mistake?" fearing apparently that there was some little danger that they might "look at the picture a little too much from the rosy side." Now anyone who has followed the cogitations of the House on electricity supply legislation will not have anything like absolute confidence in the wisdom of the House. We can hardly imagine, for instance, anyone seriously claiming that the "wisdom" displayed by the House is greater than the "wisdom" displayed by the Commissioners, and when individual lay-members of the House dissertate on electrical questions wisdom of any sort is generally conspicuous by its absence. We notice, for instance, that a recent issue of the "Financial Times" contained an article by Mr. F. A. MACQUISTEN, M.P., on the Electrification of Railways in which he claims that "concurrently with electrification of the railway systems each railway company should be empowered to sell current for heating, light and power to the whole district wherein it operates," and cheerfully concludes by saying, "Let us therefore defeat the Electricity Bill, which will exclude the railways from what is their own by nature and circumstance." Now Mr. MACQUISTEN is a solicitor, and, we presume, fully acquainted with the whole system of electric lighting legislation, but here, at a single blow, he proposes to demolish the legislation of 40 years. Personally we should prefer the "wisdom" of the least of the Commissioners or of the least of the Commissioners' assistants to this sort of stuff.

Institution Business.

THE annual general meeting of the Institution of Electrical Engineers, which was held on Thursday of last week, did not attract members' attention more than is usually the case. There was but a small attendance and the interest in the whole proceedings was decidedly languid. Of course Mr. F. W. PURSE had something to say about the annual accounts and to make his plea (it is becoming his annual plea) for the reduction of the subscriptions, but apart from that everyone seemed satisfied and the proceedings were soon over. They would have been over sooner but for the fact that the commemoration number of the "Journal" had delayed the printing of the Report. This, therefore, had to be read in abstract, but may well be studied at leisure.

The Annual Report.

The most interesting paragraph in the Annual Report, with which we deal elsewhere in this issue, is that relating to the organisation of a National Electrical Convention. That such a Convention should be held regularly is a suggestion that has often been put forward in these columns. It has also received much unofficial support from the leaders of the profession and was officially commended by Major H. RICHARDSON in his Presidential Address to the Incorporated Municipal Electrical Association last year. It will also be generally agreed that the Institution, with its 10 000 members, is the proper body to make the first move in the organisation of such a gathering, which can only be productive of good. If the Institution leads others will follow. But we hope our proposal that the actual work of organising this function should be placed in the hands of a representative *ad hoc* committee will be adopted. The appeal of this conference should be of the widest; it should be popular and it should be well advertised. This is a special task which will require special treatment.

The British Empire Exhibition.

Fortunately, to work on these lines will be made easier by the decision to synchronise the holding of the conference with the postponement of the date of the British Empire Exhibition to 1924. This will give time for consideration and will have the added advantage that an international flavour can be given to the proceedings. Mr. DUNLOP has done a good deal of spade work in organising the electrical section of the exhibition and full advantage should be taken of his work and efforts to make this larger idea a success.

Otherwise there is not much of note in the report. This is not due to any relaxation on the part of the Council but is rather due to the way in which decisions and policies are announced as they fructify. The report tends more and more to become a record and less and less an out-of-date newspaper.

The Informal Meetings.

We are glad to see that a word of commendation is given to those responsible for the informal meetings. These can be, and are, of the widest use to all classes of members and their usefulness is likely to increase. The depressed state of the industry is indicated by the increase in the number of members on the unemployed register from 51 to 120. We hope that all those who can will take the most decided steps to reduce these numbers. That highly trained men should at the present time be out of employment proves clearly that something is wrong with the machine.

The Electrical Proving House.

Another development that is, we suppose, delayed until better times shall dawn is the establishment of the electrical proving house. We hope that something will be done about this before long. It is as essential as standardisation, whose claims are now recognised, for the well-being of the electrical industry.

Electrical Engineering Training.

It is interesting to find that the claims of the Institution to have a voice in the organisation of engineering training has been recognised by the Board of Education. A well thought out scheme of suggestions on this matter has been made and is under consideration. And, as the report rightly says, the matter is one of the very greatest importance, we hope some early decision will be arrived at. There is perhaps no part of our educational machine which requires more overhauling than that which concerns the preliminaries of scientific and technical education.

Finance.

As regards finance, the balance on the cash accounts is rather less than last year, doubtless owing to the expenses caused by the return to the new building; but generally the finances are in a sound enough state. The same may be said of the Institution. The affairs are well directed, and it is now thoroughly representative of all phases of electrical interest.

The International Railway Congress at Rome.

Some Impressions of the Discussions on Electric Traction.

By ROGER T. SMITH.

The ninth Congress of the International Railway Association was held at Rome from April 18 to May 3. Owing to the war no Congress had been held since 1910, when the meeting was at Berne. In the interval the "reporters" of the various sections and others have contributed articles on the various "questions" for discussion at the Congress; and under Section II, Locomotives and Rolling Stock, "Question" VIII, dealing with electric traction, have published some very important papers from time to time in the monthly Bulletin of the International Railway Association. Among those contributions may be mentioned the following as being of special importance and value to all interested in railway electric traction.

(1) Report on Electric Traction in America, by George Gibbs, published in Vol. III, No. 12, December, 1921, of the Bulletin.
(2) Report on Electric Traction in Italy, by Alfredo Donati, published in the same December, 1921, number as the American report.
(3) Report on Electric Traction in Switzerland, by E. Huber, published in Vol. III, No. 10, October, 1921, of the Bulletin.
(4) Report on Electric Traction in Holland and in Great Britain in the same October, 1921, number as the Swiss report.
(5) Report on Electric Traction in Sweden and Norway, by M. I. Ofverholm, in Vol. III, No. 11, November, 1921.
(6) Report on Electric Traction in France and Spain, by M. Sabouret, published at the Congress, appearing as the report for all countries except Holland, Great Britain, Denmark, Norway, Sweden, Italy, Switzerland and America.

Valuable Documents.

The three first reports are most valuable documents for the railway electrical engineer and traffic officer, full of statistical information, but also containing the views of the several authors on the general question of railway electrification and the application of those views to the past, present and future equipment of main line railways for electric traction in their respective countries.

It is the duty of the President of each section, who, together with the section secretary and the assistant secretaries, is nominated by the Permanent Commission, although elected by the section, to submit a summary of the various reports prepared by a special reporter appointed for that purpose by the Permanent Commission. The summaries for all the sections are published in the April, 1922, number of the Bulletin of the International Railway Association.

Eight Questions for Discussion.

The summary of the various papers contributed to Question VIII Electric Traction was made by Ernest Gerrard, a vice-president of the Permanent Commission and a reporter for the secondary lines of the Belgian State Railways. The summary ends with a series of eight questions to be discussed at the meeting of the section which is expected to give answers to these questions, thus providing a set of international resolutions or conclusions on certain important points.

These questions included (1) the choice of system as between three-phase, single-phase and direct current, and the circumstances which make the choice of one of them proper; (2) the international standardisation of the costs of working electrified railways and the choice of a unit in terms of which those costs and other statistics could be expressed; (3) the relative advantages of catenary suspension and of simple transverse suspension for the overhead contact line, and (4) whether any particular type of current is more satisfactory than another where two or more locomotives are required to work one train.

The section proceeded to remove from the form in which the questions were put everything which could make the answers to them too definite. The answers were non-committal, and those who wish to see them are referred to the Bulletin of the I.R.A. when it is published.

Opinion and Experience.

But the discussions of these subjects were really interesting, and the value to the British electrical engineers of the meetings under Question VIII was the expression of opinion based on experience of the design, construction and maintenance of hundreds of miles of main line electrified railway by such men as Mr. George Gibbs (Chief Engineer for Electric Traction Long Island Railroad), the President of Section II, Signor Donati (Chief Engineer for the service of electrification, Italian State Railways), M. Huber (Chief Engineer for electrification to the Swiss Federal Railways), M. Sabouret and M. Parodi (both Chief Engineers of the Orleans Railway, the latter chief of the electrical service).

The general impression gained from the discussion on systems was that Mr. Gibbs was almost alone in wishing the section to declare that no one system of electric traction ought to be standardised as applicable in all cases, chiefly because it was assumed that he meant "all cases in one country." All those who spoke from experience appeared ready to argue that no one system was applicable to all cases, but they firmly believed that each European country should choose a system and stick to it.

Italy and the Three-Phase System.

In his paper on the electrification of the Italian State Railways (already referred to), Signor Donati shows that when the Valtellina line was electrified in 1901 the three-phase induction motor was the only motor which se med capable of performing heavy railway service, while when the mountain railways in Piedmont and Lombardy were equipped the problem was to find an equipment for an electric locomotive to give the necessary draw-bar pull with an axle load not exceeding 15 tons. Railways in the foothills of the Alps of necessity have many costly bridges. Axle loads on these bridges are limited to 15 tons. The three-phase locomotive fulfilled these conditions. When later a programme was drawn up which, when completed, will raise the length of main line track electrified in Italy to 2 800 miles, it was found that if any system other than the three phase would save as much as 10 per cent. in the locomotive working costs this would only affect the total working costs by 1·7 per cent. The Italians therefore decided to continue their three-phase system which had served them so well, and the programme is being rapidly carried out. For the most part hydro-electric power stations supply the two contact wires and the rails with three-phase current at 3 500 V between conductors at a periodicity of $16\frac{2}{3}$. The whole output of some of the hydro electric power stations is required for traction, but where an industrial supply is also required from the same station this is given from separate machines at 42 periods or 50 periods. Having effected savings by electric traction of the order of fifty million lire a year in locomotive coal and some million and a half lire in other expenses, the Italians concentrated on the improvement of the three-phase system and to its extension at least throughout Northern Italy.

The Position in Switzerland.

In Switzerland some 500 miles of main line have been electrified mostly on the single-phase system at 15 000 V $16\frac{2}{3}$ periods. The original frequency of 15 is in process of being changed to this standard. Mr. Huber, who is carrying out the electrification of the Federal Railways, was emphatic in stating that nothing would induce the State Railways to alter the decision come to in 1912 to adopt the single-phase system for all their lines as the system most suitable for Switzerland. As in Italy, the power stations are hydro-electric, and even to a greater extent than in Italy the whole output of many of the

stations is required for traction. The railways are therefore free to choose the best frequency for single-phase traction, which has been decided to be 16⅔ periods per second. This frequency is too low for industrial power and lighting, for which the Swiss have adopted the frequency of 50.

France, Belgium, Holland and Sweden.

The French, the Belgians and the Dutch have adopted 1 500 V direct current for electric traction, and though the Belgians and the Dutch have not actually carried out any main line electrification, schemes are being prepared on the basis of a uniform system throughout those countries. The French have co-operative schemes for using the extensive water power in the Pyrenees in the Central Plateau and in the Rhone Valley for the supplies of electricity, both for industry and for railway traction. The Orleans Railway system stretches from the Western Pyrenees to Paris, and both M. Parodi and M. Sabouret insisted that the proper thing to do was to electrify the railways throughout the country on one uniform system. The Scandinavian representative did not join in this part of the discussion, but it is well known that M. Ofverholm is a strong believer in the single-phase system and that it is being used and extended both in Sweden and in Norway. Generally, it may be said that in those countries where coal is an expensive import, and the generation of electricity from water power saves large sums of money in locomotive coal, the single-phase system of electric traction at 15 000 V is favoured. Italy began before the single-phase system was developed, and having spent large sums of money on three-phase equipment, which have proved most successful, and saved large sums in locomotive coal, continues to use the three-phase system because, as previously stated, even if another system saved them as much as 10 per cent. in their annual locomotive expenses the result on the total expenses of running the railway would be insufficient to decide the best system to use.

Single-Phase and Hydro-Electrics.

It is worth while considering why those countries which generate by water power have adopted single-phase. The importance of such large units of plant as are essential for the supply of cheap electricity from steam turbine stations does not exist to the same degree in hydro-electric stations, so that the railway alternating traction supply can be given at the low frequency of 16⅔ periods from part of the plant and an industrial and lighting supply at a frequency of 50 from the rest of the plant without much loss in economy. To obtain the full advantages of single-phase or three-phase traction this low periodicity seems on the Continent to be considered essential.

The Steam Turbine and Direct Current.

Those countries like Belgium, Holland and Great Britain, possessing little or no water power, where electricity for traction must be generated by the steam turbo-alternator, have adopted 1 500 V direct current (including in France 3 000 V in special cases, and in Great Britain a sub-multiple or multiple of 1 500 V), which permits the use of the most economical frequency for steam generating plant, namely, 50 periods, current at this frequency being at the same time most suitable for industrial electric motors and for lighting. The density of main line traffic which it would pay to electrify in Great Britain appears to require from 30 000 to 35 000 kW per 100 miles of double track railway. But with three-phase transmission it is doubtful if one generating station can economically feed to a greater radius than 25 miles. If, therefore, the 100 miles of double track is not contained within that radius, the steam generating station for the railway load alone is too small to be really economical and the combination of the railway load with the industrial load in one station becomes necessary for cheap supply. This steam turbine generator condition is quite different from the water turbine generator condition and illustrates the wisdom of the choice of the direct current system in Great Britain, Holland and Belgium, since the same station can supply electricity for railway traction, for industrial power and for lighting. So far as generating electricity is concerned, France appears to occupy an intermediate position between those countries where the choice of alternating current traction has been made as most suitable and those where direct current has been chosen. With her wealth of water power in the South centre and South-east, and with her intention to extend its present use for industrial purposes to electric traction, the best frequency for generation is not a governing feature. Nevertheless, after full consideration, France has decided to electrify on the direct current system, and the delegates who spoke at the Congress were highly satisfied with the choice.

This is no reflection on the American attitude of wishing to keep the open door—for America. The conditions in America are not the conditions in Europe—above all in Great Britain—and while America is not ready to decide on a uniform system and can go on trying to find the ideal system (which as Mr. Gibbs pleaded must be much better than any existing system) without stopping railway electrification on any of the existing methods, that is not the case in Europe.

No Great Difference in the Systems.

People have talked system so long that they have forgotten that the differences in the cost of working one system, as compared with any other system at present in use, do not exceed one or two per cent. on the total cost of running the railway while other great economies possible from electrifying certain dense main line systems are neglected. The Advisory Committee to the Ministry of Transport very properly left an open door in the matter of the choice of system. It is to be hoped that none of the new groups will use that door until someone has found that ideal system which is so much better than any other that it will be worth while for the railways of the world to scrap all that they have done and are doing in order to adopt it. Meanwhile the lesson to be learned from the discussions and talks at the Rome Congress seems to be that each country's choice as to system appears to have been wisely made to suit the conditions in that country, and that British railways might get on with the job of suburban electrification to meet the conditions of traffic which have overtaken and passed the abilities of steam traction to meet them, and of main line electrification under those particular conditions of traffic which would result in a substantial profit on the capital invested.

Overhead Equipment.

A short discussion on the relative advantages of catenary suspension for the overhead contact wire, as against the method generally adopted on the Italian State Railways, where the two contact wires required for three-phase traction are carried by insulators hung from the string of a bow structure which is itself fixed to the bracket arm of a post. These brackets are symmetrical either side of the post, and as many as 10 tracks have their twin contact wires so supported from one post. The maximum speeds on the Italian State Railways are not high, the latest electric locomotives having four speeds of 23, 31, 46 and 62 miles per hour, but it must not be forgotten that with three-phase traction, unlike single-phase or direct current traction for which the series motor is standardised, the speed is constant and the average speed and the maximum speeds are the same independently of grades. These maximum speeds are therefore also the average speeds, and compare with the average and not with the maximum speeds of steam or of electric traction by other systems. The general result of the discussion on contact wire suspension was that whereas the cross suspension adopted by the Italian State Railways was obviously a success with their speeds, nothing but catenary suspension was suitable for the higher speeds used in other countries with other systems.

On the question of a standard unit by which all the statistical and financial results of electric traction could be measured in all countries alike, the section adopted a motion by Sir Henry Fowler referring the question of the standardisation of the method of keeping accounts and statistics to a special commission to be set up by the Association under Section II.

No conclusion was come to as to whether any one system of electric traction was better than any other system in the case with which two or more locomotives could be employed in moving one train, it being generally considered that system had little or nothing to do with this matter and that such "multitraction" is equally satisfactory with all three systems.

Such are one delegate's impressions, for what they are worth, of the discussions at the electric traction meetings. The great use of such a Congress is not so much the official conclusions come to as the interchange of ideas and experiences with men engaged in the sale of transport in other countries where conditions are quite different from our own and the inspection and travel which make those conditions evident. Delegates who were neither reporters nor secretaries had also the opportunity of seeing beautiful things for part of every day and for the whole of some days, and it is possible that the uplifting of the spirit in the atmosphere of so much beauty, whether the work of nature or of man, may have done as much for the delegates as the Congress itself.

Some Reflections on the Lead Hydrate Accumulator.

By W. R. COOPER, M.A., B.Sc.

There is considerable difficulty in expressing definite views upon any new secondary cell when the critic is armed merely with a nodding acquaintance or a brief introduction to the newcomer. As a rule, the virtues that are claimed can only be decided in the light of a somewhat lengthy experience, running, it may be, into years. On mere inspection one can only say that a claim is possible, probable or improbable, as the case may be; or even impossible, if the inventor is sufficiently rash. The cautious inquirer, however, is generally loath to state frankly that some particular claim is impossible, for there have been many false prophets in the history of electro-technics. On the other hand, the history of the lead accumulator consists largely of magnificent claims which have failed to materialise; and although there has been progress over lengthy periods, and very solid progress too, this has been of the slow variety, and we have long since ceased to expect any claims of a revolutionary character. Readers of the technical press have therefore been somewhat startled recently to learn that the Lead-Hydrate Accumulator has properties far superior to those of other lead cells. Although it is not proposed in the present article to say just what this new cell can, or cannot, do (for the writer has not had the opportunity of deciding these points experimentally), it may be useful to consider some of the claims in the light of common knowledge.

Claims Examined.

First let us take the name. Upon first hearing the name "Lead Hydrate" Battery one is apt to suppose that lead hydrate is the active material. Since, however, sulphuric acid is the electrolyte there is no reason to suppose that we are dealing with any other cell than the well-known lead accumulator. The active material is still lead and lead peroxide on the respective plates. Consequently, the name can only mean that a special material has been used, like unto the old name "Chloride," which is still with us, although the cells so designated have for very many years ceased to have any acquaintance with chlorine. It would be equally pointed to call cells which contain ordinary pasted plates by the name "litharge" or "red lead." Still, a name is often commercially valuable, particularly if the buyer is led to wonder what it means.

So-called lead hydrate, so far as the author is aware, is not a novel ingredient. Perhaps it would be more correctly described as impure lead hydroxide. From the small amount of information that has been made public, the oxide in the present instance appears to be made directly from pure lead, and is lead sub-oxide, Pb_2O. This readily takes up moisture and changes to a mixture of the higher hydroxide and metallic lead. A paste of this material with water is suitable for pasting grids, and the plates so obtained can be "formed" electrolytically into positives and negatives in the usual way. Briefly, this is the Lead Hydrate Battery as made by Mr. C. W. Jenner, to whom the present development is due.

Certain Limiting Factors.

It is claimed that a much greater capacity is obtained by this method of manufacture. If this is actually the case it means that the material pasted on to the grid is utilised to a much greater extent than hitherto. This high degree of utilisation has always been the aim of every manufacturer. The difficulty is that the chemical actions involved are mainly surface actions, and consequently efficient utilisation of the material demands a high degree of porosity. This is not, however, the only difficulty. High porosity has often been attained, but beyond a certain point it leads inevitably to lack of strength; and, when this point is passed, disintegration and diminution of life are the inevitable consequences. But it does not follow that all methods of obtaining porosity give the same degree of weakness for the same degree of porosity. Any such idea is disproved by the superiority of present day batteries as compared with those of some 20 years ago. It may be that the paste obtained by the lead hydrate method may lead to greater porosity and to superior results.

Perhaps it may be well to point out that the porosity must in any case be sufficient not only to admit the electrolyte, but also to provide space in which the lead sulphate (and also peroxide) can be formed without blocking up the pores and thus preventing further action.

It may now be desirable to form some idea of what has hitherto been done, and what remains yet to be done, to secure the maximum utilisation of the active material.

Theoretical Limits.

Theoretically 1 ampere-hour should be obtained by converting 3·86 grs. of lead into lead sulphate; or 1 kilogramme of spongy lead should give 260 ampere-hours. Translating this into the more familiar unit of weight used in these matters it may be said that theoretically 1 lb. of spongy lead should give 102 ampere-hours, and 1 lb. of lead peroxide should give 117 ampere-hours. Actually, the capacities obtained are only about 25 per cent. of these figures; or, say, 25 for spongy lead and 30 for lead peroxide. This does not, however, mean that the specific output, expressed as watt-hours per pounds of complete cell could theoretically be four times the present figure (assuming that the character of the electrolyte remains the same), for there are many parts of the cell which would not be correspondingly affected by such an improvement.

In order to facilitate approximate calculations we may assume a mean figure of, say, 110 ampere-hours per pound of lead or lead peroxide, so that half this figure or 55 ampere-hours per pound of *total* active material (spongy lead plus lead peroxide) is the theoretical maximum. The figure is, of course, halved because both kinds of active material are required together. The percentage of active material in light pasted plates of the traction type varies somewhat with the make and with the plate, and is not necessarily the same in both plates. We may assume that the active material averages, say,

56 per cent. of the total weight of the formed plate, whether positive or negative. The figure varies, but the one here taken is commercially realised. If we start with a certain weight of active material, we must then add the weight of the grids, and something for the weight of the box, connections, separators, etc., leaving the electrolyte as the sole remaining ingredient. The weight of these sundries may be taken at, say, 12½ per cent. of the weight of the plates, but will be less in the largest cells. In round figures this means that the weight of grids + sundries is equal to the weight of the active material. The weight of the electrolyte depends simply on the range of specific gravity that is permissible. What is necessary is a certain weight of H_2SO_4 which may be removed by the action of the cell to provide the assumed number of ampere-hours. The calculation is not quite straightforward, because water is formed at the same time as H_2SO_4 is removed. On these assumptions the weight in terms of active material works out as shown in Table I.

TABLE I.—*Active Material Utilised, 25 per cent.*

	Lbs.
Assumed weight of total active material	1
Grids, connections, etc., 100 per cent. of active material ..	1
Electrolyte, assuming 13¾ amp. hrs. per lb. of total active material (*i.e.*, 25 per cent. of the active material is utilised) and range of spec. gr. from 1·280 to 1·170	0·65
Total	2·65

Assuming an average voltage of 1·95, this gives a specific output of 13·75 × 1·95/2·65 or 10·1 watt-hours per pound of cell at the 10-hour rate. Taking 1·93 volts as the average voltage at the 5-hour rate, and a drop in capacity of, say, 12½ per cent., the specific output at this rate is 8·8 watt-hours per pound.

Some readers may say that such calculations are not dependable; and in order to reassure the faith of such doubters it may be said that figures of this kind are not uncommon. They are, in fact, a little low, as an output of 10 watt-hours per pound at the 5-hour rate would, no doubt, be expected. This may mean that the conditions in practice are a little more favourable than those which have been assumed. But probably the difference is due to the fact that the acid range is really greater. The strength of acid in the pores of the active material is always greater or less, as the case may be, than that of the free electrolyte, because diffusion takes time.

Possibility of Securing Improved Results.

We may now consider how far these results may be improved with a given electrolyte. For this purpose there are two main lines of attack, one being to increase the extent to which the active material is usefully employed, the other being the reduction of the weight of the grid as compared with the weight of the active material. The results that are theoretically obtainable are shown in Table II.

TABLE II.—*Theoretical Outputs on Certain Assumptions.*

No.	Assumptions.			Weight in lbs.				Watt-hours per lb.	
	Active material utilised.	Grid. % of Plate.	Acid Range.	Total Active material	Grids, Box, etc.	Electrolyte.	Total.	10-hr. rate.	5-hr. rate.
1	25%	44%	1·280-1·170	1	1	0·65	2·65	10·1	8·8
2	50%	44%	1·280-1·170	1	1	1·3	3·3	16·3	14·0
3	75%	44%	1·280-1·170	1	1	1·95	3·95	20·4	17·6
4	100%	44%	1·280-1·170	1	1	2·6	4·6	23·3	20·2
5	50%	22%	1·280-1·170	1	0·44	1·3	2·74	19·5	16·9
6	100%	22%	1·280-1·170	1	0·44	2·6	4·04	26·5	23·0
7	25%	44%	1·350-1·170	1	1	0·41	2·41	11·8	10·2
8	50%	44%	1·350-1·170	1	1	0·82	2·82	20·2	17·4
9	75%	44%	1·350-1·170	1	1	1·22	3·22	26·6	23·0
10	100%	44%	1·350-1·170	1	1	1·63	3·63	31·4	27·2
11	50%	22%	1·350-1·170	1	0·44	0·82	2·22	25·7	22·1
12	100%	22%	1·350-1·170	1	0·44	1·63	3·07	37·2	32·0

Taking first the case of electrolyte with a working range of 1·280–1·170 and the grid forming 44 per cent. of the plate on the average, then if the active material is utilised to the extent of 50 per cent., instead of 25 per cent., the watt-hours per pound rise from 10·1 to 16·3. If the utilisation could be brought up to 100 per cent. the watt-hours per pound would only rise to 23·3, which seems a comparatively low figure.

If the grids were made relatively lighter, say half the weight, making 22 per cent. of the plate, and if the active material were used to the extent of 50 per cent., the watt-hours per pound would rise to 19·5, as against 16·3 in case No. 2. The corresponding figure for 100 per cent. utilisation is 26.5. In looking at these cases of high utilisation it will be noted how increasingly important the weight of the electrolyte becomes, being now well over 50 per cent. of the whole. It becomes evident that the only means of further progress is the use of a wider range of specific gravity.

The Use of Strong Acid.

One of the surprising features of the Lead Hydrate Cell is the use of unusually strong acid. The range of specific gravity in charging and discharging is stated to be 1·300–1·350. Such strong acid has hitherto been avoided because it tends to "self discharge," and the author is not acquainted with any manufacturer who would contemplate for a moment the use of such strong acid. In the case of lead cells of the usual type for automobile working the upper limit for the acid has commonly been 1·280, and often lower. The object in this case has been to reduce the weight of the electrolyte as far as possible; and since this can only be done by eliminating some of the water, a large working range is adopted, the lower limit of specific gravity being, say, 1·170, or somewhat lower. If the lead hydrate plates can stand up against an acid strength of 1·350 the cell should be capable of working through the great range of, say, 1·170–1·350, which would reduce the weight of electrolyte appreciably. The average voltage on discharge would also be greater, being, say, 2·07 volts for the 10-hour rate, instead of 1·95; and 2·05 volts for the 5-hour rate as against 1·93. This leads to a still greater output, but has the disadvantage that the variation of voltage over the discharge is necessarily greater. It should also be noted that the internal resistance of the cell is materially increased by the use of very strong acid, but the voltage drop becomes less as the acid becomes diluted, and therefore the discharge curve is flatter than would otherwise be the case.

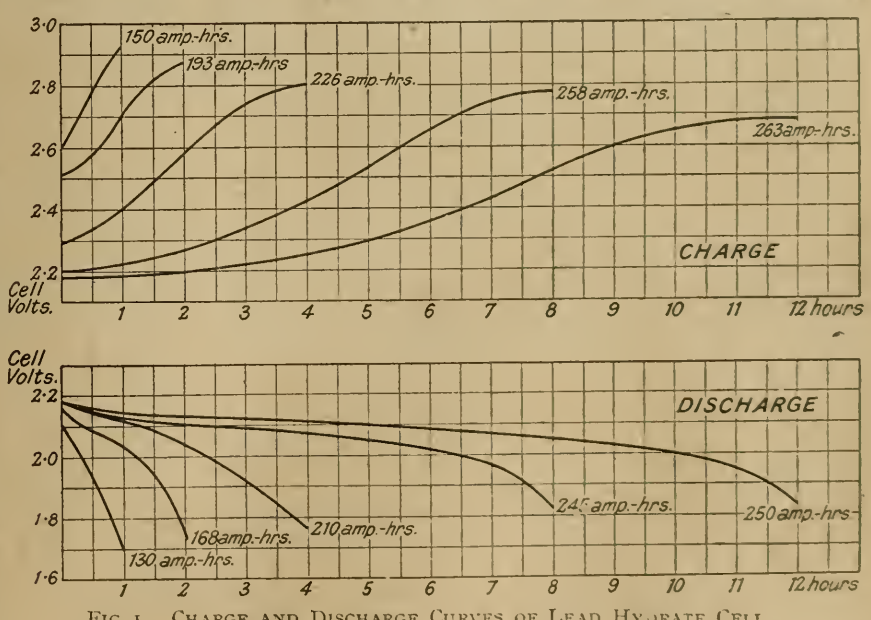

FIG 1. CHARGE AND DISCHARGE CURVES OF LEAD HYDRATE CELL.

Discharge Curves.

The results thus obtainable are shown in the lower half of Table II. There is a very considerable gain by the use

of the stronger acid in this way. But, curiously enough, the makers of the Lead Hydrate Cell state that the acid range is only 1·350–1·300, which means that the chief advantage of the stronger acid is not secured. This view is not altogether supported by the published discharge curves, which are reproduced in Fig. 1. Here the discharge starts at about 2·18, which is what would be expected having regard to the strength of the acid; but, although the voltage is maintained high for the greater part of the discharge it finally falls to about 1·83 volts at the 12-hour rate, which is about the commonly accepted figure for other cells. Now, for this low value the strength of acid should be, say, 1·170. If the acid does not fall below 1·300, or thereabouts, the only explanation of the phenomenon appears to be that the weak acid in the pores of the plates (which are stated to be much thicker than usual, up to $\frac{1}{2}$ in. for positives and $\frac{5}{16}$ in. for negatives) has not had time to diffuse out, and that the plates are really working in much weaker acid at the end of the discharge than is apparent. It is also noticeable that the capacity at the 12-hour rate is not as large in comparison with that at the 1-hour rate, as is usual, and this may possibly be due to some similar cause.

It will be noticed that, even under these conditions, carried to a very high ideal, the highest output is 37·2 watt-hours per lb. The author does not wish to set any particular limit beyond which we must not expect to go, for there may be conditions, or even new reactions, which cannot be taken into account in an analysis of this kind. But the figures here given are sufficient to show the great practical difficulties that are ahead of anyone who claims revolutionary results.

Purity and Sulphating.

The Lead Hydrate Cell is stated to be immune from "sulphating," and this characteristic is attributed to the purity of the active materials and consequent elimination of local action. It will be conceded at once that any local action must cause the plate containing the impurity to become discharged more or less slowly. But it is not at all so clear that "sulphating" is only due to local action. In fact, but little is known as to the real difference between "sulphate" and the normal lead sulphate that must be formed in the action of the cell. Be this as it may, we may bear in mind that other types of lead cell are also capable of remaining on open circuit for considerable periods without adverse effects, and that if greater purity gives advantages that are worth the money, the litharge and red lead that are commonly used in the manufacture of pasted plates can also be made highly pure, so that such advantages are open to any maker of lead cells.

As already stated, the active materials must in any case be spongy lead and lead peroxide, just as in every other lead cell. When the statement is made that the active material derived from lead hydrate does not change its volume under any condition of charge and discharge, and therefore no buckling can take place, it may perhaps be well to point out that certain changes in volume are inevitable. Both spongy lead and lead peroxide increase in volume when they are converted into lead sulphate, and the further this conversion is taken the more the pores of the active material are closed. This change is more serious with lead peroxide than with lead. Buckling will take place if this closing up of the pores is carried so far, and so unequally, as to set up serious stresses on one side of the plate. It is clear that if the porosity is sufficiently high no such stresses will arise. In any case the active material does not change its volume as a whole in normal working, but whether the active material of the Lead Hydrate Cell is so porous that no internal stresses can arise, the writer is not in a position to say.

The two statements that the battery is (1) indestructible and (2) that it has a much longer life than that of any other battery seem a little incompatible; or perhaps it would be more correct to say that the second statement is somewhat unnecessary if the first is true. The average cell comes to an end of its life through various causes, of which one of the most important is the shedding of active material. This is due largely, no doubt, to the persistent mechanical action of gassing, and it is usual to provide a considerable space in accumulator boxes so that the shedded material may collect without remaining in contact with the plates.

Electric Automobilism.

Some remarkable claims are made for the Lead Hydrate Cell in automobilism. In this connection it is well to remember that the specific output of a cell (or watt-hours per pound) is related very simply to the distance that can be travelled on a single charge. Assume that a specific output of 11 watt-hours per pound at the 5-hour rate is the specific output for ordinary lead cells, and assume that an electric vehicle requires on the average 110 watt-hours per ton-mile (which is about the figure for large commercial vehicles). Then 1 lb. of battery will give energy sufficient to run one-tenth of a ton-mile, or 224 pound-miles, or will propel 1 lb. for 224 miles. In other words, if a battery could be mounted on a massless chassis it could run 224 miles on a single charge. Actually the chassis will weigh, say, twice the weight of the battery, and the limiting distance is reduced to one-third, or, say, 75 miles; and in ordinary practice this becomes, say, 50 miles when the vehicle is loaded. Cells have been made, and are still listed, with an output of 14 watt-hours per lb., and with such cells the distance would be correspondingly increased, but this figure tends to fall as the cell becomes older.

According to figures which have appeared, the specific output of the Lead Hydrate Cell is over 27 watt-hours per pound, but this is at the 12-hour rate. The corresponding figure for the 5-hour rate may be taken as about 24 watt-hours per pound. This high specific output, if realised in practice, would be of great value and would mean that the distance an electric vehicle could travel on a single charge would be increased to about double the distance hitherto possible; or, say, 100 miles instead of 50 miles, or perhaps 150 miles instead of 75 under special conditions. This would be a marked advance, but it is very much less than the advance from 50 miles to 300 miles, as suggested in a recent article. The latter would require a specific output of six times what is now obtained, or something between 60 and 84 watt-hours per pound. But such a figure seems quite impossible, as already shown, even if the cell consisted only of active material and electrolyte worked over a large range—*i.e.*, if the grids, box, connections, etc., weighed nothing. The vehicle, of course, may be improved, so as to run more economically, but this will not alter relative positions.

It is also claimed that the cell can be recharged in 15 minutes. But does anyone want this? What would be the temperature of the cell? And would the station engineer be prepared to give charging currents at this rate?

Messrs. Siebe, Gorman and Co., who are manufacturing the new battery, are a firm of repute and are allied with Vickers, Ltd., so that we may reasonably suppose that all claims have been amply substantiated. On the other hand, for the reasons here given, the writer finds it difficult to accept some of the statements that have appeared. As already stated, time alone can decide whether many of the claims are justified, and pending this slow process of justification most users and manufacturers alike will prefer to await the verdict of time before accepting the view that the art of the lead accumulator has been wholly revolutionised.

The "Anglo-Swiss Review" states that the new electric transmission line, lately erected between Monthey (Valais) and Forclaz (Vaud) is connected with the Fridbourg transmission cables on one side and, on the other side, with the Monthey-Brigue cable. The latter conveys 45 000 H.P., and the surplus can be diverted over the Alps to the Fribourg and Berne cables. The Monthey-Forclaz cable is the last of the four connecting the power stations on the south of the Alps with those on the northern side; one runs through the Bernina, a second through the St. Gothard, a third over the Gemmi Pass.

Correspondence.

"BROADCASTING" PIONEERS.

To the Editor of THE ELECTRICIAN.

SIR,—In your Editorial Notes of May 19 you cite the Westinghouse E. & M. Co., of Pittsburg, as "the pioneer of radio broadcasting."

Their work along this line began in 1921. How many months, or weeks, are required in such an advancing art as radio to qualify one as a "pioneer"?

In 1909 the first "broadcasting" station was installed on the roof of the Metropolitan Opera House, N.Y.C. It was a temporary affair to seek to interest the Opera Company directors in my project of a free distribution of good music by radio-telephone. Microphones were installed in the footlights, and wires run to the arc transmitter on the roof. I recall that "Cavalleria Rusticana" was the opera chosen for the first broadcasting—and Caruso, as Turiddu, was thus the first singer whose voice was broadcasted.

The music from these first radio operas was picked up by ships near N.Y.C., but the cult of American Amateurs had then scarcely seen light, and lacking an audience this demonstration was logically shortlived.

There was more or less sporadic broadcasting from several San Francisco radio telephone stations, 1910–13. In 1916 the De Forest Radio Telephone Co. began a regular nightly radio programme, chiefly phonograph music, from its Highbridge, N.Y., plant, which service was maintained regularly until approach of our war cloud led the Government to close down all but official stations.

On "Election Night," November, 1916, two-minute bulletins of the election returns were broadcasted for several hours, being picked up as far west as Buffalo.

About this time the first "Radio Dances" were begun—parties in New Jersey, 35 miles distant, danced to music played in Highbridge. In 1920 the first regular broadcasting station in connection with a theatre was opened by my company in San Francisco, this service being maintained ever since. Each afternoon and night, and also on Sunday mornings, the very excellent orchestra music of the California Theatre is picked up by microphones carefully designed and located to best catch the various instruments, transmitted to an upper room, and there "put on the ether."

These concerts are frequently heard as far as Seattle and Los Angeles, and by ships half-way to Honolulu.

To some little mountain villages, where an enterprising amateur has an amplifier and loud speaker, ranchers drive in for miles to hear the Sunday morning concerts played in San Francisco.

It is indeed a keen gratification to observe how enthusiastically that early idea of radio-phone broadcasting has, at last, "caught on."—I am, etc.,

LEE DE FOREST.

THE SEA RETURN OF A SUBMARINE CABLE.

To the Editor of THE ELECTRICIAN.

SIR,—On going over the interesting work of Messrs. John R. Carson and J. J. Gilbert on "The Sea Return Impedance of a Submarine Cable" referred to in your issue of April 28, 1922, may I be permitted to note that the form of solution given obtains only for stationary waves, as against a combined stationary-progressive wave on the cable.

In view of the fact that hysteresis, real or effective, plays quite an important part, especially in connection with high-frequency phenomena, it would seem that a loss of generality results by taking account only of the usual R L G C line parameters.

In a paper which appeared in the April, 1921, issue of the Journal of the I.E.E. on "The Radiation Resistance of Various Types of Antenna Construction," the writer disclosed a mathematical method taking elliptical hysteretic phenomena into account. As a consequence, on page 441 of the above journal, it stated that "it appears that the voltage-distribution curve lies on a rotating helical sheet winding about the antenna as an axis." In the Carson-Gilbert case, where hysteresis, real or effective, is ignored, the locus lies in a rotating plane passing through the antenna as an axis.

The above distinction is of some consequence in cable and antenna work as the writer has later pointed out mathematically. For in the general case considered it was necessary not only to solve Maxwell's equations for the field external to the line conductors, but also at one and the same time satisfy the line characteristic *à la* Heaviside. This study was made possible by making use of the concept of complex capacitances and inductances.—I am, etc.,

ELECTRIC PROPULSION METHODS.

To the Editor of THE ELECTRICIAN.

SIR,—It is interesting to note in your current issue (May 12, 1922) that the new U.S. super-Dreadnoughts are to be driven by two-speed motors, at 23 knots and 15 knots. This speed ratio is met by the "Cascade" Motor with a single winding. Yet our American friends obtain this result "by the use of two entirely separate stator and rotor windings." At the present moment there is a strong likelihood of two-speed "Cascade" motors being used on British-driven ships in the near future.—I am, etc.,

ERNEST W. ASHBY.

Hawarden,
May 19, 1922.

HENLEY'S CABLES.

To the Editor of THE ELECTRICIAN.

SIR,—We regret that there was an error in our advertisement on the front cover of your journal last week, and we trust you will grant us the hospitality of your columns to correct it. We described the illustration of the 33 000 V. Birmingham cable as a "Split Conductor" cable. This, of course, is not correct. It is a three-core cable for use with a pilot, on the Beard-Hunter System of Automatic Protection.

We always endeavour to state only the truth in our advertisements, and we regret that this rather silly slip should have got in.—I am, etc.,

W. T. Henley's Telegraph Works Co., Ltd.,

Exponentials Made Easy.

Some fifty years ago the teaching of mathematics in this country suffered severely from programmes rigorously mapped out, departure from which meant loss of official recognition. In the old days every Cambridge student had to learn Euclid's proofs, and in the first part of the mathematical tripos the student was forbidden to use the calculus. It was no wonder that many gave up the study of mathematics altogether once they had got through their examination, the official diet provided having proved both uninteresting and indigestible. Then Perry, and later on Silvanus Thompson, made the study—at least for engineering students—more attractive. They laid stress on its practical applications and successfully showed that many mathematical theorems were of human interest and could be understood by the average reader without much difficulty.

This volume* is written as a companion volume to Silvanus Thompson's "Calculus Made Easy." The titles of the various chapters indicate the way in which the author treats the subject. For example, the titles of Chapters IX., XI., and XIII. are "Epsilon's Home: The Logarithmic Spiral," "Epsilon on the Slack Rope: What there is in a Hanging Chain," "Where Epsilon Tells the Future: The Probability Curve and the Law of Errors." We welcome a book of this nature. It will clear up some of the mathematical difficulties of the junior reader, and will both widen his knowledge and encourage him to make further mathematical research. It is both well written and accurate.

A. R.

* "Exponentials Made Easy, or the Story of Epsilon."—By M. E. J. Gheury de Bray. (Macmillan & Co., Ltd., 1921.)

Institution of Electrical Engineers.

Annual General Meeting.

The Annual General Meeting of the Institution of Electrical Engineers was held on Thursday, May 25, at the Institution building, the President (Mr. C. S. Highfield) in the chair.

The PRESIDENT, commenting upon the Council's Annual Report (which is abstracted below) said the Council had just managed to arrange to have the ceremony of unveiling and dedicating the Institution's War Memorial on June 28, the Wednesday just preceding the Conversazione.

He then announced the following awards of premiums for Papers presented to the Institution during the session.

Institution Premium of £25 to Mr. J. G. Hill, for his paper on "Phantom Telephone Circuits and Combined Telegraph and Telephone Circuits Worked at Audio Frequencies." *Ayrton Premium* of £10 to Mr. L. H. A. Carr, for his paper on "Induction-type Synchronous Motors." *Fahie Premium* of £10 to Mr. E. S. Byng, for his paper on "Telephone Line Work in the United States." *John Hopkinson Premium* of £10 to Mr. F. P. Whitaker for his paper on "Rotary Converters, with special reference to Railway Electrification." *Kelvin Premium* of £10 to Mr. P. Torikai, for his paper on "Abnormal Pressure Rises in Transformers, and its Remedy." *Paris Premium* of £10 to Mr. J. A. Kuyser, for his paper on "Protective Apparatus for Turbo-Alternators." *Willans Premium* of £14 6s. to Mr. K. Baumann, for his paper on "Developments in Steam Turbines." *Extra Premium* of £10 to Mr. F. J. Teago, for his paper on "Test Results obtained from a Three-Phase Shunt Commutator Motor." *Extra Premium* of £5 to Mr. J. Anderson, for his paper on "Electric Motor Starters." *Extra Premium* of £5 to Mr. W. Wilson, for his paper, "Some Notes on the Design of Liquid Rheostats." *Duddell Premium* of £20 to Mr. T. L. Eckersley, for his paper on "An Investigation of Transmitting Aerial Resistances." *A Premium* of £10 to Mr. E. M. Moullin and Mr. L. B. Turner, for their paper on "The Thermionic Triode as Rectifier." *A Premium* of £10 to Mr. C. S. Franklin for his paper on "Short-Wave Directional Wireless Telegraphy."

Mr. HIGHFIELD, resuming his comments on the Report, said he had visited all the Territorial Centres except Glasgow, which he would visit next week, and Dublin, to which he had not been asked to go. In every centre he found the same keenness for the well-being and good name of the Institution that was found at the meetings in London. Members of other societies envied the radio-active qualities of their membership. He was glad to say nothing had been done in the way of exacting German reparations by requiring Germans to put up electric power stations here. With regard to electrical engineering training and examinations, the Committee, of which Mr. Gill was chairman, hoped to put a scheme forward which would be useful to the Students. There was a gratifying increase in the number of subscribers and donors to the Benevolent Fund, the total being 1 351 during the past year, compared with 884 in the previous year, while the sums they contributed amounted to £1 693, compared with £440.

The Report having been adopted, Sir JAMES DEVONSHIRE (Hon. Treasurer) explained and moved the adoption of the Accounts, and, after some remarks by Mr. F. W. PURSE, who referred to the increased revenue, increased contributions to reserve, &c., and suggested that the Council should consider the question of reducing members' contributions, the motion for the adoption of the Accounts was agreed to.

Votes of thanks were accorded the Hon. Secretaries of Local Sections, the Hon. Secretaries abroad, the Hon. Treasurer, and the Hon. Solicitors, and Messrs. Allen, Attfield & Co. were reappointed Auditors.

Annual Report.

Membership of the Institution.

After references to the Royal Charter, the new seal, and the liquidation of the old Institution, it is stated that on April 1, 1922, the total number of members of all classes was 10 275, a net increase of 826.

The average annual increase of membership for the last three years is over 1 000, and the Council express gratification at this rapid growth, notwithstanding the increasing stringency of the qualifications for admission.

Deaths.

The deaths of 54 members occurred during the year. Amongst them were M. J. Carpentier, Prof. F. B. Crocker, Dr. Edward Hopkinson, and Mr. R. E. Winkfield (Past Chairman of Calcutta Centre).

A design for two bronze tablets to be placed in the entrance hall has been approved as a war memorial. The War Memorial Book containing the biographical notices and portraits of members who fell in the war is now in an advanced state of preparation. The editing of the book has been undertaken by Lieut.-Col. W. A. J. O'Meara.

Wireless Aerial on Institution Building.

On the recommendation of the committee of the wireless section, a permanent aerial has been erected on the Institution building, the dimensions of which we have already given. The natural wavelength is about 200 metres.

National Electrical Convention.

The Council have approved a suggestion made to them that a National Electrical Convention be held under the auspices of the Institution. In view of the postponement of the British Empire Exhibition to 1924, the Council will reconsider the question of the date for the first Convention.

Territorial Centres and Sub-Centres.

The attendance reported at the meetings held at the Territorial Centres and Sub-Centres afford evidence of the interest taken by members outside London in the work of the Institution. During the Session the President paid visits to the Centres at Birmingham, Cardiff, Leeds, Manchester and Newcastle, and to the Sub-Centres at Loughborough, Liverpool and Sheffield. The Council regret the discontinuance of the Aberdeen Sub-Centre on account of the small number of members in that district.

Mr. R. V. Picou has resigned the office of Local Honorary Secretary for France, and Mr. J. Grosselin has been appointed in his place.

Wireless and Informal Meetings.

The Wireless Section of the Institution has held seven meetings, and seven papers were read, and ten informal meetings have also been held. The Council are highly gratified at the success of the latter meetings, and congratulate the Informal Meetings Committee on their excellent work.

Students' Sections.

The number of students on the Register of the Institution has reached a record total of 2 455. The Council have recently granted permission for the formation of Students' Sections at Leeds and Sheffield. The latter Section has held two meetings. A students' tour in Switzerland, organised by the London Students' Section, took place towards the end of July, 1921, and several works were visited.

The following Scholarships have been awarded by the Council: *David Hughes Scholarship*—Mr. W. T. Slater; *Salomons Scholarships*—Mr. G. R. A. Murray and Mr. P. G. A. Voigt.

War Thanksgiving Education Research Fund.

A grant of £100 for educational purposes has been made under the provisions of the Trust Deed to Mr. J. D. Cockcroft (College of Technology, Manchester).

Return Visit of Dutch Engineers.

The return visit of Dutch Electrical Engineers took place from the 23rd to the 28th May last. The party consisted of representatives of the Royal Dutch Society of Engineers and of the Association of Managers of Dutch Electricity Undertakings. After being shown over various places of interest in London, the visitors travelled by motor via Henley, Oxford, Hereford and Chester, and to Manchester.

Library.

After a period of over four years, the Institution and Ronalds Libraries were again accessible to members last summer, and the number of readers from September, 1921, to March, 1922, inclusive, was 1 202, of whom 52 were non-members. The Council have decided to keep the Library open on the evenings on which ordinary meetings of the Institution, informal meetings and meetings of the Wireless and Students' Sections are held.

Electrical Appointments Board.

The Electrical Appointments Board report that the number of unemployed members on the Register is 120, as against a total of 51 last year. The Council hope that firms having vacancies will assist them by reporting them to the Secretary of the Board at the Institution offices.

The Journal of the Institution.

The number of pages in the 1921 volume was 852, compared with 944 in 1920. In addition, a supplementary volume of 336 pages was printed in 1920, making a total of 1 280 pages for that year. The net cost of printing and publishing, after allowing for sales, was £4 936, compared with £6 739 (including the supplement) in 1920. Owing to the trade depression of the past twelve months, the publication in the *Journal* of the Classified Index of British Manufacturers has been delayed, but a preliminary issue will appear at an early date.

The contribution of the Institution towards the cost of publishing *Science Abstracts* in 1921 was £978, compared with £261 in 1920, but the average for the two years was approximately the same as the average annual contribution since its conception in 1898.

Wiring Rules.

The Editing Sub-Committee have completed the revised draft of the Rules, and it is now being considered in detail by the Main Committee. In connection with the revision, specifications for certain electrical apparatus are being prepared by Committees of the British Engineering Standards Association. It is hoped that these specifications will be available before the new edition is finally published, so that reference may be made to them in the Rules. It is proposed to issue the revised "Conductor" section in advance of the remainder of the Rules.

Model Conditions for Contracts.

On the suggestion of the British Electrical and Allied Manufacturers' Association the Council have appointed a committee to prepare model conditions of contract for (*a*) " Home " orders when no erection is included in the contract, and for (*b*) " Export " orders, with or without erection.

Sea-going Electricians.

A deputation of the Ship Electrical Equipment Regulations Committee has been received by the Board of Trade in connection with the steps that are being taken by the Institution, at the request of the Electrical Trades Union, to urge the Board to hold examinations and grant certificates to sea-going electricians.

British Electrical Proving House.

The Wiring Rules Committee have reported to the Council as follows :—

" Very grave difficulty is found by this Committee in dealing with inquiries as to the conformity of appliances and fittings with the Wiring Rules, and the Committee are strongly of opinion that a body for dealing with questions of this kind should be set up, and they recommend the Council to reconsider the question of a National Proving House."

The Council have referred the matter to a committee for consideration and report.

Registration of Electrical Contractors.

The Council have set up a committee consisting of representatives of the Institution and other interested bodies, to prepare and report on a scheme for the voluntary registration or certification of electrical contractors.

Power Lines Committee.

The Regulations Sub-Committee have been engaged in the revision of the Board of Trade Regulations, for (*a*) securing the safety of the Public, and (*b*) ensuring a proper and sufficient supply of electrical energy ; also the Overhead Line Regulations for (*a*) high pressures and (*b*) low and medium pressures. Drafts of the revised Overhead Line Regulations have been completed, and that for high pressure has been circulated amongst the associations interested. Various criticisms and suggestions have been received, and the draft Regulations are consequently being reviewed. A similar course will be followed in regard to the low and medium pressures Regulations, and it is hoped that a report on both sets of Regulations will be ready before next Session.

German Reparation Payments.

On November 17, 1921, *The Times* published a letter from Sir Henry Strakosch proposing that German reparation payments be made in kind, principally in the form of electrical machinery. The Council addressed a letter to the Prime Minister and to the Chancellor of the Exchequer taking strong exception to the proposals.

City and Guilds of London Institute (Grade I).

The Council have been glad to give their support to an application to the Board of Education from the Council of the Electrical Contractors' Association for the temporary reinstatement of the examination in electrical installation work. The Board have granted the application for the year 1922, and have left the question of the future of the examination for discussion between the Board and the Association.

Electrical Engineering Training.

The Council received last year a letter from the Board of Education inviting the Institution to appoint a small body of representatives to discuss with representatives of the Board the possibility of the co-operation of the Institution with the Board in the regulation of courses of study and the issue of certificates and diplomas to successful students.

The Council appointed a committee to meet representatives of the Board, and five conferences were held. As a result a scheme to give effect to the objects in view was submitted to and approved by the Council. The proposals are now under consideration by the Board of Education. The main points of the scheme are :—

(1) The abolition of single-subject examinations and the substitution of grouped courses in electrical engineering.

(2) A joint board of three members appointed by the Institution and three by the Board of Education will be set up to manage the scheme, including the curriculum and the examinations.

(3) The entry of any school into the scheme is entirely voluntary, but no school can be included unless approved after detailed inquiry by the Institution, and such approval may be withdrawn by the Institution at any time, if found necessary.

(4) The holding of internal examinations by the approved schools and of a final internal examination with external assessors appointed by the Institution. These assessors will review the questions set and give the final marks to the answer papers.

(5) National certificates and diplomas bearing the names of the Institution of Electrical Engineers, the Board of Education and the School will be issued to successful candidates.

The Council regard this matter as one of very great importance, tending to bring the schools more closely into touch with the educational needs of the industry, affording a guide to young men as to lines of study, and providing for a certificate, the value of which will be recognisable all over the country.

Similar arrangements have been made by the Institution of Mechanical Engineers and the Institute of Chemistry.

Co-operation among Engineering Institutions.

The Council have appointed the President and Mr. K. T. Smith to represent the Institution at a conference summoned by the Institution of Civil Engineers to examine the question of co-operation among engineering institutions.

Development and Research Association.

The membership of the Association has reached a total of 610. Members of the Institution interested in development work are recommended to communicate with the Director of the Association, who will be glad to give particulars of membership, &c.

The Council of the British Electrical and Allied Industries Research Association now consists of twenty members, of whom seven are nominated by the Institution. The work is divided under eleven sections, and there are over forty research committees. The Association has the regular assistance of about 150 experts and the occasional assistance of many others. The expenditure on research now amounts to about £16 000 per annum.

The B.E.S.A.

Seven British Standard Specifications for electrical purposes were issued during the year.

Considerable work has been done in connection with the co-ordination of the electrical specifications of eight Government Departments, and much of this work will become available for general use.

The revision of the Standardisation Rules for Electrical Machinery (B.S.S. No. 72) has been in progress for over a year, and it has been decided to sub-divide the Rules and draft them in the form of specifications as follows : (*a*) Large machines ; (*b*) transformers ; (*c*) industrial machines. These should be available during the coming year.

The list of " Terms and Definitions " originally prepared by the Institution in March, 1916, has been reviewed and greatly enlarged. It will not be issued until it has been considered by hte International Electrotechnical Commission.

International Electrotechnical Commission.

The changed conditions in all countries have made the work of the International Electrotechnical Commission during the past year proceed at an apparently slower rate than formerly, each country with its own national standardising body now finding it necessary to consult all the various interests before instructing delegates to attend the meetings.

The revision of the I.E.C. standard of resistance of copper has been completed. Proof copies can be seen by those interested on application to the Secretary of the Commission. A corresponding standard for aluminium is in course of preparation.

A request for the co-ordination of the rules and regulations relating to distribution systems (overhead and underground) in the various countries has been acceded to. A questionnaire is being prepared for circulation, and each national committee will be asked to prepare replies.

Benevolent Fund.

On December 31, 1921, the capital account of the Benevolent Fund stood at £7 859 7s. 3d., and the accumulated income at £1 583 16s. 9d. Donations and subscriptions in 1921 amounted to £1 424 17s. 3d.

Grants were made to 14 persons amounting to £525 5s.

Reference was made in the last annual report to the generous offer of Mr. E. M. Hughman (late of Bombay) to present £250 to the Fund, provided 19 other donations of a similar amount were received by June 30, 1921. Mr. Hughman was good enough to extend the date to December 31, 1921, and entirely to waive his conditions, both as to the number and the amount of the other donations. An appeal based on the offer was widely circulated, and the result has been that the Fund has already benefited to the extent of £2 306 6s. 5d.

The Institution's Annual Accounts.

After making provision for contingencies, as in the previous year, there is a margin to the good on the revenue account for 1921 of £639 2s. 10d. This amount, which has been carried to the credit of the general fund, compares with £673 7s. 1d. in 1920. In the accounts for 1920 mortgages stood at £29 284 15s. They now stand at £24 331 19s. 11d.

The total of the Life Compositions Fund on January 1, 1921, was £5 676 11s. Out of this the sum of £86 1s. has been transferred to the general fund on account of Life Compositions of members deceased during the year, leaving to the credit of the Fund £5 590 10s.

Taking the Tothill Street property and the investments at cost, and the Institution building and lease, the library and furniture, etc., at the values standing in the books after writing off depreciation, the assets amount to £115 354 15s. 10d. against liabilities £6 415 7s. 11d., leaving a surplus of £108 939 7s. 11d., which compared with £102 696 0s. 10d. in the previous year.

A diagram is attached to the report. This is a truly imposing list showing the organisation of the Institution and its representation on other bodies.

The Fullagar Oil Engine.

The demand for oil engines of relatively high powers has led the English Electric Company to take up the manufacture of the Fullagar oil engine for the driving of dynamos, water pumps, air compressors, and for similar purposes.

The arrangement of exhaust and air inlet ports used in this engine is diagrammatically shown in Fig. 1. Here there are two pistons moving in opposite directions in one cylinder—one piston first uncovers the exhaust ports, which extend all round the cylinder bore, then the other piston uncovers a set of scavenge ports at the other end of the cylinder. These ports also extend all round the bore, and fresh air at a low pressure, supplied by a pump, flows from one end of the cylinder to the other, sweeping out the burnt gases and leaving the cylinder filled with fresh air. This method of scavenging has been used for many years by the employment of three cranks per cylinder, the centre crank being connected to the piston nearest to it, and the two outer cranks coupled to the piston more remote.

The special feature of the Fullagar engine consists in having only one crank and connecting rod per cylinder, in place of the cumbersome arrangement of three cranks just described. Fig. 2 shows two cylinders exactly similar to that in Fig. 1, each having two pistons working in it. By connecting the lower piston in the first cylinder to the upper piston in the second cylinder, and the lower piston in the second to the upper piston in the first by pairs of oblique rods external to the cylinders themselves, the need for three cranks per cylinder is overcome.

Further Advantages of the Engine.

Apart from the air scavenging arrangements, the following are among the many advantages obtained from the Fullagar system of

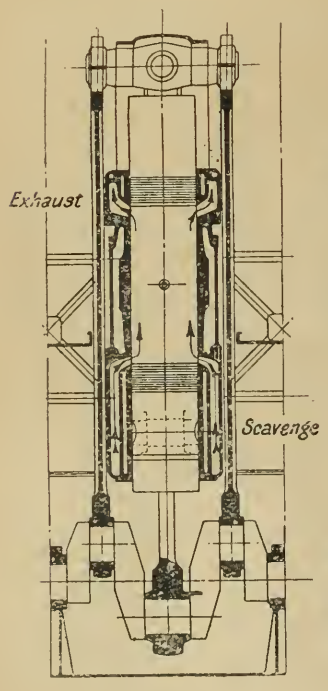

Fig. 1.

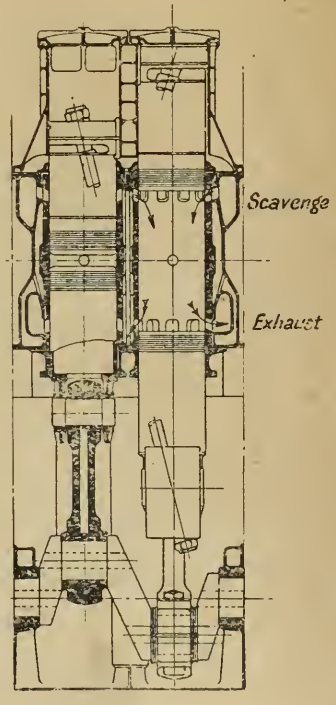

Fig. 2.

opposed pistons cross-connected: (1) the direct stresses caused by the pressure between the pistons are not transmitted to the framing. There is thus an important saving in weight, the stresses on the framing being only those due to the side thrust of the upper and lower crossheads; (2) the work which has to be expended in compressing the air in the cylinder adjoining that in which combustion is taking place is done directly by means of the external oblique rods, instead of being transmitted through the crankshaft, as in all other types of engine; (3) the lubrication of the main bearings of the crankshaft and the connecting rods is rendered easier by the connecting rods being alternately in compression and tension, for the reversal allows the lubricating oil, which is under pressure, to flow freely all over the bearing surfaces; (4) the loads on the main bearings are greatly reduced, the pull of one connecting rod being largely counteracted by the thrust of the adjoining rod; (5) the balance of the engine is excellent, owing to the fact that the centres of gravity of the reciprocating masses working side by side nearly coincide; (6) the engine, owing to its construction and balance, is suitable for working at higher rotating speeds than the ordinary reciprocating engine; (7) the turning effort of a 4-crank Fullagar engine is equal to that of an 8-crank engine working on a four-stroke cycle. Both this point and the previous one are of special importance in connection with the driving of dynamos; (8) the engine occupies a relatively small floor space. The outline general arrangement drawing in Fig. 4 indicates the saving in floor space of a 750 B.H.P. Fullagar engine as compared with a compact four-stroke cycle

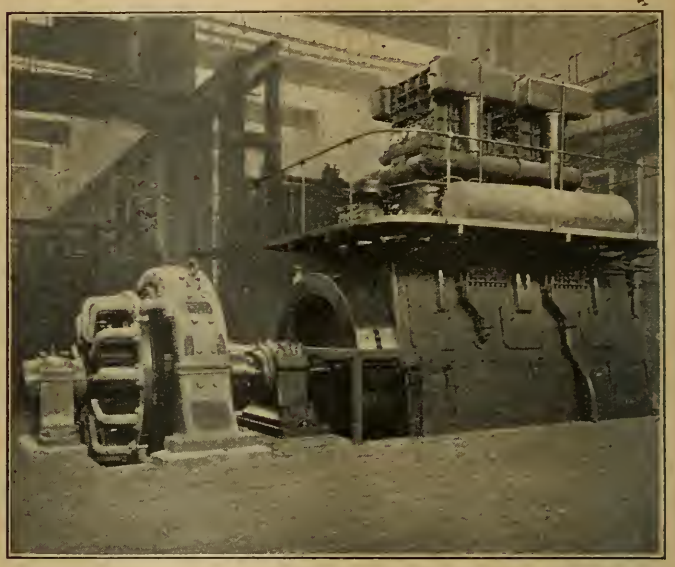

Fig. 3. 750 B.H.P. 4-Crank Fullagar Oil Engine, Running at 250 R.P.M.

Dicsel engine of 500 B.H.P.—*i.e.*, two-thirds of the power of the Fullagar engine. The length of a six-crank Fullagar engine of 1 125 B.H.P. would be only one-third greater than that of the 500 B.H.P. Diesel engine referred to; (9) the total weight and the individual weights of the various parts of this engine are less than those of the standard 500 B.H.P. Willans Diesel engine. The lower weight facilitates handling during transport and erection, and also overhauling; (10) although the Fullagar engine, owing to the opposed piston construction, is decidedly higher than an ordinary Diesel engine, the height required to the crane hook for getting out the pistons is less than is necessary to withdraw the piston of the standard 500 B.H.P. Diesel engine complete with its connecting rod clear of the top of the cylinders. The oblique rods do require more head room, but these can be drawn out when necessary by a light fitment attached to the crab of the crane. The pistons can be readily withdrawn without disturbing any high-pressure joints, and, of course, there are no cylinder covers to be removed.

Fig. 4 shows a four-crank Fullagar oil engine which develops 750 B.H.P. at 250 revs. per min. This engine is coupled to a 500 kW dynamo, and is used for supplying current for power and light in the Rugby Works of the English Electric Company. The engine works on the Diesel system—*i.e.*, the air in the working cylinders is compressed to raise the temperature of the air to about 1 000° F., in order to ignite the fuel oil, which is atomised and blown in by compressed air. A three-stage air compressor driven from the end of the crankshaft supplies the air required for starting the engine and for injecting the oil. The scavenging air is supplied from the chambers in which the upper crossheads work. The crossheads

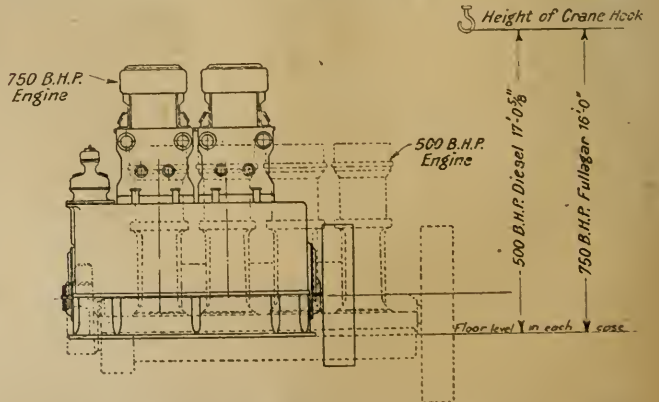

Fig. 4. Comparison of 750 B.H.P. Fullagar 2-cycle and 500 B.H.P. Diesel 4-cycle Engines.

thus act as pistons, the automatic air inlet and delivery valves being contained in the boxes in front of and behind the chambers in question.

Valve Gear.

The valve gear is illustrated in Fig. 5. The only mechanically operated valves are the fuel admission valves, of which there is one

per cylinder. The starting air valves fitted on two of the cylinders are opened by compressed air, these valves being in operation only during the first few revolutions at starting up. All the main bearings, connecting-rod bearings and lower crossheads are forced lubricated. The main pistons, upper crossheads, air compressor and practically all other parts are lubricated by mechanically operated lubricators driven from the camshaft.

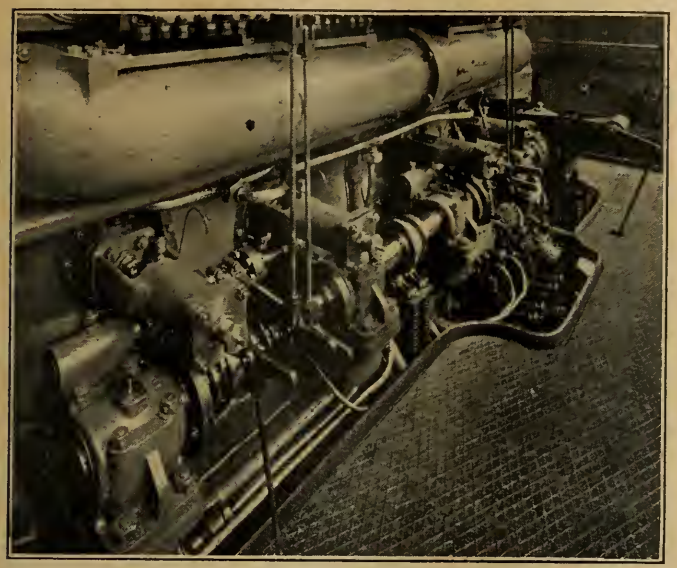

FIG. 5.—VIEW OF VALVE GEAR.

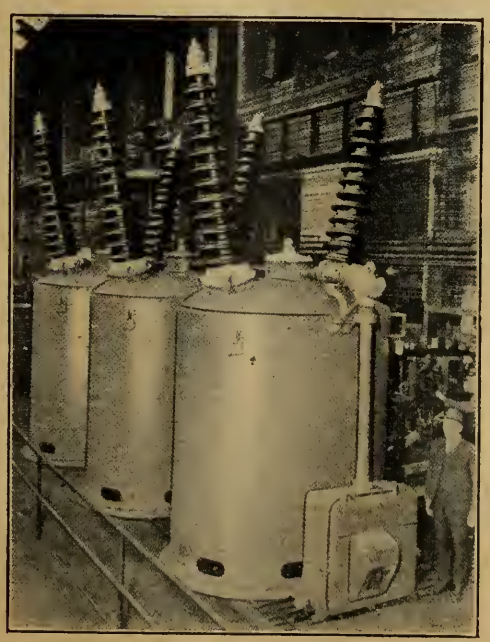
The fuel oil used in the engine is that normally supplied for use in Diesel engines built by this company. It has been demonstrated by extended trials that the fuel economy of the Fullagar engine per B.H.P.-hour is at least equal to that of a Diesel engine having the same size of cylinder.

A Large h.t. Oil Circuit Breaker.

The WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY has just shipped to the Pacific Gas and Electric Company what is believed to be the largest oil circuit breaker yet built. The breakers were built for the 220 000 V Mount Shasta developmnet, and are for use



THE H.T. OIL CIRCUIT BREAKER FOR THE MOUNT SHASTA DEVELOPMENT.

on a 220 000 V system having a solidly earthed neutral. The breaker has stood a 350 kV wet test.

The gross shipping weight of the apparatus, including oil, is 90 000 lb. or 45 tons. The net weight of the unit, erected on foundation, is 75 000 pounds. The breaker requires 2 000 gallons of oil for each pole and its net weight exclusive of oil is 30 000 lb. The height from the ground to the top of the bushing is 17 ft. 6¼ in., and from the ground to the top of the tank is 9 ft. 8⅛ in. The long diameter of the tank is 8 ft., while its short diameter is 5 ft. 8 in.

The "Posterlite."

The poster which tells its story by night as well as by day has obvious advantages over its rivals whose appeal ceases at sundown. In some cases, however, hoardings cannot be illuminated by means of floodlights fixed at a distance, and for these conditions the "Posterlite," a new bracket unit which can be fixed above the top of the surface to be illuminated, has been designed by the BRITISH THOMSON-HOUSTON CO.

This unit consists of a sheet copper trough with silvered glass reflectors bent to correctly designed contours to give a concentrated flat beam. The mouth of the trough has across its length louvres of

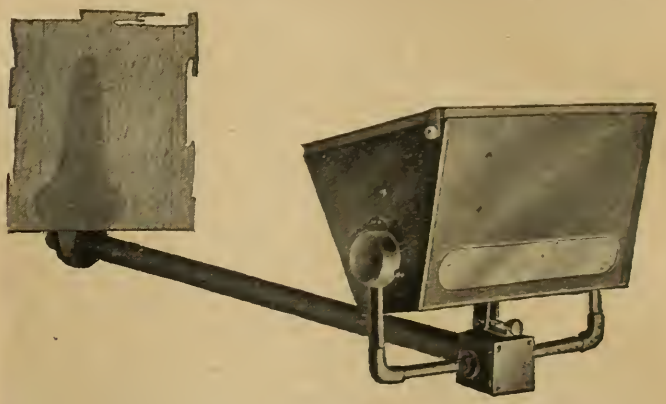


FIG. 1.—B.T.-H. "POSTERLITE" UNIT (PATENT APPLIED FOR) SHOWING BACKPLATE FIXED TO BACK OF HOARDING, WHICH IS 'GHOSTED" IN THE PICTURE.

diffusing glass and metal. These modify and diffuse the light on the upper portion of the hoarding without in any way interfering with the main beam of light which illuminates the lower portion. In this way an even illumination is produced over the entire vertical surface.

Lateral Distribution of Light.

The lateral distribution of light is very wide, allowing the units to be spaced as much as 10 ft. apart. Each unit takes two 250 W projector type Mazda lamps, which can be connected either in series or parallel for use on high or low voltage circuits. "Posterlite" units can be used on all hoardings from 10 to 20 ft. deep. Where hoardings stand alone and have no brightly illuminated surfaces adjacent these units will be found satisfactory for depths up to 25 ft. For average conditions, units spaced 10 ft apart will give good results.

The Backplate.

The backplate is so designed that it may be attached either to the front or back of the hoarding, the tube being secured in position

FIG. 2.—SWAN VESTA POSTER, STRAND, LIGHTED BY MEANS OF TWO "POSTERLITE" UNITS.

by two taper pins passing through the boss in the backplate. An entry (tapped 1 in. conduit) is provided through which the supply can be brought into the bracket. An insulated connector is provided in the head of the bracket to which connection can be easily made, the unit being sent out with the holder wired to this point.

Retirement of Sir William Noble.

On Wednesday Sir William Noble, Engineer-in-Chief at the G.P.O., retired, after 45 years in the postal service. Beginning his official career in 1877 as a telegraphist in Aberdeen, William Noble was not content to be a manipulator all his life. He devoted his spare time to acquiring a proficient knowledge of Pitman's shorthand and to studying English, mathematics, the principles of electricity and magnetism, and other kindred sciences. He won medals in both the ordinary and honours grades in the City and Guilds examinations in telegraphy and telephony and was appointed lecturer in those subjects at Gordon's College, Aberdeen. His classes were remarkably successful. In one year three of the five medals offered went to Aberdeen. Later in his career Sir William was appointed examiner in telegraphy by the Institute of the City and Guilds of London and held the post for some ten years.

His success attracted attention throughout the service and in 1893, after a short training in routine procedure in the Engineering Department in Edinburgh, he was appointed engineer-in-charge of the Aberdeen Section. Four years later he was promoted to a first-class engineership at Headquarters, and in 1900 he was appointed second-class technical officer. The Post Office had just undertaken the task of installing a telephone system in London, and in 1901 Mr. Noble was selected to act as assistant superintending engineer in the newly created Central Metropolitan District. He had a large share in the work of the "telephoning of London," the magnitude of which is not generally appreciated.

Steady Promotion.

In 1905 he was recalled to headquarters as first-class staff engineer and placed in charge of the Telegraph Section, which included wireless telegraphs in those days, the operations of radio work not then having reached the magnitude and importance now attained. The comparative seclusion of a section at headquarters did not act as a sedative to his energy. It was during this period that central battery working was introduced. He also vigorously promoted the development of machine sending and printing telegraphy. In 1907 he returned to the London District as superintending engineer of the Central Area. After improving and consolidating the organisation of that district he recommended the amalgamation of the three London districts into one, in order to reduce the overhead charges and to simplify the transfer of the National Telephone Company's system and staff to State control. The recommendation was not accepted at the time, but after the transfer two districts were formed out of three and eventually his original proposals were adopted and a single London Engineering District covering the entire area came into being.

During the years in which he held the post of superintending engineer, Sir William was called upon to serve on many departmental committees. For five years he was chairman of the Factory Works Committee. He, in conjunction with Mr. Sinnott, was responsible for the present system of joint examination which deals with the examination and repair of all apparatus used by the department. Prior to the transfer of the National Telephone Company he was appointed engineering representative on the Staff Transfer Committee, set up for the purpose of grading into the existing Post Office classes the members of the national company's staff.

Services Recognised.

In 1902 Sir William was appointed assistant engineer-in-chief The engineering staff by the transfer of the company had increased threefold, and the new assistant immediately set himself to organise the combined staffs into a homogeneous whole. The next few years were years of great activity. New exchanges were installed everywhere, underground schemes were provided in almost every industrial centre, obsolete lines and plant had to be recovered, and a vast network of main underground trunks was planned and commenced. But for the war the telephone service in this country might by this time have been equal to the best in the world. For his services in connection with the work done by the Signals, R.E., during the war, which was largely Post Office, the King of the Belgians created him a Chevalier de l'Ordre de la Couronne for "constant and generous help" during the war.

In 1919 Sir William Slingo retired and was succeeded by Mr. Noble. One of the most remarkable tributes to Sir William's success during his tenure of office has been the fact that the telephone industry has been entirely free from disturbance or dislocation due to trade disputes. His services were recognised by the King in 1920 by the conferment of knighthood, an honour which came to him earlier than to any of his predecessors in office.

In the course of his career Sir William has visited many European countries on telegraph and telephone business and has reported on the methods and apparatus used by Continental administrations. He is president of the Institution of Post Office Electrical Engineers and is also a Member of Council of the Institution of Electrical Engineers, and last year read a paper before that body on "The Long Distance Telephone System of the United Kingdom" for which he was awarded the Fahie Premium. He is probably the best known Scot in London to-day, outside the ranks of the Parliamentarians; and it is not at all unlikely that even this exception may be omitted in the near future.

Barton Power Station.

Mr. S. L. Pearce, chief engineer and manager to Manchester Electricity Department, gave a description of the new Barton power station and other electrical developments in south-east Lancashire to the Manchester Rotary Club last week. The designs of the station, he said, had been most carefully thought out. Thanks to the generosity of the Manchester Electricity Committee, he had been enabled to see some of the large plants not only in other parts of this country but also on the Continent and in the United States, and he assured them that the best features which could be embodied in a modern power station would find a place at Barton; Every factor they knew of which made for efficiency had been introduced. They were installing some 120 000 h.p. of the plant in three large units of, approximately, 40 000 h.p. each. The capital outlay on and incidental to the station had been very heavy, totalling about 3½ million pounds sterling—on the station about £2 400 000, on the transmission lines £630 000, and on distributing stations about £230 000 to £240 000. Roughly speaking, the cost of every kW installed at Barton, as compared with what the cost would be in 1915 and 1916, was about 2½ times as large. Some of them might ask whether the Corporation was justified in embarking upon the scheme at such a time of high prices. He thought there could be only one answer. Manchester was a most important growing industrial centre, electricity entered into the life of its people at every point and stage, it could not buy its electricity elsewhere, and it was necessary to make provision to-day for the needs which would arise when trade improved. The effect of the high capital outlay could be minimised to a great extent. The station had been designed to reduce to the lowest possible basis the coal bill and labour charges and to ensure a high degree of reliability. The plant must be run for the maximum number of hours possible. It must become what the Americans called a "base load" station. The ideal station would, of course, run at full load for 8 760 hours per annum, giving 100 per cent. load factor. This was impossible, of course, but the aim should be to get as near that figure as practicable. There was no reason why 60 per cent., and possibly more, should not be attained. At Stuart Street it was about 40 per cent. At Barton, as compared with Stuart Street, the coal consumption would be reduced by at least 30 per cent.

Tariff Reduction.

Referring, lastly, to the subject of prices, Mr. Pearce said that the average prices obtained in Manchester during the last financial year did not compare unfavourably with those of other large undertakings, such as those of Liverpool, Glasgow and Birmingham. They were lower in all respects, excepting that of lighting in Glasgow. Still, they recognised that prices would have to come down, and a start was to be made in June. He hoped that as Barton came into operation and energy became available the Electricity Department would adopt a more forward sales policy with regard to the supply of electrical apparatus for household use. Last year's results, notwithstanding the industrial slump, were better than might have been expected. Although sales fell to the extent of 42 million units there was a substantial sum on the right side.

In the course of some discussion the opinion was expressed by two speakers that Manchester was the most backward city in the north in the use of electricity for cooking purposes, and that the cost of electricity might be considerably reduced. One speaker said he was obtaining it in Grimsby at half the price he had to pay in Manchester, and that in a new factory his firm was using oil in place of electricity.

The Institute of Physics.

At the Annual Meeting of the Institute of Physics, held on May 23, the following officers and board were elected to serve for the year beginning October 1, 1922. *President*—Sir J. J. Thomson. *Past-President*—Sir R. T. Glazebrook. *Vice-Presidents*—Sir Charles Parsons, Prof. W. Eccles, Prof. C. H. Lees, Mr. C. C. Paterson. *Non-Official Members of Board*—Dr. R. S. Clay, Prof. C. I. Fortescue, Prof. A. Gray, Major E. C. Henrici, Sir J. E. Petavel, Dr. E. H. Rayner, Sir Napier Shaw, Mr. R. S. Whipple. *Representatives of Participating Societies*—Physical Society, Mr. C. E. S. Phillips, Mr. F. E. Smith; Faraday Society, Mr. W. R. Cooper; Optical Society, Mr. John Guild; Rontgen Society, Dr. G. W. C. Kaye; Royal Microscopical Society, Mr. J. E. Barnard.

The annual report stated that there were 408 members of the Institute at the end of the year, of whom 258 were fellows. The Institute is watching the possibility of establishing a central library for physics, although the financial difficulties in the way of its realisation are stated to be considerable.

In the course of his presidental address Sir J. J. Thomson, after dealing with the project to establish a Journal of Scientific Instruments, spoke of the present depression in industry, but he made the reassuring statement that out of 67 students who graduated with distinction in physics and chemistry in 1921, 40 had obtained suitable positions, while 14 were doing research work. He hoped that the series of lectures on Physics in Industry which had been established would act to some extent as "Refresher Courses."

Speaking of the difficulties which the Safeguarding of Industries Act had in many instances placed in the way of research, he characterised research as a "key industry," and he hoped that the Government would put every facility in the way of research workers being able to obtain without delay the apparatus they required.

Railway Companies' Electric Power.

The South-Eastern and Chatham Railway Companies' and West Kent Electric Company's Schemes have been before the Electricity Commissioners (Sir John Snell and Sir Harry Haward) during the past three days at an inquiry at the Middlesex Guildhall, Westminster.

Mr. W. D. Clode, K.C. (for the S.E. Railway Company, the L.C. and D. Railway Company and the South-Eastern and Chatham Railways Managing Committee), opening the case for his clients, said it was proposed to erect a station at Angerstein's Wharf, Charlton, 20 acres of which were available for the generating station. The energy would be supplied to a sub-station at Lewisham, about 3½ miles away. The railways he represented were included in the 1921 Railways Act in a group which also included the South-Western and the Brighton Companies. The L. and S.W. Company were generating their own energy and the L.B. and S.C. Company were taking a bulk supply from the London Electric Supply Corporation. Both were using a.c. at 25 cycles. The Companies Act of 1903 scheduled six sites which his companies might use for generating stations, but these did not include Angerstein's wharf. As soon as the cloud caused by the war began to pass away, their friends in the neighbourhood around London began to jog their memories with regard to their intention to electrify their lines, and several local authorities decided to support the application of the railway companies for sanction to the electrification of the North Kent and loop lines. A deputation waited upon the Chairman of the Companies' Committee on May 23, and impressed the urgency of the matter upon him. The Managing Committee applied to the Advisory Committee under the Trade Facilities Act asking if the necessary capital could be guaranteed by the Treasury, and the Advisory Committee agreed that the capital could be raised on much better terms if a guarantee were given.

Lines to be Electrified.

The railway lines proposed to be electrified in the first instance were the North Kent and Greenwich line, the Bexley Heath line, the Dartford loop line, the main line down to Orpington, the Bromley North Branch line, the Mid-Kent and Hayes line, the main line to Bickley and Orpington, the Crystal Palace and Greenwich Park line and the Catford loop line. These amounted to 94 route miles (210 single line miles). Ultimately the electrification of 241 route (640 single line) miles was contemplated. His clients might be able to cater for the Brighton Railway when the present agreement of the latter for bulk supply ran out. The Advisory Committee found the proposals technically sound, and referred the matter to the Minister of Transport, who appointed a committee of experts, presided over by Sir Philip Nash, and including Sir Alex. Kennedy Sir Philip Dawson and Mr. Stevens, who approved proposals to erect the generating station at Angerstein's Wharf. The estimate of the total cost was from 6 to 6½ millions. The Treasury were satisfied that the estimate was reasonable, and the Government had intimated that they were prepared to give a guarantee for the payment of principal and interest, provided a satisfactory agreement could be arranged. The generating station would be erected by the Construction Company, which was being formed with a capital of £10 000 and borrowing powers of 6½ millions, and would be leased to the Managing Committee, who would pay an annual rent to cover the interest on the debenture (which would be the form of the loan from the Bank of England) and a sum of not less than £95 000 per annum for redemption, taxes and expenditure in connection with the formation of the Construction Company. The maximum period during which the Treasury guaranteed the payment of principal and interest was four years. The provisional agreements would be put before the Minister of Transport, and an application would be made for an order under the 1903 Railways Electrification Act.

Necessity for New Station.

Counsel agreed with Sir John Snell that the present inquiry might make the Minister of Transport's inquiry unnecessary. The companies could not afford to wait for other supplies to be provided, as their opportunity for getting the Treasury guarantee would be gone by November 22 next. The West Kent Company had not yet got the Commissioners' consent to their station, and he understood the West Kent Company's proposal was strongly objected to. Their negotiations with the Advisory Committee and the agreements were based on the completion of the station and the line in three years. In the agreement between the Construction Company and the Treasury it was provided that the Railway Companies should have the option of taking over the station, on terms specified, at June, 1927, or any subsequent five years until 1942, and the Treasury guaranteed the payment of the principal and interest of the loan. The plant was to be wholly of British manufacture. They had had communications from the West Kent Company, which took current in bulk from the South Metropolitan Electric Light and Power Company. The West Kent Company was a small company with a large debt and was not now in a position to raise a large sum of money. It proposed to erect a station at Belvedere, and the proposal was opposed by London County Council. He intimated that he proposed to call Mr. Cosmo Bonsor, Chairman of the South-Eastern Company and of the Managing Committee, to deal with the financial proposals, but he suggested that he should not give full technical details showing the cost of generation until the West Kent Company had given evidence on their scheme. After which the figures as to cost of energy for both schemes should be put in simultaneously.

Mr. W. E. Tyldesley Jones, K.C. (for the West Kent Company), said this procedure was ridiculous. It was essential that they should know first what the railway companies offered.

Sir John Snell ruled that the railway companies must call evidence to prove the cost at which they could supply energy. They would have the last word after other parties had been heard.

Evidence for Companies.

Mr. H. O. Cosmo Bonsor confirmed counsel's statements as to the necessity for the electrification, and said it was only after the Trade Facilities Act was passed that they were in a position to go to the Treasury. The Advisory Committee said this scheme was one of the best put before them. The arrangement with the Treasury was that the Construction Company would create a debenture which would be lodged at the Bank of England with a Treasury minute attached. They would borrow the money as they wanted it. They could get their money in the cheapest market, but they could if they wished get their money at the current bank rate, which was 4 per cent. at present. The Treasury Bill rate was only 2¼ or 2½, and he could get money at a slight fraction over that. Therefore he could get his money cheaper than anybody else.

Cross-examined by Mr. Tyldesley Jones, witness said he did not think Sir Philip Nash's Committee considered the questions of erecting a power station and of purchasing electricity in bulk.

Answering questions by Commissioners, Mr. Bonsor said the practice of the Bank of England was to lend money for three months, after which it had to be repaid or the loan renewed. In this case they had gone out of their way to lend it for three years. At the end of that time they would probably only renew for three months. He still had no intrinsic objection to taking current from an outside supply if the price were as cheap and the guarantees were as good.

To Mr. W. S. Kennedy (for the London Electricity Joint Committee) witness said when the proposed Joint Electricity Authority was in working order it might be in the public interest for the railway companies' station to be taken over for general supply.

Replying to Sir Harry Haward, he admitted that he would only get the money cheaply so long as the Bank rate was low, but he always borrowed at less than the Bank rate. At the end of the three years the temporary loan would be turned into a permanent loan. Before that time the Southern Group would have taken over the whole thing. The annual amount for redemption, taxes, etc., would be nearer £110 000 than £95 000. The Treasury had made no requirements with regard to turning the temporary loan into a permanent one. There would have to be a sinking fund set up after the three years to liquidate the indebtedness in 22 years.

Questioned by Sir John Snell, he said he thought the only discussions between his companies and the Brighton company were as to whether they were to link up with the London Electric Supply Corporation's station at Deptford. As to the desirability of getting part of the supply for the Southern Group from Wimbledon, part from Deptford and part from Angerstein's Wharf, witness said they might all get it from Angerstein's Wharf when the station was developed.

Mr. C. P. Sparks then gave technical evidence.

Branch Factories in Canada.

In a letter to "The Times," based on the recent correspondence on "What can we do with our Sons," Mr. Frank Carrel, member of the Legislative Council of the Province of Quebec, and proprietor of the "Quebec Telegraph," who is now in England, urges British manufacturers to take more interest in the establishment of branch factories in Canada. During the last 25 years some 700 American and foreign factories have been established and are doing well. New labour-saving machinery is being rapidly introduced. Such modernism does not (he states), as Labour representatives say, cut down general labour, but increases production, at a less cost, with the same capital and plant. While it is perhaps, true that Canada is not ripe for every class of such branch factories, there is no doubt that there is room for a large number of them, particularly in a province like Quebec, where, within the next 25 years, the greatest electrical development of any part of the world is about to take place. In this short period of time millions of pounds will be invested in developing the immense waterfalls to generate electricity for railways and factories. This will again reduce manufacturing costs.

Speaking on this subject, a Government official over here, Mr. Carrel states, enumerated all kinds of reasons why British manufacturers did not go to Canada, among them the difference in electrical apparatus or appliances. This, he says, may be true, but asks, would it not be in order to adopt the American product to fill the branch factory with orders?

"From existing facts, staring us in the face," he concluded, "it seems to me that all offices engaged in preserving British trade should be most optimistic relative to the establishing of branch factories, particularly in Canada, where, all things being equal, they would be assured of a thriving business and protection of capital in a growing country, whose population will soon rival the British Isles."

Opening up Europe.

By SIR ERNEST J. P. BENN.

THE ILLIMITABLE POSSIBILITIES OF EUROPE as a market are at long last beginning to attract the serious attention of commercial men. The continent of Europe, the centre of civilisation, with 1 000 000 000 human souls, has, from a trade point of view, for nearly eight years been dormant. From a business point of view there never were such opportunities and openings as now present themselves in Europe. The people have learnt that Peace Treaties and Supreme Councils cannot provide food and houses and clothing and all the little luxuries on which they have set their hearts; the eyes of the world are coming round to the business man, and the business man will undoubtedly show himself worthy of the opportunities that now confront him. Mr. Lloyd George, on his return from Genoa, told us that all the peoples were yearning to get back to business, and that they looked to England to give them a lead.

Potential Trade Openings.

Apart from these general considerations, a study of the problems in detail and an examination of the situation in each of the thirty sovereign States which now compose the Continent of Europe lead to the same conclusion. Everywhere one finds potential trade openings of unprecedented magnitude, and everywhere one also finds that the eyes of the populace are turned towards England in this connection. Take as an example the new State of Poland, a vast area almost as large as the United Kingdom. Less than four years ago the new Poland was partly German, partly Russian and partly Austrian, and it is now a mighty new nation anxious to build up a great commerce on its own. This new sense of independence which fills its blood makes it turn to new quarters in commercial matters and seek in England and in France for trade connections. By transferring trading interests in this way a new independence is established on a more solid and a firmer basis than a mere Treaty of Peace. Similar considerations and similar circumstances are found wherever one turns.

Englishman's Hazy Idea of Europe.

The average Englishman knows something of Paris and Brussels, he is vaguely aware of the location of Berlin, and if he is a young man he is closely and painfully acquainted with the geology of Flanders; but, apart from that, our ignorance of Europe as a whole is little short of appalling. Most people are surprised when they are told that Warsaw is a town which rivals Manchester in importance and astonished when they find its fine, broad streets swarming with hundreds of thousands of clerks and messengers, and its postal and transport and telegraph services buzzing and humming with an activity which is only equalled by our own. Yet Warsaw is one of thirty towns within a couple of days' journey of London all of equal commercial importance. Very few people know that there is a daily train which runs from Ostend to Constantinople, or that you can get into a train de luxe at Riga and run straight through to Madrid any day of the week that suits you. There is hardly a corner of Europe which is not to-day oozing with business opportunities; all along the thousands of miles of Soviet Russian frontier are squatted eager traders, profiteers if you like, engaged in illicit business with the unfortunate Russians, and this commerce has assumed such vast importance that a big international exhibition is to be held this year at Reval.

The Americans have, as might be expected, not been slow to realise these possibilities, and Europe is to-day literally swarming with visitors from the United States. The farther east one goes the more one seems to meet these enterprising people Constantinople is full of them, and every town on the way has its quota.

Difficulties *v.* Opportunities.

There are difficulties—of course there are difficulties—grave difficulties, but the chief difficulty is surely that the manufacturer and the trader of our generation has been so spoilt, so spoon-fed, so cared for and looked after, that he cannot work up the energy to attempt any business except that which is positively smooth, easy and certain. There is first of all the question of currency. It is far too commonly supposed that a fluctuating currency or a depreciated currency is a bar to business. It is an inconvenient circumstance, but nothing more. The risks of fluctuation can be covered by the purchase of currency at any moment in any market. The way in which the peoples of Europe have accommodated themselves to the instability of currency conditions is one of the marvels of the age. If the people of Austria can still live in comfort with a money which has depreciated to a ten-thousandth part of its former value, surely the British merchant is not incapable of accommodating himself to similar conditions. All these difficulties do not really count when measured by the opportunities which exist. If the English trader still insists on having his business made fool-proof before he will proceed, then others will supply the needs of Europe; but, if that fine, commercial spirit, which was at one time England's pride would to-day arouse itself, both England and Europe might be very much better off in the next few years.

A European Trade Paper.

These are the considerations which have led BENN BROTHERS, LTD., to take the bold step of establishing a commercial weekly paper in the very centre of Europe. The "European Commercial," which will make its appearance from Vienna in the first week in September, will have a dual mission. On the one hand, it will set itself to inform the merchants of England and America of the actual conditions in the various States of Europe. On the other hand, it will be acclaimed throughout commercial circles in Europe as a link between them and England and will enable them to do the thing which to-day they most desire—to get into touch with English merchants, manufacturers and financial houses, and open up business negotiations. The "European Commercial" comes upon the scene at the moment when Europe is ripe for a commercial revival; the business men of all countries now realise that they must get together and get busy if civilisation is to be saved, and the "European Commercial" is the first big important step in that direction.

The Palestine Water Power Concession.

THE New York correspondent of *The Times* gives some particulars of the CONCESSION OBTAINED BY M. P. M. RUTENBERG, a Russian engineer, for the exclusive development of the water power resources of Palestine and for the general supply of electricity. It is unfortunate that we should have to go to New York for information on a subject of such interest to British engineers, but it is not the first time in recent years that we have had to rely on foreign sources for our knowledge of British and Imperial affairs.

It appears that M. Rutenberg is at present in New York in order to raise capital for the first part of his project, which includes the erection of a hydro-electric station on the Jordan below Lake Tiberias, and the construction of three power houses at Haifa, Jaffa and Jerusalem. These three stations will be equipped with Diesel engine sets, and for the whole project about one million pounds will be required. The terms of the concession, according to M. Rutenberg, provide for the retention by the Palestine Government of a large measure of control—both financial and technical—over the company, which will be formed to exploit the concession. The financial organisation of the company, and its methods of generation and supply, must be approved by the Palestine Government. Dividends up to 10 per cent. will be retained by the company, but from 10 to 15 per cent. they will be divided equally between the company and its consumers in the shape of a reduction of rates. All profits above 15 per cent. will be paid to the Government of Palestine.

In the course of an interview M. Rutenberg said he believed that when the country was at peace sufficient electrical energy would be available, and industries at once could be established to provide work for large numbers of people. Both Jewish and Arab labour could be employed in the construction and operation of the power-houses. The Palestine Government had arranged to grant loans, which the company would guarantee, to municipalities in Palestine, to enable them to participate in the scheme as shareholders. A loan to the municipality of Jaffa had already been arranged. In addition to £100 000 each subscribed by the London Economic Board, Baron Edmond de Rothschild, and the Palestine Development Council, £200 000 had been subscribed by the Jewish Colonial Trust of London. No orders for machinery and materials had been placed, and none would be given until the £1 000 000 had been obtained. M. Rutenberg stated that he had written to the Colonial Office stating that he was willing to pay British firms up to 10 per cent. more than was asked by firms of other countries.

In a further interview M. Rutenberg stated that all consumers (Arab and Jewish) would enjoy equal privileges, and municipalities would be entitled to buy electricity in bulk and have their own distributing systems; with Jaffa and Jerusalem municipal authorities negotiations have been opened and they will both probably participate in the scheme. The directors will be elected by the shareholders according to the amount of capital invested.

Orders have been placed in Germany for two Diesel engines and electric generators for the Jaffa station, which will be the first to be erected. The cost of this plant is given as £15 954, but cables and wires of the value of £2 743 have been ordered from Great Britain. The reason for placing the orders for the generating plant in Germany is stated to be due to the fact that British prices were over 120 per cent. above those of the accepted tender. The German quotation for a 500 H.P. set was £5 235 c.i.f. Palestine, and the lowest British tender was £11 610 f.o.b. British port.

Crime Detection by Wireless.

Wireless telephony is being USED EXTENSIVELY IN NEW YORK AND CHICAGO for the detection of crime and the capture of criminals. Both cities possess research departments for studying the adaptation of wireless to police work. The police have wireless distributing stations, from which news of crimes is flashed over a wide area every day, and they also possess high-power motor-cars equipped with receiving and transmitting sets, enabling conversations with police headquarters to be kept up even when the cars are travelling at fifty miles an hour. As soon as sufficient equipment can be manufactured every Chicago policeman will, it is stated, be equipped with a miniature receiving set. Wireless receiving sets have been ordered for each of the fifty police stations of Chicago.

The Chief Commissioner of the London Metropolitan Police is also keeping in touch with wireless telephone developments. For the past three months experiments have been made at Scotland Yard to test the use of wireless as an aid to directing the movement of officers in search of criminals. The Chief Engineer of the Yard is in charge of the experiments.

Brighton's Electricity.

In an address at the weekly luncheon of the Brighton and Hove Rotary Club last week Mr. JOHN CHRISTIE, electrical engineer to Brighton Corporation, traced the history of the Brighton electricity works. He mentioned that when an electricity company began operations in 1882, before the Corporation had obtained a Provisional Order, there were 200 consumers and the approximate cost was 2s. per unit. The goodwill of the company was purchased for £5 000 the Corporation Order (obtained in 1883) was put into force in 1890, and the first section of the North Road works opened in September, 1891. In 1900 an Act authorised the new power station at Southwick, which was opened in June, 1906. In 1892 the number of consumers was 213, the price 7d. per unit, the capital expenditure £55 000, and the total revenue £4 680, while in 1921 consumers numbered 8 441, the units output (at 8d. per unit) was 11 261 408, the capital expenditure £897 787, and the total revenue £202 117. During that period £575 000, or 64 per cent. of the total capital, had been set aside for repayment of loans, £32 492 (including £8 000 of this year's surplus) had been applied to relief of rates, and the reserve fund stood at £30 000.

With regard to the policy of finance he was up against his Council and Committee, because he held—as a ratepayer and not as an official—that the consumers were really being super-taxed by paying higher prices than they should pay for the benefit of a large proportion who were non-consumers of electricity. Would not they as business men rather have a 10 per cent. reduction on their electricity account than a paltry 3d. off their rates ? The Gas Company were the biggest ratepayers, and their keenest competitors but they did nothing in the way of helping the electricity undertaking to get new business. The Corporation ran the undertaking for the benefit of their users and with the object of supplying at the lowest possible rates, and when they had a reasonable surplus it should be put to a reserve fund and not to the relief of the rates. The plant would probably outlive the period of the loan, but it did not pay to utilise plant all that time. It paid them to scrap it and use modern machinery, so that they could generate cheaply. Ultimately all ratepayers would be users of electricity, and they therefore wanted a substantial surplus available. They must get rid of obsolete plant, and, having secured a system of oil fuel firing and suction coal-handling, they hoped to be able to effect a good deal of labour saving, and at the same time to ensure a supply of electricity for the trams, public lighting, and various industries.

Brighton's Front was the finest in the world, but he thought the lighting should be brought up to date, and was confident that if the Corporation would see their way to substitute for the present lights a modern type of lantern at a comparatively moderate cost the lighting could be greatly improved. Their shops were the finest in the country, but it was pitiful to see the lack of enterprise on the part of shopkeepers after dark. In the early evening the shop windows were brilliantly lighted, but the tradespeople appeared to give little consideration to the scientific lighting of their premises after the closing hour, although it could be easily and simply arranged.

Efficiency Exhibition at Birmingham.

The Lord Mayor of Birmingham opened on Thursday last an industrial and commercial efficiency exhibition at Bingley Hall, Birmingham, which will remain open until to-morrow (Saturday). The venture has attracted a good deal of attention, for it is recognised that if firms are to make headway when trade revives business must be run efficiently and economically on taking advantage of scientific and modern methods.

In addition to the system, shown by MANIFOLDIA, LTD., for ensuring perfected supervision and record keeping of electrical installations, of which we propose to give a fuller description next week, there are a few other exhibits of interest to the electrical industry. In a comprehensive display of goods, by the BRITISH INSTITUTE OF INDUSTRIAL ART, the object of which is to show the importance of a close alliance of art with industry, there are some choice electric light pendants, lamps, etc. ; and the RELAY AUTOMATIC TELEPHONE CO. show a complete installation for an interdepartmental automatic telephone system, giving facilities for connection to fifty telephones. It comprises the automatic switchboard, power board, two sets of 24 V batteries and telephone instruments all connected up for use. The functions of the power board and accumulators are to store and distribute the electric energy for working the switchboard ; the power used for this purpose is supplied from a 24 V battery of accumulators, which can be charged from the existing electric light system, either direct or through a motor generator. A variety of scientific instruments are exhibited by the FOSTER INSTRUMENT COMPANY, including thermometers of the electrical resistance type, in fixed indicating form ; and Delco-Light plants are displayed by F. S. BENNETT, LTD., with generator direct connected to engine for 32 V or 110 V service.

The ZENITH MANUFACTURING CO. have just issued Leaflet Z.M.55, giving prices and particulars of their new range of " Zenite " vitreous embedded resistance units. Since this firm started the manufacture of these units nearly a year ago, they have had frequent demands for them in similar sizes to those hitherto imported from abroad, and are able to meet all requirements.

Wireless Developments at Trafford Park.

A practical demonstration of the possibilities of the radio receiving sets which will be manufactured at the METROPOLITAN-VICKERS COMPANY'S Works at Trafford Park, was given to a representative of THE ELECTRICIAN a few days ago. When the arrangements for broad-casting are completed and the formal permission of the Post Office is given the company will proceed to manufacture three types of receiving apparatus.

The simplest and cheapest type comprises a small crystal detector fitted with an ordinary telephone head-piece. It is expected that this will sell well at about £5 to £10 and will pick up messages roughly over a range of 25 to 40 miles. The next size, which is a valve set, will have a range of 50 to 70 miles and will probably cost about £20. The largest set will cost about £75 and will have a range of at least 150 miles and will probably pick up all over the British Isles. This set is extremely well finished and resembles a cabinet gramophone in appearance. It contains four thermionic valves.

The manipulation of these sets is very simple. The pressing of a button and turning of a small control handle through 180° are all that is necessary, the latter operation being to tune the set to pick up a particular wave length. Slight detuning diminishes the sound without altering the pitch.

A demonstration was given in the company's research department, waves being sent on an improvised transmitting apparatus from one part of the building to another ; the largest receiving set was employed, no aerial being necessary. Songs, violin solos, etc., were reproduced faithfully on the gramophone, and ordinary speech was rendered quite naturally.

An Electric Scaling Hammer.

Representatives of shipowning and ship repairing firms in South Wales witnessed at the Mount Stuart Dry Dock, Cardiff, last week the first demonstration in the Principality of a new electrical labour-saving tool. This is known as the Sandblom electric scaling hammer and rust remover, placed on the market by the ELECTRIC SCALING HAMMERS, LTD., London, and the demonstration was given by the International Paint Compositions, Ltd. The Sandblom hammer is practically a spindle making about 1 200 revs. per min. equipped with a number of short chains with hammer heads at their free ends. The number of chains varies from two to eight, according to the class of work to be done. The driving power is supplied by a small electric motor of such light weight that it can be conveniently held by the workman operating it. When the motor is started the chains are thrown outward by centrifugal force and the revolving spindle is held parallel to the work so that the hammer heads come into contact with the surface to be scaled. The hammer strikes 10 000 blows per minute, and actual tests made at Copenhagen are stated to have demonstrated that the machine does the work of from 10 to 25 men with hand hammers. The current consumption of the hammer is 330 W, and with current at 1½d. per unit the cost is therefore only ½d. per hour. Hand and pneumatic scaling have, it is stated, been supplanted by electric scaling in Norway and Sweden, for not only are ships' plates scaled electrically at a much more rapid rate, but they are left with an absolutely smooth surface, the small hammer heads entering all the badly corroded indentations and cavities and removing from them thoroughly all the smallest particles of rust without weakening the surface. The demonstration on Wednesday was watched with great interest by the assembly, although the apparatus could not be shown to its best advantage in consequence of the fact that a restricted supply of current did not allow the spindle to revolve at more than 90 revs. per min. However, large portions of thick scale were quickly and easily removed. The machine, which is so portable that it may be employed as part of a ship's equipment for chipping and scaling decks and holds, is not yet in use in this country, but the Admiralty is considering its adoption.

Radmolite.

Makers of electric cooking and heating apparatus who use refractories of various kinds for supporting the heating elements will be interested in Radmolite, a material which the MOLER FIREPROOF BRICK AND PARTITION CO. have now placed on the market. Mr. B. P. Deane, the general manager of the company, claims that this material offers marked advantages over ordinary fireclay and steatite formers for heating elements. Radmolite is largely composed of diatomaceous earth and is remarkably efficient as a thermal insulator. When made up into a firebar it absorbs heat at such a low rate that the element springs into life almost as soon as it is switched on, and with fires which rely on a high temperature element for their popularity this feature is of immense importance. With ordinary fireclay a considerable time elapses before the element attains its maximum temperature, because fireclay absorbs heat at a much higher rate than Radmolite. Recent tests by the National Physical Laboratory indicate that the new material, which can be supplied in moulded form in any of the shapes now common to electric fires employing a fireclay bar will greatly increase the efficiency of electric cooking and heating apparatus, and it also scores heavily over fireclay in the matter of weight, being at least half that of any firebar of similar volume. Lionel Robinson and Co. have been appointed selling agents for this material.

D

Legal Intelligence.

Electricity Commissioners' Powers.

On Friday last a Divisional Court (the Lord Chief Justice, Greer and Acton, JJ.) heard an *ex parte* application by Mr. Ross-Brown, K.C., for a rule *nisi* for a mandamus directed to the Electricity Commissioners requiring them to show cause why they should not hear and determine, according to law, an application by Ealing Corporation, as the authorised suppliers of electricity for the Borough, for leave to enter into an agreement with Hammersmith (London) Borough Council for a supply of electricity. He also asked for a rule for *certiorari* to bring up to the Court to be quashed an order made by the Commissioners refusing them leave to proceed with the agreement which had been provisionally drafted. Counsel said that his ground of application was that the Commissioners, in arriving at their decision, were influenced by extraneous and irrelevant matters, and therefore their assent to the agreement which they could give under Sec. 19 of the Electricity Supply Act 1919 was not properly or judicially exercised. By the Act of 1919 the Commissioners were appointed to regulate and supervise the supply of electricity. From an affidavit of the Town Clerk of Ealing, counsel said it appeared the load on that Corporation's station was up to 75 per cent. of its full capacity and the safety margin had been reached. If during the coming winter there continued to be an increase of consumers the supply capacity would be overtaxed. In the meantime an arrangement had been made with Hammersmith for a bulk supply to augment that of the Ealing District. The terms for this supply in bulk were more favourable than those offered by the Metropolitan Electricity Supply Co. The provisional agreement was put before the Electricity Commissioners, who were told that Hammersmith Borough Council were quite willing to stand by their bargain. The Commissioners, however, refused to allow the agreement, even though the combination of the two boroughs in the supply of electricity would have made a great financial difference to Ealing. Counsel argued that the Commissioners, in considering the merits of the two proposals (one from Ealing and the other from the Metropolitan Electric Supply Co.), went beyond the jurisdiction given them by the Act of 1919, and that if a satisfactory agreement was put before them the Commissioners should accept it.

In reply to the Lord Chief Justice, counsel said he submitted that the Commissioners were dealing with extraneous and irrelevant matters and they went beyond the discretion vested in them if they went into the question whether a supply should not be supplied by another authority.

The Lord Chief Justice said it looked as if the Commissioners had made enquiries into the proposed arrangements and into other matters bearing upon them, and on the whole had come to the conclusion that, although there might be slight financial benefit, it was more than counterbalanced by other objections. "What is it you are persisting should be done?" he asked. "What is the rule you are asking for—that the Commissioners shall approve?"

"Not necessarily," replied Mr. Ross-Brown, "but that they shall consider the application apart from the consideration of the relative advantages of rival schemes. I submit that the section of the Act which I have quoted empowers authorised undertakings to come to such arrangements as they think proper."

The Lord Chief Justice: With the approval of the Commissioners.

Mr. Ross-Brown agreed, but he said it did not say anywhere in the Act that the Commissioners should have a voice in selecting the specific undertaking.

Mr. Justice Greer: They have not; they have refused to approve because they think there is an opportunity to have something better.

The Lord Chief Justice: How can a body or individual who is required to decide on a question of approval consider one particular plan to the exclusion of all others? Is it not material to the question to compare it with others?

Mr. Ross-Brown: In the present case there was no other application before the Commissioners; the question was whether Hammersmith's application was such as should be granted.

Mr. Justice Greer: It seems to me that your argument is like an application for a rule to exclude from Sec. 19 of the Act the words "with the approval of the Electricity Commissioners." Of course, you do not mean to ask for that, but your argument goes to that.

After further argument, the Lord Chief Justice said the rule could not be granted.

Mr. Ross-Brown asked for leave to appeal, but the Lord Chief Justice replied that leave was not needed. "If it were," he added, "this Court would not encourage it."

On Monday, Mr. S. J. Turner, on behalf of Ealing Corporation, applied to the Court of Appeal for a rule *nisi* for a mandamus directed to the Electricity Commissioners to show cause why they should not give their approval to the provisional agreement entered into between the Ealing Corporation and the Hammersmith Borough Council. The application was made to a Divisional Court on Friday last but it was refused. Having referred to the fact reported above, counsel said the ground of the Corporation's objection to the decision of the Commissioners was that, in considering the application, the Commissioners had taken into consideration purely extraneous matter which they were not entitled to consider at all. Applicants said that the discretion given to the Commissioners by sec. 19 of the Electricity (Supply) Act, 1919, had not been exercised by the Commissioners judicially.

In the result their lordships granted a rule and directed that the form of the rule should be settled in the Crown Office.

Electricity Company's Claim.

At Stamford County Court, last week, Judge Dobb heard the claim of the Urban Electricity Supply Co. to recover from Alfred Cade £34 4s. 6d., alleged to be due for electricity supplies. An affidavit by defendant admitted £23 9s. of the claim, and the dispute arose over the difference in price for electricity consumed for lighting and that for heating.

It was stated that in Sept., 1919, a contract, which had been in existence, was cancelled by the company. They were prepared to enter into a fresh agreement, but after several letters had been sent, a postcard was received stating that it had been decided to have the current on the flat rate. For three quarters in 1920 an allowance had been made for the current used for heating, but afterwards the company said that if a rebate was expected defendant must have a separate meter for the electricity consumed for heating.

Defendant said that the business had been transacted by his wife and daughter, who had come to an arrangement with the company to have the current for heating at a lower rate, but the company's engineer (Mr. Holman) denied any agreement had been come to by his wife who was away at present.

In the absence of proof of a verbal agreement, his honour gave judgment for plaintiffs for the amount claimed.

Award Against Herr Stinnes.

The Anglo-German Mixed Arbitral Tribunal has issued its decision on the claim by Mr. Arnold Lupton, mining engineer, against Herr Hugo Stinnes, of Mühlheim-Rühr, Germany. Mr. Lupton sought to recover £2 000 (with interest at 5 per cent. per annum from October, 1913) under the provisions of Article 296 of the Treaty of Versailles. The claimant entered into an agreement with Herr Stinnes on June 19, 1913, to secure a lease of 900 acres of a coal area near Barnsley, in consideration of the above-mentioned sum being paid to him if negotiations resulted successfully.

It was contended on behalf of respondent that the terms had not been finally negotiated before August 4, 1914, the date of the declaration of hostilities, and that claimant had not completed his part of the contract.

The tribunal, however, decided that the contract had been performed by the claimant, and ordered that £2 000, with interest at 5 per cent. per annum from October, 1913, should be credited to the British Clearing Office, together with £50 to cover the costs.

Damage to Telephone Wires.

In the Court of Appeal (Lords Justices Bankes, Scrutton and Atkin) last week Liverpool Corporation appealed from a judgment of a Divisional Court reversing a decision of the County Court Judge of Liverpool who had found against the Postmaster-General on his claim against the Corporation to recover the agreed cost (£40 8s. 7d.) of repairing damage done to telephone wires and plant by an electric light main belonging to the Corporation. The electric light cable had been laid in 1889 and enclosed in an iron pipe or conduit; the telephone wires were in an adjoining iron pipe but underneath the electric cable. On August 6, 1918, there was an escape of electric current through a breakdown of the insulating material of the electric cable, causing an explosion which damaged both the cable and the telephone wires.

At the conclusion of the legal argument their lordships reserved judgment.

Theft of Wire.

Two youths, named Leslie Isaacs and George Haines, were charged at Cardiff Police Court last week with stealing three coils of wire (valued at £3 9s. 8d.) from John Ryan, a local electrical contractor. Arthur Lawrence, an electrician, was also charged with receiving the coils from Isaacs. Lawrence pleaded that he purchased the material and also other electric fittings (the subject of further charges) from Isaacs, who told him he was in business and represented that he wanted to dispose of the goods because there was no trade. He paid a fair price for everything and had no knowledge that it had been dishonestly obtained.

Isaacs was fined £10, or two months' imprisonment, and Haines £3, or one month's imprisonment. Lawrence was committed for trial at the next Quarter Sessions.

A reduction is announced in the Canadian duties on 50 articles. The reduction applies almost entirely to imports under the British preferential tariff, the exception being agricultural implements, which, being imported wholly from the United States, are also reduced in the general tariff. On a number of items the British preference is increased by an average of 2½ per cent. To provide additional revenue the sales tax is increased 50 per cent., and other taxes are also increased. The regulation requiring foreign goods to be marked with the name of the country of origin is repeated as a general law, but will be applied in special cases by an Order in Council. Henceforth also goods will be valued for duty at the market price in the country of production, while the exchange rate is to be as certified on the invoice by the Consul or commercial agent at the port of shipment.

Parliamentary Intelligence.

Torquay Corporation Bill.

A Select Committee of the House of Lords has passed this Bill, which authorises the transfer of the Newton Abbot electricity undertaking of the Urban Electric Supply Company to Torquay Corporation.

Mr. W. J. Jeeves, K.C. (for the promotors), urged that Torquay needed a more adequate station than it possessed in order to meet the demand for electrical energy in the district. A big station within the borough might be detrimental to the town as a whole, and they had to get outside the borough to find a site for new works. The Urban Electric Supply Company would also have to extend their works. For some reason they declined to supply the Council's workmen's dwellings with electrical energy. In the end Torquay Corporation and Newton Abbot Urban Council met and came to the conclusion that it would be to the interest of both areas that the Newton Abbot Council should exercise their option of purchasing the company's undertaking, and that Torquay should find the necessary money. All the Bill desired was that Torquay Corporation should purchase the undertaking at Newton on terms on which the owners were bound to sell to the Newton Urban Council.

Mr. H. F. G. Woods gave evidence in support of the Bill and said that the scheme would provide Newton with a cheaper and better supply of electricity.

In the course of discussion between counsel and the committee in regard to the price of the undertaking, Mr. Jeeves said £66 000 was suggested, but Mr. Woods considered this sum far too much.

Mr. Tyldesley Jones, K.C. (for the Urban Electric Supply Company), said the Bill was absolutely unprecedented. But for the world war the company would be in a very different position, and when the option to purchase by Newton Abbot was agreed to, quite a different set of circumstances was contemplated. He was going to ask their lordships' protection from what could only be a partial measure of confiscation. Torquay was not even an agent in the purchase. It was a fraud, and Torquay sought to avail itself of what was intended for Newton. The local authority in the case (Newton Abbot) was a mere shadow. Torquay was seeking to obtain permission to buy his client's undertaking, and for an alien corporation to come in and expropriate his undertaking upon terms which were unjust, and for the benefit not of the local inhabitants but of the flourishing borough of Torquay, was the grossest injustice.

No evidence was called for the opposition, but the Committee found the preamble of the Bill proved, and suggested that the terms of purchase be arranged by arbitration.

Electricity (Supply) Bill.

In the House of Commons on the 24th ult. this Bill was read second time without a division, Mr. Geo. Balfour having withdrawn his motion for its rejection on a promise that amendments would be considered in Committee.

In the course of the debate, Mr. Marriott said that local inquiries had been held by the Electricity Commissioners at Birmingham, Manchester and Barrow, and the result proved that those progressive industrial districts were strongly opposed to the setting up of joint electricity authorities on anything approaching a compulsory basis, though they were anxious for co-operation between authorised undertakers on a voluntary basis. The best hope of a rapid progress in the development of electricity supply was to be found in the encouragement of private enterprise. It had been computed that the joint electricity authorities would have to borrow £110 000 000 for the purpose of taking over the existing generating stations, transmission lines, &c. The Bill was a gigantic experiment in municipal trading. Instead of the financial procedure being by resolutions of the House, it should be by way of provisional orders.

Mr. Neal said the Government desired to retain Parliamentary control over finance, and he was advised that they had done so. But, as the matter was one of great importance, he was quite prepared to consider with an open mind, in Committee, any amendments to secure that reasonable and adequate protection was given to the House to control expenditure.

Mr. J. D. Gilbert said that if London was to have a cheaper supply of electricity there must be some kind of working arrangement by which many of the smaller suppliers—municipal and others—would be merged into larger suppliers. At present there was chaos, with different prices in different London areas. The system needed reforming, and the Bill would help in doing that.

Wireless Communication on Railways.

Mr. F. Roberts asked the Postmaster-General (House of Commons, May 24) (1) whether he could indicate the results of the experiments undertaken by the Midland Railway Company and the London and North Western Railway Company with regard to the establishment of wireless communication between the more important points on their railway systems; (2) what progress had been made as the result of the extended trial of wireless communication in connection with the British railway system, which was undertaken by the Marconi Company with his consent?

Mr. Pease: Permission was given in 1920 to the Midland Railway Company to establish wireless communications between certain points on their system and to the Marconi Company to conduct tests of such communications on the system of the London and North Western Railway Company. The Marconi Company proposed last year to supplement the preliminary tests on the London and North Western Railway by a more extended trial, and they were offered a licence for the purpose, but the proposal was not proceeded with. So far as I am aware, no experiment in wireless communication on railways have since been carried out.

London-Switzerland Wireless Service.

Mr. T. Griffiths asked the Postmaster-General (House of Commons, May 25) whether the new wireless service which has been instituted between London and Switzerland in competition with the Government Land Line and Cable Service is being conducted under a temporary or permanent licence; and whether, having regard to the importance of this question, he would cause the terms of the licence to be laid upon the Table of the House?

Mr. Kellaway: No licence has yet been issued. Temporary permission has been given to the Marconi Company to start a service between London and Switzerland, but this is subject to withdrawal if a suitable agreement is not arrived at between the Government and the company as to the conditions on which such licences may be granted. The question of the conditions under which licences can be issued is still under consideration. Should such licences be granted their terms will be laid before Parliament.

On Tuesday Mr. Pike Pease gave a somewhat similar reply with regard to the London-Paris service.

Wireless on the s.s. "Egypt."

In reply to Mr. Mills (House of Commons, May 24) Mr. Baldwin stated that no reports had yet been received by the Board of Trade from ships' captains who received the wireless message SOS from the "Egypt," to the effect that they were unable to obtain details of latitude and longitude from the vessel, but reports on the subject were being obtained. The "Egypt" carried three fully qualified wireless operators. Ocean-going passenger vessels which carry more than 200 persons in all were required to have three fully qualified operators. Ocean-going vessels, whether passenger or cargo, which had less than 200 persons on board, carried one or two fully qualified operators, as the case might be, and, in addition, one or two certificated watchers.

Yorkshire Electric Power Bill.

This Bill has been passed by the Unopposed Bills Committee of the House of Commons. Powers are conferred for the sub-division of the shares for the doubling of the capital of the company, &c. The Electricity Commissioners have authorised the erection of a new generating station at Ferry Bridge, and as the company are to proceed with the scheme the additional powers are necessary. The share capital will be increased from two to four million pounds, with the usual borrowing powers.

The Bill was read a third time on Monday.

Select Committee's Telephone Report.

Replying to a question by Major Glyn in the House of Commons on May 25 Mr. Chamberlain stated that an opportunity for a discussion on the Report of the Select Committee set up to inquire into the telephone services of the Post Office was afforded on the Post Office Estimates, and the Postmaster-General himself dealt with the most important recommendations of the Report. He (Mr. Chamberlain) could not give special facilities for a further discussion.

Wireless on Passenger Aeroplanes.

In reply to Sir H. Brittain (House of Commons, May 22), Captain Guest said that he hoped that long before the end of the year all machines, British and foreign, travelling between this country and other countries would be equipped with wireless.

Progress of Private Bills.

The Ayr Burgh (Tramways, etc.) Order Confirmation Bill passed its third reading in the House of Lords last Thursday.

The Ayr Burgh (Electricity) and the Torquay Corporation (Electricity) Bills were read a first time in the House of Commons on Tuesday. The Grampian Electricity Supply Bill and the L.C.C. (Tramways and Improvements) Bill have been read a third time and passed, and the London Electric and City and South London Railway Companies Bill has been read a second time. The House of Lords have agreed with the Commons amendments to the Nottinghamshire and Derbyshire Tramways Bill.

Aids to Rural Contentment.

In a communication to "The Times," a correspondent strongly advocates, as Aids to rural contentment, new and better houses, a better system of lighting, and better means of transport between towns and villages. Improvements in methods of lighting have not received the attention they deserve, especially in the small towns and villages. No doubt if Joint Electricity Authorities could be formed much would be done to extend electric lighting, but in the meantime there are many places where electric light plants could be established with success and private houses and streets would be lighted better than at present, and at no great cost. It is important to have improved lighting, for better light would compel better houses. Better lighting would mean fuller opportunity for social intercourse, and for so many of the amenities of life, fuller use of the institute buildings, which at present depend for artificial light upon oil lamps. Better means of transport would also aid by widening the intellectual interests of village life and putting neighbouring villages in touch with one another.

Electricity Supply.

During the year ended March 31 last 846 new consumers were connected at WILLESDEN, bringing the total up to 6 636.

Terms have been arranged for the supply of electricity by the Accrington Corporation to OSWALDTWISTLE. For a period of five years an extra charge of 5 per cent. is to be made, but afterwards the same price will be charged in both districts.

HEMEL HEMPSTEAD Rural District Council has sealed an agreement with Watford Urban Council for the supply of electricity to the parishes of Kings Langley and Bovindon. Under the agreement the charge may be 12½ per cent. over and above the price for the time being charged for a corresponding supply at Watford, but the maximum charge must not exceed 9d. per unit.

A conference of electricity authorities in SOUTH-EAST LANCASHIRE will be held in Manchester on June 20, in order to consider the preparation of a draft Order for giving effect to the scheme for the reorganisation of electricity supply in the District which was recently approved by the Electricity Commissioners. The Commissioners will be present at the conference, and it is expected that the Order will come before Parliament in the autumn.

Last year BIRMINGHAM Electric Supply Department made a surplus of £40,858, against £68 160 in the previous year. The accounts last year had to bear heavy charges in the way of interest on the temporary unproductive works at Nechells which are not yet in operation. The proposed system for extending the supply to the eastern and southern districts of Birmingham (at an estimated cost of £100 000) has been altered to a system by which low tension direct current can be made available. A saving will thus be made of £15 000.

The accounts of BEXHILL-ON-SEA Electricity Department for the year to March 31 last show a gross profit of £10 145, an increase of £2 684 on the previous year. After making provision for repayment of loans, income tax, etc., there remains a net profit on the year's working of £2 122 (£517). The credit balance carried forward is £2 639. The committee have decided to reduce the charges for lighting from 10d. to 9d. per unit, and for power from 3d. to 2½d. per unit, the reductions to take effect as from the beginning of the current quarter. Application is to be made to the Electricity Commissioners for sanction to borrow £15 083 for new plant, etc., and the erection of a small sub-station at Cooden to supply the western area, necessary to deal with the requirements of the forthcoming winter.

The Electricity Commissioners have notified CHESTER Electricity Committee that the Draft Order for the North Wales and Chester Electricity District is in the hands of the printers, and that, having regard to the lateness of the Parliamentary Session, the Commissioners had decided to issue the Draft Order not only to the members of the Provisional Committee, but to all interested parties, and to hold the second inquiry at Llandudno on June 13. At their meeting last week the Committee resolved (1) to enter a protest both against the procedure which the Commissioners propose to adopt and against the date on which it is proposed to hold the second inquiry, as not allowing sufficient time for consideration of the terms of the Order; (2) that the services of Mr. J. H. Rider, of the firm of Preece, Cardew and Rider, be retained to advise the Corporation on the technical portion of the scheme.

Arising out of a statement made at a recent meeting of the HULL City Council by Mr. B. Pearlman, that five members of the Corporation had shares in the Melton Cement Company, which had been given exceptionally good terms by the Electricity Committee, it was moved by Mr. E. E. Keighley, at a meeting of the committee last week, that all the members should give the chairman a list of firms or undertakings in which they are interested. The resolution was seconded by Mr. A. Digby Willoughby, and carried without any dissent. With regard to reducing the tariff it was stated that this would not be entertained until the reserve fund was brought up to a reasonable figure. Compared with last year, there had been an increase in the sales of 28 per cent., and the gross revenue had increased by 15 per cent., while the revenue expenses had decreased by 3 per cent. The reserve fund amounts to £13,000, half of which is earmarked for the purchase of inter-connecting machinery.

New Schemes and Mains Extensions.

MULLINGAR Motor Co. have submitted to the Town Commissioners a scheme for the electric lighting of the town.

A company has been formed at TREGARON to carry out an electric lighting scheme, promoted by Dr. J. T. Lloyd.

CHULMLEIGH (Devon) Parish Council have decided to have the town lighted by electricity, and to install eighteen 100 c.p. lamps.

GOUROCK Town Council have agreed to accept the offer of Greenock Corporation to supply the town with electricity, on the same terms as those on which electricity is being supplied to Port Glasgow.

The Minister of Transport proposes to confirm the CAERPHILLY ELECTRICITY SPECIAL ORDER, 1922, authorising the supply of electricity by Caerphilly Urban Council, and any objections must be sent to the Secretary, Ministry of Transport, by June 10.

The proposal of SALFORD Electricity Committee to erect a generating station at AGECROFT was finally approved by Salford Council last week and application is to be made to the Electricity Commissioners for sanction to borrow £709 287 to cover the cost of erection. A heated discussion took place concerning the financial details of the Committee's proposals, but the scheme itself met with little opposition.

The Electricity Commissioners will hold a LOCAL INQUIRY at the Guildhall, Nottingham, on Tuesday, July 11, at 10.30 a.m., and following days, with reference to the area to be included in the proposed East Midlands Electricity District and to consider a scheme which has been submitted by the Conference of Municipal Electrical Undertakers for the improvement of the organisation for the supply of electricity within the said district and for the establishment of a Joint Electricity Authority. Anyone interested may attend the Inquiry. Any representations or objections with regard to the scheme should be addressed to the Secretary, Electricity Commission, Gwydyr House, Whitehall, London, S.W.1, not later than Tuesday, June 27.

GLASGOW Corporation has agreed to apply to the Electricity Commissioners for a Special Order extending the limits of supply of the Corporation so as to include the districts of Killermont, Lambhill, Bishopbriggs, Robroyston, Millerston, Ruchazie, Baillieston, Mount Vernon, Broomhouse, Carmyle, Cardonald, Hillington and the other areas adjacent thereto in the counties of Lanark and Renfrew. The Corporation has had no important extension of its electric lighting area since the original Electric Lighting Order was obtained in 1890. Various districts have been added to the area by Corporation Extension Acts, but a number of these districts were at the date of annexation already possessed by the Strathclyde Electricity Supply Co., and the Clyde Valley Electrical Power Co., and the extension of the city boundaries over these districts was, so far as concerned electricity, subject to the rights and powers of these companies in the annexed areas.

Diverse views were expressed at a combined meeting of the BARRY Urban Council, the Property Owners and Ratepayers' Association, and the Chamber of Trade held last week to consider further the question of the council entering upon an electrical scheme. Mr. W. Seabrook, representing Sir Charles Bright and Partners, who are advising the council, said that as a commercial proposition the installation of an electrical supply was one that required careful consideration. The council were relying upon the local ship-repairing and engineering firms and the authorities in control of the docks to take a supply of electricity, but the council would not be able to produce power as cheaply as the dock authorities could. Mr. Seabrook's firm had previously reported that an electrical scheme at Barry would prove remunerative and that a capital outlay of £20 000 would be required for generating plant and £20 000 for mains. It was suggested that current for industrial purposes 4d. per unit, but workshop proprietors would not look at it at that price, as they required it at about 2½d. Replying to a question, Mr. Seabrook said the lowest cost of installation and wiring was now 22s. per point. Eventually it was decided to defer the matters for a conference between a sub-committee composed of members of the council, the Chamber of Trade, the Ratepayers' Association and the general public.

Alteration of Charges.

DERBY Electricity Committee recommend a reduction in the price of electricity from 2d. to 1¾d. per unit from July next. This will mean a saving of £10 000 a year to users.

Messrs. J. & W. Purves are applying to the Electricity Commissioners for a Special Order to amend the TEIGNMOUTH ELECTRIC LIGHTING ORDER, 1915, by increasing the prices which may be charged, and providing for a periodical revision of such increased prices.

ILFORD Urban Council has adopted the following scale of charges for electricity supplied to cinemas:—Primary charge of 5s. per kW of maximum demand per week; secondary charge, up to 10 000 units per quarter, 3d. per unit; 10 000 to 20 000, 2½d., beyond, 2d. Accounts are to be paid weekly.

STIRLING Town Council has made the following reductions in the charges for electricity: private lighting, from 8d. to 7d. per unit (reduction of 12½ per cent.); slot meters, from 8d. to 7d. (reduction of 12½ per cent.); power 4d. to 1¾d., plus 25 per cent. instead of 57½ per cent. (reduction of 32½ per cent. in the war increase; heating, first 160 units, per quarter, 2¼d. per unit, all over 160 units, per quarter, 2d. per unit (a decrease of from 16½ to 33⅓ per cent.).

RAWTENSTALL Electricity Committee has revised its system of charging for electricity supplied to dwelling houses of £20 rateable value and under. Instead of the present flat rate, a consumer may elect to have a fixed charge of £2 12s. per annum (payable quarterly) for 82 units, including meter rent, but all units used in excess of 82 are to be charged at 1½d. per unit. For houses on the Corporation's housing estates a weekly charge of 1s. will be made and collected each week with the rent.

Business Items, etc.

Mr. C. M. Cosby, northern district office manager of The Westinghouse Morse Chain Co., has joined (as from June 1st) the firm of Jenks Bros., Ltd., of Wolverhampton, who have been appointed sole agents for Yorkshire for the Westinghouse Morse inverted tooth rocker-joint chain drives. Mr. Cosby will be located for the time being, at Standard Buildings, City Square, Leeds.

Shenton and Company announce that they have been appointed agents by the Mullard Radio Valve Company for all their manufactures such as valves, grid leaks, etc., for the districts of Newport and Cardiff. Shenton and Company have been developing wi less apparatus during the past twelve months, and have just issued a four-page list of their receiving sets, accessories and parts for use where it is desired to make up receiving sets complete by the user, as well as for additions to existing sets.

Lionel Robinson and Co. (partners: Lionel Robinson and W. E. Warrilow), 3, Staple Inn, London, W.C.1, have been appointed selling agents for the Moler Fireproof Brick and Partition Co., Ltd., for the handling of their Moler refractory material which they are putting on the market for electric cookers, fires, grills, hotplates, etc., under the trade name of Radmolite. Enquiries will be welcomed at the above address and samples of solid Radmolite can be supplied on application. The company also handles "Moler" in porous and granular form for the thermal insulation for electric ovens, furnaces, etc.

Mr. Ernest A. Marx has resigned his position with Pope's Electric Lamp Co., and has joined the Z Electric Lamp and Supply Co., of 73, Newman Street, W., as joint managing director as from June 1. Mr. Marx first became associated with the Pope's Electric Lamp Co. sixteen years ago, and at the time of his retirement from the firm occupied the post of general manager. He has an unrivalled experience of the electric lamp industry, an experience not confined to this country alone, for he spent over seven years in Australia and New Zealand. He is a member of the Electric Lamp Manufacturers' Association and also of the Executive and Council of the E.D.A. The object of his present change is to extend his operations. As joint managing director with Mr. James Scrivener he will still be in a position to handle Pope Elasta Lamps, as well as all other association makes, together with other electrical supplies, such as moonstone glassware, heating and cooking apparatus, etc.

Electric Traction.

Radcliffe (Lancs) Council has decided to reduce the price of electricity for tramways from 1·9d. to 1·7d. per unit.

A swarm of bees stopped the tramway service at Maidstone on Tuesday by settling on the trolley-pole of a car in the main street. A local bee-keeper had to remove the swarm.

Ayr Town Council have agreed to purchase from Manchester Corporation five single-deck cars at the price of £120 each. The carriage will be £30 per car, and about £100 will have to be expended to make the cars suitable for local conditions.

During the recent intense heat 1 000 000 c. ft. of air was pumped per minute through the tube railways by means of huge electrical fans. The system of ventilation is thoroughly scientific. Some of the fans used are exhaust fans, to draw out exhausted air. Others are pressure fans, to force in fresh supplies, and in the latter case all the air is first washed and ozonized.

The Department of Overseas Trade report an opportunity for British nationals or organisations to purchase certain shares in the Posen Tramway Company, which are held by the Reparation Commission, in accordance with Article 260 of the Treaty of Versailles. A provisional allocation of these shares will be made at the office of the Reparation Commission in Paris on June 10th in favour of the highest offer received up to that date, and any further offers (which must be at least 5 per cent. higher than any previous offer) will be considered on June 17th. Further particulars can be obtained from the D.O.T.

A statement of the works proposed for the improvement and extension of the railways of the Underground Railways Company of London has been issued by the chairman, Lord Ashfield. Particulars of these have already appeared in The Electrician. It is stated that when the new works are finished the capacity of the train service upon the sections of railway concerned will be more than doubled, and it will open up for development a new territory in the north of London. Contracts have been placed for a large part of the works. In about a year the first portion will be completed and opened for public use, the remaining portion being finished in about two years from now. The whole of the rolling stock, rails, bridges, turbo-alternators, machinery, cables, etc., with the one exception of certain parts of the escalators, will be manufactured in this country.

In reference to our article on the 19th ult. relating to the New Zealand national scheme of electricity supply, we are informed that the transformers for Mangahao scheme were ordered from Ferranti, Ltd., and they are now approaching completion. The order comprises seven 4 000 k VA single-phase 50-cycle oil-immersed forced-cooled transformers, ratio 11 000/110 000 V.

Personal and Appointments.

Mr. H. Leigh Mossley has been elected chairman of Willesden Electricity Committee in succession to Mr. W. A. Hill.

Mr. A. J. Abraham, tramway manager and electrical engineer to the Aberdare Urban District Council, intimated to the council at a special meeting on Friday that he had been offered a post elsewhere, but was prepared to remain at Aberdare provided his salary did not fall below £600 per annum. It was stated that Mr. Abraham's basic salary was £460, plus bonuses, making it in all £700 a year. The council accepted the resignation with regret, and resolved to advertise for a manager at a basic salary of £450 per annum, plus bonuses.

Mr. Marconi, with two technical assistants, left Southampton on Friday on board his yacht "Elettra" for America. At New York he will conduct a number of tests in co-operation with some of the modern American stations, and show what can be accomplished in the high speed dispatch and reception of messages. Over long distances, such as from America to England, messages are now received at a rate of eight to ninety words a minute, and Mr. Marconi will use improved instruments by means of which speed can be increased up to one hundred words a minute and over. Besides his other experiments, Mr. Marconi will carry out tests for the Meterological Office in London during his voyage. These will have special reference to the collection of reports of the weather in the areas of the Azores and the Bermudas. He expects to be absent from England until the middle of July.

Wireless and Telegraph Notes.

Arrangements have now been completed for the establishment by the Commercial Cable Co. of a base at Queenstown for the repair of Transatlantic cables.

The wireless station at Abu Zabel is now open for full wireless public service between Egypt, the Sudan, Syria, and the British Isles, and the Continent of Europe.

The English wireless concert transmitted each Tuesday evening from Writtle, Essex, will take place in future at 8 p.m. British summer time, on a wave length of 400 metres; not at 7 p.m. on a wave length of 700 metres, as hitherto.

Marconi's Wireless Telegraph Co. announce that the telegraph office at Marconi House is now open at the following times only:—Monday to Saturday inclusive, from 7 a.m. to midnight; Sundays and Bank Holidays, from 8 a.m. to 11 p.m. During the time Marconi House is closed cyclists will collect messages on receipt of a call to London Wall 3606.

Nauen wireless station is being extended to meet the increasing traffic in the United States and the Argentine. Twenty five million marks additional capital is being raised by the Trans-Radio Co., and a beginning has already been made with the constructive work. The plans include the erection of seven new masts, each 210 metres high (689 ft.), and the dismantling of four of the existing masts.

An Exchange Telegraph message states that the Deutsch Atlantische Telegraphen Gesellschaft, which lately absorbed two other German cable companies, has announced its intention to lay a submarine cable from Emden to Horta (Azores) and from there to New York. An agreement with this object has already been entered into. Negotiations are proceeding with the German Government for compensation to the three companies for losses caused by the war.

Imperial Notes.

Last year the Ontario Legislature passed an Act authorising the Government to bear 50 per cent. of the cost of extending primary distribution lines of the Hydro-Electric Commission in rural areas, but in a Bill recently introduced this privilege will be extended to municipalities that may be in a position to purchase power from private companies. It is not intended to allow a rebate to a private company that may be constructing rural primary lines, but a township or a group of farmers may build primary lines and own them, the Government paying 50 per cent. of the cost.

A Bill has also been introduced into the Ontario Legislature dealing with the construction and operation of municipal electric railways. On the demand of the corporations of two or more municipalities, in any locality in which electrical energy is supplied by the Hydro-Electric Commission, the latter as the agent of and at the expense of such corporations, may investigate the cost and advisability of constructing the desired railway. The proposal must be submitted to a vote of the electors and conditions are laid down for raising money for the work, and for the appointment of an Association to control the equipment and operation of the railway. Any group of municipalities may build electric railways, but the Hydro-electric Commission must approve of the work, and power to operate the system must be purchased from the Commission. The Government desire to assist municipalities to build radial lines where there is a reasonable guarantee of financial success.

Foreign Notes.

The scheme for utilising the water power of the Rhone and many smaller rivers is likely to cause great activity in the FRENCH ELECTRICAL INDUSTRY, and it is stated that soon manufacturers will find difficulty in supplying the country's requirements in electrical machinery and apparatus.

In an article in the last issue of "Eclairage et Force Motrice," M. Paul Basiaux estimates that at least 100 000 H.P. could be obtained from the WATER POWER of the MEUSE and its affluents, of which 50 000 H.P. could be developed in Belgium, and he pleads for the collection of data on the subject.

The accounts of the SOCIETE BELGE POUR LA FABRICATION DES CABLES ET FILS ELECTRIQUES show a net profit of 750 000 frs. in 1921, compared with 1 248 000 frs. in the previous year, and the dividend is only 36.10 frs. per share against 45.62 frs. Owing to the French tariff a subsidiary company, the Société des Cables et Tubes du Nord, of Roubaix, has been obliged to erect a factory in France.

DUTCH MANUFACTURERS OF ELECTRICAL MACHINERY and apparatus continue to complain of the disastrous effects of German competition. The N. V. Nederlandsche Kabelfabriek attribute the drop in their profit in 1921 to 1 106 000 florins, compared with 1 588 000 florins in 1920, to this cause, and the dividend is only 17 per cent. compared with 23 per cent. in the previous year.

LUXEMBOURG will shortly decide upon the offers recently submitted for the electrification of the whole of the Grand Duchy. About 15 tenders were received and the concession will be for 30 years. A commission of three officials, presided over by the Director-General of Public Works (M. Leidenbach), is investigating the various schemes which have emanated from Belgium, French and German firms. Two foreign engineers, one of whom is a Belgian, have been called in, and it is anticipated that a Belgian offer will be accepted.

Ma Hui-chieh and other capitalists have raised a sum of $5 000 000 for the establishment of the KIAO-AO ELECTRICITY COMPANY, LTD., at Tsingtao. The company will undertake electrical enterprises along the Kiaochow-Tsinan Railway. Its head office will be situated at Tsingtao with branches at Tsinan, Shanghai and Tientsin. The TIAO HUA ELECTRIC LIGHT COMPANY, LTD., at Tipu, Chekiang, has been established by Lang Er-k'ang and others. Application for registration has been sent to the Ministry of Agriculture and Commerce through the Board of Industry of Chekiang.

The BUDAPEST correspondent of "The Times" reports that a Hungarian engineer named Szabo claims to have invented a device for printing at limited distances by electric current as well as by wireless. The apparatus can be fitted to any telegraph transmitter. Complete sentences are set up in lines and columns in the transmitting apparatus, and a corresponding impression is conveyed to the receiver either by electric current or by wireless waves. The invention, it is said, will make it possible for newspapers to appear simultaneously in different parts of the world.

There are 1 121 miles of SWISS ELECTRIC RAILWAYS, including 700 miles of light railways. Of the main lines 317 miles are equipped on the single-phase and only 82 on the three-phase system. The mean annual consumption of energy per ton kilometre in 1920 ranged from 48 to 51 units. Electric locomotives are cheaper to maintain than steam locomotives. On the Loetschberg line maintenance is 17 per cent. lower, and on the narrow gauge Rhaetian railways 27 per cent. lower. The Loetschberg electric locomotives are of from 2 000 to 2 500 H.P., and the comparison is with steam locomotives of less than half that power. Swiss opinion favours the single-phase system, using current direct from the generating station supplied at high tension to the contact wire.

In connection with the MARSEILLES COLONIAL EXHIBITION an interesting congress on the applications of electricity is being organised by the Association des anciens élèves de l'Institut Electrotechnique of Grenoble, and will be held in Marseilles from the 17th to the 20th inst. Papers (followed by discussions) will be read on the generation and transmission of electrical energy, including large power units, high tension transmission, switchboards, insulators, and safety devices; electric traction systems; domestic electrical apparatus; electricity in mining, iron and steel works; use of blast furnace gases, electric propulsion of ships, &c., radio-telegraphy and telephony, and electro-chemistry and electro-metallurgy. Particulars may be obtained from the Director of the Institut Electrotechnique, Grenoble.

The "Journal" of the British Chamber of Commerce of Turkey and the Balkan States reports that the CONSTANTINOPLE market is flooded with CHEAP FOREIGN ELECTRICAL GOODS, German to a very great extent, and the prices charged are from 30 to 50 per cent. lower than British prices. Shortly after the armistice a British make of lamp was to be seen in most of the retail shops, and it held its own until the rise in the exchange and the reduction in price of Dutch and German lamps made further business impossible. Many orders for cables have been placed in Germany, Czecho-Slovakia and Italy. Lately few orders have gone to the United Kingdom. British firms are handicapped by the fact that the public utility companies in Constantinople are mostly French or Belgian.

Miscellaneous.

Mr. Henry Chitty has applied for the RESTORATION OF PATENT No. 121 320, dated December 5, 1917, for "Improvements in or relating to commutators for dynamo electric machines," which expired on December 5, 1921, owing to non-payment of renewal fee.

Members of the brass and nickel silver trades last week attended demonstrations of a new type of ELECTRIC ROTATING FURNACE designed and made by T. H. Watson and Co., of Sheffield, for the proprietors of the Greaves-Etchells electric steel furnace. The furnace is of independent arc type of 2 cwt. capacity, in the form of a barrel, which is rotated when a bath of metal is formed, in order to ensure the complete mixing of the alloy. The demonstrations showed a considerable reduction in cost on present methods. This is said to be the first British-made electric furnace adapted for the melting of non-ferrous metals to be put on the market.

For the purpose of thanking the tramway employees for their assistance to his distress fund the Lord Mayor of CARDIFF (Councillor F. H. Turnbull) gave a reception to the tramwaymen on Sunday at the City Hall, and announced that the conductors had collected over £950 since the scheme of selling distress tickets on the system was inaugurated. He hoped the efforts put forward would not be diminished as, owing to the unemployment benefits being restricted, there was still urgent need for more funds. The Lord Mayor was supported by Councillor Sydney Jenkins (chairman of the Tramways Committee), Mr. R. L. Horsfield (general manager), Mr. Howell David (traffic superintendent), and about 200 employees.

Alden Lighting Plants at the Royal Counties Show.

At Stand No. 35 at the Royal Counties Show, Guildford, the ALDEN ENGINE CO. have a representative exhibit of their lighting plants for country-house work, designed to compete with the small high-speed American and other sets, and selling at prices substantially below the quick-speed installations. The engines furnishing the motive power for driving the Alden sets run at slow speeds of 500 to 600 revs. per min., and they are consequently suitable for general power purposes as well as generating electricity.

The sets exhibited include the Alden-Light Plants: Model "C," 2 kW, 50 V, capable of supplying 100 lights, consisting of a 5 B.H.P. Alden vertical oil engine mounted on extended girder frame, and belted to dynamo, complete with water-cooling tank, tool-box, etc., and hand-operated switchboard, including shunt regulator. (The standard battery for this set is one with a capacity of 200 Ah. at the 10-hour continuous rate of discharge); an Alden-Light plant, model "C," 2 kW, 50 V, capable of supplying 100 lights, which is the same as the previous model, except that the engine and dynamo are direct-coupled; and an Alden-Light Plant, model "A", ¾ kW, 25 or 50 V, capable of supplying 30 lights or more.

On the same stand is exhibited one of the Company's new semi-automatic switchboards for use in connection with small electric lighting sets, which permits of the engine being started up automatically from the battery by merely turning a starting switch.

Electricians' Wages.

It is announced that, in accordance with the National Wages Agreements between the National Federated Electrical Association and the E.T.U. (under date August 7th, 1920 and September 22nd, 1921) the variation in cost of living now justifies a 22 per cent. reduction in wages in place of the previous reduction of 16 per cent., the net hourly rates of pay applicable to the respective grades of the agreements are as follows: Grade A, 1s. 11½d. (this rate includes a travelling allowance); Grade B, 1s. 9d.; Grade C, 1s. 7½d.; Grade D, 1s. 6d. The above rates come into effect to-day (June 2nd), for the period covered by that pay day, and will remain current up to and including the period covered by the first pay day in October, 1922.

At the meeting of the N.J.I.C. held on May 24th, 1922, the agreement to vary the grading of Sussex from Grade "C" to Grade "D" was ratified.

Obituary.

We regret to announce the death of MR. JOHN MARTIN, head of the Alternating Current Designing Department of the British Thomson-Houston Co., Rugby, who died on May 23 at his residence in Rugby. Mr. Martin was born at Little Arduthie, in 1878 and was educated at Stonehaven and Aberdeen, studying engineering afterwards at Glasgow University, where he took the degree of B.Sc. On leaving the University he joined the works of the British Electrical Plant Co., at Alloa, as a pupil, and later entered the British Thomson-Houston Works at Rugby in 1903. Shortly after joining these works he entered the designing office and became associated with the design of induction motors and allied apparatus. From 1914 he was in charge of this work, and the high reputation that the B.T.H. induction motors have enjoyed for many years is the result of his energy and ability. Mr. Martin was an Associate Member of both the British and the American Institution of Electrical Engineers.

Tenders Invited and Accepted.

UNITED KINGDOM.

MANCHESTER ELECTRICITY COMMITTEE. June 15.—Cable for six months. Specifications, etc., from Mr. F. E. Hughes, Town Hall, Manchester.

DUBLIN ELECTRICITY COMMITTEE. June 14.—Magazine flame arc lamps. Specification, etc., from the City Electrical Engineer, Fleet-street, Dublin.

TYNEMOUTH CORPORATION. June 26.—One a.c. booster. Particulars from C. Turnbull, Borough Electrical Engineer, Electricity Works, Tynemouth.

PRESTON ELECTRICITY DEPARTMENT. June 28.—E.H.T. switchgear for the Ribble Power Station. Particulars from the Town Clerk, Town Hall, Preston.

METROPOLITAN ASYLUMS BOARD. June 21.—(*b*) installation of electricity for lighting and power, telephones, etc., at Tooting Bec Mental Hospital extension.

MIDDLESBROUGH CORPORATION. June 26.—Laying double line of tramways, equivalent to 1 630 yards of single track. Specification from Borough Engineer.

WEST HAM CORPORATION. June 13.—10 000 kW turbo-alternator and 10 000 kW surface condensing plant. Specification, etc.,from Mr. F. W. Purse, 84 and 86, Romford Road, Stratford, E.15.

DUBLIN UNITED TRAMWAYS CO. (1896), LTD. June 12.—Six months' supply of car fittings, electrical stores, etc. Forms of tender from the General Manager, 9, Upper Sackville Street, Dublin.

ST. PANCRAS ELECTRICITY DEPARTMENT. June 15.—Two sets of motor generator balances, each of 1 000 kW; l. t. cables. Particulars from the offices of the Electricity Department, 57, Pratt Street, Camden Town, N.W.1.

KENT COUNTY MENTAL HOSPITAL, BARMING HEATH, MAIDSTONE. June 30.—Two 3-phase back-geared electric motors and two centrifugal pumps and accessories. Particulars from Handcock & Dykes, 11, Victoria Street, Westminster, S.W.

MANCHESTER ELECTRICITY COMMITTEE. June 28.—Subsidiary cables between generators, auxiliaries, transformers and switchboards in the Barton power station, together with materials for fixing tail-end boxes and pot heads for all the cables as scheduled. Particulars from Mr. S. L. Pearce, Chief Engineer and Manager, Dickinson Street, Manchester.

INDIA.

HIGH COMMISSIONERS OF INDIA. June 23.—(1) Cable, switchboard, lead sheathed, and cable for wiring buildings; (2) cable, dry core, lead sheathed, armoured; and cable, underwater, unarmoured, lead sheathed. Particulars from Director-General, India Store Department, Belvedere Road, Lambeth, S.E.1.

NEW ZEALAND.

PUBLIC WORKS DEPARTMENT OF NEW ZEALAND. July 4.*—Manufacture, supply and delivery of 1 pelton wheel of 225 h.p. direct-coupled to a.c. generator of 150 kVa (120 kW at 0·8 power factor), 3-phase, 2 200 V, 50 cycles, adapted to run in parallel with a 100 kW alternator, all in accordance with specification.

SOUTH AFRICA.

MUNICIPAL COUNCIL OF JOHANNESBURG. June 28*.—Electric lamps and fittings as follows: 5 000 210 V 60 W, 4 000 210 V 100 W, 1 000 210 V 20 W, 5 000 240 V 60 W; one watt metal filament lamp fitted with bayonet type cap, and marked with the letters "J.M.C." The 210 V lamps are required for use on a.c. circuits and the 240 V lamps on d.c. circuits. The following cast iron street lighting suspension fittings are required:—100 fitted with 8½ in. refractor bands and Goliath screw holders, 100 fitted with 8½ in. refractor bands and bayonet holders, 100 fitted with 6½ in. refractor bands and bayonet holders.

LLANDUDNO Electricity Committee have accepted the tender of Whipp and Bourne for l.t. switchboard, £825.

DUBLIN Corporation have accepted the tender of Babcock and Wilcox for two water-tube boilers for the Electricity Department at £35 533.

FARNBOROUGH Urban Council has accepted the tender of Burch and Vertue for wiring and fitting the large hall at the Town Hall at £37 7s. 6d.

BRIGHTON Corporation have accepted the tender of W. H. Allen, Son, and Co., for 400 kW. house service turbine for Southwick power station, £4 662.

WEYMOUTH Town Council has accepted the tender of the BRUSH ELECTRICAL ENGINEERING COMPANY for a commutator for the turbo-generator at £195.

WARWICK TOWN COUNCIL have accepted the tender of the Leamington & Warwick Electrical Company for lighting certain streets in the Stratford-road district.

WOLVERHAMPTON Corporation have accepted the tenders of the English Electric Company (£2 639) and the General Electric Company (£2 902), each for a 1 000 k.W. rotary converter.

* Particulars from the Department of Overseas Trade.

LONDON County Council have accepted the tender of Bolling & Lowe for tramrails, £9 12s. 6d. per ton, fish plates 15s. 3d. per cwt., bolts and nuts £1 12s. 6d. per cwt., and points and crossings £10 5s. per set.

GLASGOW Tramways Committee have accepted tenders of the Western Electric Company and Pirelli General Cable Works, Ltd., for cable, and British Insulated and Helsby Cables, Ltd., for globe strain insulators.

BURNTWOOD Parish Council has accepted the tender of the Cannock Chase Colliery Co. for public lighting by electricity at Chase Town and Chase Terrace at £205 for the season, against £226 12s. 6d. paid for gas.

STEEL, PEECH & TOZER recently quoted the Sheffield Tramways Committee £11 10s. per ton for 500 tons of basic steel rails. As the committee required only 200 tons they placed an order for that quantity at £12 10s. per ton.

EDINBURGH Tramways Committee have accepted the following tenders: Brush Electrical Co., Loughborough, for 119 trucks at a cost of £13 310; and Dorman, Long & Co., Middlesbrough, for tramway rails and fish plates at a cost of £13 456.

BEXHILL-ON-SEA Electricity Committee have accepted the following tenders:—R. Hornby & Co., 150 meters at 36s. each; Landis & Gyr, Ltd., 50 meters at 45s. 8d. each; Crompton & Co., new circuit breakers to No. 5 generator panel, £72 10s. complete with marble panel.

ST. PANCRAS (London) Council have been recommended to accept the tender of the British Thomson-Houston Co. for h.t. switch-gear for Grafton Road and Regent's Park sub-stations, at £3 044. Thirteen tenders were received varying from £3 000 to £5 429. The Council have also accepted tenders of Palmer and Co., Merton, for the supply of 10 switchboard frames, £11 10s.; Northcote, Heaver and Co., 33, King's Road, N.W.1, for 10 l.t. direct-current switchboards, £799 15s.; and Holden and Brooke for an electrically driven 8-stage centrifugal pump, £914 15s.

The "Electrician" Tables of Electricity Supply.

A good idea of the steady growth of the electricity supply industry may be gained from a study of THE ELECTRICIAN Tables of Electricity Supply Undertakings, the 1922 edition of which has just been published. On the present occasion information of about 30 new stations has been included in the British section and over 100 in the Colonial and Foreign Tables. Not only has there been a considerable increase in the number of entries, but substantial progress has also been made in the connections to the mains, in the number of fresh consumers, in reductions of prices, and in other ways.

Apart from the particulars of the chief officials, the systems of supply, consumers' voltage, motors and total connections, public lamps, steam raising and generating plant, prices charged for electric current, etc., hitherto given, information has now been added concerning the types of mains and distributors, converting plant, showrooms, motor hiring and assisted wiring schemes. The whole of the entries, as well as the statistics of the British Power Companies have been carefully revised, and it is confidently believed that the new edition of the Tables will prove indispensable to manufacturers of plant and apparatus, to electrical contractors and suppliers, to power users and others interested in electricity supply.

The Colonial and Foreign Tables have been greatly extended, and no effort has been spared to make the statistics as accurate and as complete as possible for those parts of the British Empire in which there is a demand for electric plant and apparatus. Many Australian, New Zealand, South African and Canadian entries are included for the first time, and through the courtesy of the Overseas Trade Department we are able to give brief particulars of all the supply undertakings in Chili. With the great expansion of hydro-electric supply there should be an increasing market for electrical goods overseas, and the Tables will prove invaluable to manufacturers and exporters who want to open up new colonial and foreign connections.

The present edition also gives particulars of the principal electric tramways and railways in the British colonies and in foreign countries. The Tables are published at the usual price of 10s. 6d., post free, by Messrs. Benn Bros., Ltd., 6 and 8, Bouverie Street, Fleet Street, London, E.C.4.

LICENCES OF RIGHT have been granted to F. Loewenstein for Patent No. 122 040 (1 392 19) for "improvements in electromagnetic wave signalling arrangements"; to Vickers, Ltd., and others for Patent No. 137 379 (1 206 19) for "improvements relating to turbine blades"; to the Vapor Car Heating Co. Inc. for Patent No. 147 177 (19 243 20) for "improvements in electric contact thermostats"; and to Geb. Stork and Co. for Patent Nos. 6 732 15 and 6 733 13 for "regulating and safety apparatus for boiler feed pumps" and "condensing plant."

Companies' Meetings, Reports, etc.

Siemens Brothers.

Addressing the shareholders at the annual meeting of SIEMENS BROTHERS AND CO., on Tuesday, Mr. G. Mure Ritchie (the chairman of the company), who presided, said that their expectations in respect of volume of business and gross profits for 1921 were not realised, because owing to the general decline in industry, so acutely aggravated by the great coal strike, the wave of depression caused their order book to shrink severely, particularly during the second half of last year. Nevertheless, as 1921 results were not subject to excess profits duty, they were able, after making the appropriations already detailed, to carry forward to 1922 a larger amount than was carried forward from 1920 after eliminating the excess profits duty liability for that year.

As to manufacturing operations in 1921, the year's turnover although less than in 1920, exceeded £3 000 000 sterling, and the average profit on the turnover was under 7 per cent. In previous years he had given details of the work in their principal departments, and now, without repetition, it need only be said that throughout, though in most directions on a smaller scale, similar work had been done with similar results. As soon as necessary they hoped to have in substitution for the "Faraday" another cable-laying and cable-repairing steamer of modern type and adequate dimensions, but which would be kept afloat with much lower running charges than was possible with so old a craft as the "Faraday." Business in telephonic apparatus, especially in automatic exchanges, increased substantially during 1921, and, in addition to British orders, included three exchanges for public service in Canada—they had also secured against strong competition from the United States a large contract for a 6 000 line automatic exchange for Winnipeg, but that order was secured in 1922; they had in 1921 contributed substantially towards the progress of submarine telephony by designing and manufacturing cable of the continuously loaded type, their manufacture of ebonite fully maintained its high standard of excellence and their Stannos system of house-wiring continued to make satisfactory headway.

Relations with their employees continued of the most friendly nature, notwithstanding that a comparatively small section of workers connected with one of the engineering unions ceased work some time ago, no doubt out of loyalty to their leaders, whose policy was controlled by a small number of extremists. As compared with the later months of 1921, their orders during the earlier months of 1922 had on the whole increased, and they were, therefore, hopeful that as far as volume of work was concerned they were past the worst. Taking a long view, he thought that in their particular lines of industry the prospects were good. Omitting submarine cables, which might be laid anywhere—though fortunately the chief cable companies had their headquarters in England—their products were delivered in 1921 to Britain 72 per cent., against 67 per cent. for 1920; to their overseas Dominions 17 per cent. in 1921, against 20 per cent. in 1920, and to foreign countries 11 per cent. in 1921, against 13 per cent. in 1920. In their overseas Dominions they had, partly in connection with the English Electric Company, a network of important agencies through which they hoped to build up an expanding and satisfactory business in the future.

An abstract of the accounts was given in our last issue.

Johnson and Phillips.

In the course of his speech at the annual meeting of JOHNSON AND PHILLIPS, LTD., last week, Mr. W. Claude Johnson (the chairman), who presided, said that although the year's profit of £4 737 showed a considerable reduction on last year's profit of £98 405 it was satisfactory to be able to say with confidence that the profit on the year's working would have compared quite favourably with that of the previous year had it not been for the heavy fall in prices of raw materials and stocks which necessitated the writing down of values to current market prices. The year under review, which looked so promising at the beginning, soon became very seriously hampered by the coal strike. The works practically came to a standstill for a time for want of coal. In the meantime some important orders were unfortunately cancelled, with the result that raw materials were left on their hands. Not only were their own works affected, but many firms with whom they did a large business were also compelled to shut down. The reduction in profits would not, however, have prevented the payment of a dividend, as they had an abundance of funds accumulated from undivided profits which would have justified the payment of a dividend. Having regard, however, to the prospective outlook and the present state of trade caused by the engineers' lock-out, and the consequent falling-off of business, the anticipated recovery in trade was being indefinitely deferred. The lock-out had lasted now just over eleven weeks, with the result that the greater part of the works had been closed down during this period. In view of these facts the directors regretted that they could not recommend the payment of a dividend on this occasion. Although a great number of their employees had been locked out in common with those of other federated firms in the engineering trades, they had not given the slightest trouble or anxiety to the management by picketing or interfering with the few non-union men and apprentices who remained in the works. Indeed, they had been helpful and sympathetic in settling the one or two minor incidents. This feeling of good fellowship still prevailed between the workpeople and the management and would have a beneficial effect on the results when a new start was made in the works.

Mr. John Macgregor (managing director) said the strike outlook was rather black at present, but they were hoping that a way out of the difficulty would soon be found and work resumed. There was no doubt that a large amount of work had to be done. Take, for instance, the electrification schemes prepared by the home and Colonial railways, most of which were ready to go ahead immediately financial arrangements had been made, and the Government Electricity Bill for bulk supplies which was now before Parliament, and which, when passed, would mean the erection and installation of huge central stations. There were also the many municipal extensions, which should bring a large amount of work to the industry and incidentally to themselves. There were likewise the proposed extensions of the telephone service by the General Post Office, which would mean new cables, of which they hoped to get a share. There was no doubt that electrical engineering would be one of the very first industries to feel the effects of a trade revival.

An abstract of the accounts appeared in our issue last week.

British Thomson-Houston.

Presiding at the annual meeting of the BRITISH THOMSON-HOUSTON CO. on Tuesday, Mr. H. C. Levis (the chairman and managing director) stated that the volume of unfilled orders on hand at the end of 1920 was such that, notwithstanding the fact that during 1921 the orders received were less in volume than for the previous year, the output for 1921—that was to say, the amount billed to customers—was the greatest in the history of the company. In spite of the general depression throughout the country, the volume of orders received by the company this year to date was over 37 per cent. in excess of the orders received for the corresponding period of 1921. The company now had on hand orders to the value of over £2 250 000. With regard to inquiries, the volume was very large, and while the proportion which had resulted in orders was not as great as in 1920, nevertheless there was still a great demand for electrical machinery, which must be satisfied sooner or later, and from which they confidently expect to get their fair share of business.

In the latter part of the year under review, it was deemed wise to make provision to liquidate the floating debt of the company. An issue of £3 000 000 of debenture stock was authorised, and £1 500 000 par value was issued on satisfactory terms. The issue was largely over-subscribed, and it was satisfactory to note that this stock stood at a substantial premium to-day. Although on the balance sheet there still appeared an amount of £764 000 due to the International General Electric Company, this had since been liquidated, and the only debt which the company had, in addition to debenture stock and employees' savings certificates, was sundry creditors, retentions, etc., which was covered more than three times over by apparatus, supplies, etc., finished and in progress of manufacture, and the sundry debtors, retentions, money, and other outstanding accounts.

A scheme of "Employees' Savings Certificates" had been instituted during the year, which enabled employees to invest their savings by purchasing certificates bearing a fixed rate of interest, and pay for same on an instalment plan. The number holding the Certificates was now over 1 300. During the year the expenditure on factories was over £150 000, all of which was in connection with works started or authorised prior to the year under review, and principally in connection with the new Birmingham factory, the new Glass Works at Chesterfield in connection with the company's electric lamp business, and extensions to the Rugby plant, all of which would be completed during the current year.

The total cost of property, buildings and plant to the end of December last was £2 670 000. From this cost there has been written off sums aggregating £793 286, or over 29 per cent. of the total cost. Owing to the expansion of the company, the offices at Cannon Street had been given up, and the company were now in larger quarters at Crown House, Aldwych.

The memorial to the employees who fell in the war had been completed, and was unveiled by Field-Marshal Sir William Robertson.

An abstract of the accounts appeared in our last issue.

Callender's Cable and Construction.

Addressing the shareholders at the annual meeting of CALLENDER'S CABLE AND CONSTRUCTION CO. last week Sir J. Fortescue Flannery (the chairman), who presided, said that they had been compelled to close their works for more than two months during the year owing to the stoppage in the coal trade. Advantage had, however, been taken of the interruption to institute reforms in their organisation which should lead to permanent and substantial economies both in administration and manufacturing. The net result of the trading, namely, £217 012, was approximately £35 000 more than at the end of 1920, in spite of the trade depression which had continued throughout the year. Their business in India, in spite of grave unrest there, had been carried out successfully. Business from Australia and South Africa had at times been much restricted, but in South America they showed more advance. In their Continental business their most serious diminution of trade had occurred. One of the great difficulties there was the depreciated exchange. The far more important disadvantage which this country had felt the effect of during the last two or three years was the unwillingness of the worker, which had yet to be overcome. The current year showed a reasonable prospect of a successful result, but that must largely depend upon developments during the next few months. The company must depend for its success not only upon a substantial

home trade but upon large orders coming from abroad. The sooner, therefore, that an effective international agreement was reached and industrial peace in this country was secured the sooner the company and others like it would be able to get to work without let or hindrance.

Sir T. O. Callender (managing director) said it had been an exceedingly difficult year for the management, but to a certain extent the stoppage of the coal trade had tended to their advantage. They had not only taken the opportunity thoroughly to reorganise their factories and administration but they had found that when they had resumed work, after nearly ten weeks, their men had thrown off many of the pernicious doctrines which had been upsetting production, and that the ca' canny policy was conspicuous by its absence. It was disappointing that the large extensions in the electrical field, of which so much had been heard, had so far not materialised. From the city of Manchester certainly their company had received the largest order which had ever been placed in the cable industry, and they had had important contracts in various other parts of the country, but the general great development of electricity was still in the lap of the gods, although from his intimate knowledge of what was going forward he thought they could look forward with great confidence to excellent business in the near future. His view was that the long outlook for their trade had never been better than it was at present.

An abstract of the accounts was given in our issue of May 19th.

Oriental Telephone and Electric.

The net revenue of the ORIENTAL TELEPHONE & ELECTRIC COMPANY for the year to December 31 last amounted to £49 228, to which is added the balance from 1920 of £10 492, making a total of £59 720. After deducting £13 076 for interim dividends paid, there remains a sum of £46 644, which the directors recommend should be appropriated as follows:—£24 652 in payment of a final dividend of 6 per cent. on the ordinary shares and a bonus of 2 per cent., and a final dividend of 3 per cent. on the preference shares; £10 000 to depreciation and general reserve; £2 000 to staff pension fund; leaving £9 992 to be carried forward. The business at all the branches of the company—viz., Madras, Rangoon, Moulmein, Singapore and Mauritius, and of the associated companies—continues to expand, and shows increased revenues for the past year. Owing to the fall in the rupee exchange, however, the net revenue from the branches does not stand at so high a figure as in the previous year, but compares favourably with that for the year 1919, in which no abnormal movement of exchange rates occurred. The Government of India have now definitely decided not to purchase the undertakings of the company and its subsidiaries in India in 1923. As the result of prolonged negotiations which have recently been concluded in India by Mr. G. Parker Ness, the vice-chairman of the company, in conjunction with the local companies, the Government have decided to grant security of tenure to the companies until March, 1943. At December 31 last the company had a total of 10 071 stations in operation, an increase of 1 054 during the year. The Indian local companies have declared the following dividends for the year 1921—viz., the Bombay Telephone Company, 14 per cent., and the Bengal Telephone Company, 10 per cent. The annual report of the Bombay Telephone Company has not yet been received, but according to advices already to hand that company had, on December 31 last, 9 885 exchange and private lines in operation, being a net addition of 176 during the year. The directors of the Bengal Telephone Company report that the demand for new telephone services continues to increase and that the prospects for the future are excellent. At December 31 that company had 8 272 stations in operation, being a net addition of 1 434 during the year. The net revenue of the China and Japan Telephone and Electric Company shows a substantial increase over the previous year and a dividend of 10 per cent., free of income tax, for the year has been declared, as well as a bonus of 10 per cent., also free of income tax, in view of the passing of the dividend by that company last year. At December 31, 1921, that company had 6 785 stations in operation, an increase of 673 during the year. The liquidation of the Telephone Company of Egypt, Ltd., has now been completed.

Vera Cruz Electric Light, Power, and Traction.

Presiding at the annual meeting of the above company last week, Mr. Vincent W. Yorke (the chairman of the company) said that the net profits in Mexico for the year 1921 were the highest yet earned since the company was incorporated, and were practically $200 000 (Mexican) higher than they were in 1920. After providing out of the profits for the year for debentures and corporation profits tax there remained a balance of £64 752. An interim dividend of 5 per cent. had already been paid in respect of 1921, and it was proposed to pay a further 5 per cent. dividend, making 10 per cent. in all, and in addition a bonus of 2½ per cent. for the year. This total dividend and bonus would absorb £43 750. £20 000 had been transferred to depreciation and reserve account, this being £5 000 more than they had transferred in any previous year, and £22 983 was being carried forward, approximately £1 000 more than the amount brought into the accounts from last year. The depreciation and reserve account now stands at £95 000. The rate of exchange ruling between London and New York had for the last three years resulted in a profit in respect of all money remitted to London, and profit on exchange for the year 1921 amounted to some £13 000. The bonus to be paid really represented profit on exchange and might not be possible in future years. During the year their investment in the company which owns and operates the bathing establishment at Balneario had been increased by approximately £5 000. Negotiations had been opened with their management in Vera Cruz for a lease of this property. Owing to the popularity of Balneario and the consequent heavy demand for transport and also to cope with increasing traffic generally, orders had been placed for six additional tramcars. The company had received practically the whole of its power from the Tuxpango plant of the Puebla Tramway Light and Power Company, which continued to afford a very satisfactory service.

The GLOBE TELEGRAPH TRUST COMPANY announces a final dividend of 5s. per share net on the ordinary shares.

ALTRINCHAM ELECTRIC SUPPLY COMPANY have declared a dividend of 7½ per cent. for the year. £726 is carried forward.

DOULTON & COMPANY recommend a dividend of 5 per cent. on the ordinary shares for the year. The sum of £53 243 is carried forward.

ALLEY & MACLELLAN announce a dividend of 6 per cent. for the year less tax. £26 227 has been set aside for depreciation, leaving £5 564 to be carried forward.

The directors of the CHLORIDE ELECTRICAL STORAGE COMPANY announce a final dividend of 5 per cent., actual, tax free, making 10 per cent., tax free, for the year. Last year the dividend was the same.

The directors of the ELECTRIC CONSTRUCTION COMPANY recommend a final dividend at 9 per cent. per annum on the ordinary shares, making 7½ per cent. for the year ended March 31 last, plus a bonus of 2½ per cent., both less tax.

The directors of the MADRAS ELECTRIC SUPPLY CORPORATION recommend a dividend at the rate of 8 per cent. per annum, free of tax, for 1921. The CORPORATION on Monday offered for public subscription £200 000 of seven per cent. second (registered) debentures at 95. The issue was more than ten times over-subscribed within a few minutes after the opening of the lists.

The net profit of the THOMSON-HOUSTON (CIE. FRANÇAISE) for 1921, less debenture and other interest and general and miscellaneous charges, was 23 522 422 frs., making with 610 765 frs. brought in 24 133 187 frs. The directors propose to place to redemption fund 3 512 405 frs., to reserve 1 000 500 frs., administrative expenses 900 951 frs., to pay a dividend of 45 frs. per share and carry forward 719 329 frs.

The accounts of DICKSON & MANN for the year ended March 31, after providing for all usual charges, depreciation and half-year's dividend on the preference shares, show a total deficit brought up to £9 000, largely due to heavy fall in value of stock. From reserve the directors have transferred sufficient to meet this deficit. The company have a recognised claim for return of income tax paid, which will considerably reduce the deficit. No dividend on the preference shares can be paid for the half-year. The directors report that as regards volume of business the year has opened favourably.

The accounts of MIRRLEES, BICKERTON & DAY for the year ended March 31, after providing for depreciation and directors' fees, show a loss of £10 552, reducing the balance of £14 369 brought in to £3 817. In arriving at these figures the directors believe they have made sufficient provision for depreciated values of stock and work in progress, and have not over-estimated amount of excess profits which will be recovered. The directors recommend the withdrawal of £10 525 from reserve, paying a dividend on the ordinary shares at 5 per cent., less tax, for the year, carrying forward £2 858 and leaving reserve at £25 000.

The report of the REES ROTURBO MANUFACTURING COMPANY for the eleven months ended August 31 last states that the final adjustments in respect to the Finance Act, 1921 (winding up excess profits duty), under which the company claimed approximately £5 000, has not yet been settled and was therefore not included in the balance sheet. The balance to the credit of the profit and loss account, including £6 727 brought in, was £10 255. A dividend of 5 per cent., less tax, on the preference shares for twelve months ended September 30, 1917 (£2 837), was paid in December, leaving £7 417, out of which the directors recommend payments of a dividend of 5 per cent. on the preference shares for the year ended September 30, 1918, less tax; £2 000 to depreciation reserve, making £17 000; £1 013 to taxation reserve, making £10 000, carrying forward £1 507. £7 555 has been added to capital expenditure for patterns and loose tools.

Addressing the shareholders at the annual meeting of the LANCASHIRE ELECTRIC LIGHT AND POWER COMPANY last week, Mr. Alfred Shepherd, who presided, said that the net result of the company's working, after crediting the interest and dividends received and debiting the interest on the company's debentures and other expenses, and adding the balance brought forward from last year, gave a sum of £40 988 available for dividends. The directors recommended that dividends should be declared upon the 6 per cent. cumulative convertible first preference shares and the 7 per cent. cumulative participating preference shares, after which there would be a balance to carry forward of £8 458. As regarded the future, he hesitated to prophesy. But the returns received from the Parliamentary Company up to date indicated that next year the accounts of this company should show considerably better than those for the past year.

County Court Judgments.

[NOTE.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

BEVAN MANUFACTURING CO., 146, Gooch Street, Birmingham, makers of electro-plate wares. £14 2s. 6d. March 29.

BRADBEER, John E., 2C, Englands Lane, N.W., electrical engineer. £26 5s. 2d. March 14.

CARTER (HUBERT D.), LTD., Edison House, Colwyn Bay, electrical contractors. £11 11s. 1d. March 29; and £57 5s. 9d. April 9.

FISHER, Mr. N., 1, Victoria Square, Holmfirth, electrical dealer. £21 3s. 10d. March 30.

GREENFIELD, Mr. F., 47, Goldhawk Road, Shepherd's Bush, electrical engineer. £15 17s. 6d. March 29.

JOHNSON, Frederick, Esher Street, Upper Kennington Lane, S.E., electrician. £24 12s. April 3.

LEPPARD, F. H. (trading as ELECTRIC EXCHANGE), 45, St. Nicholas Street, Bristol, electrical dealer. £19 15s. 1d. March 23.

ROYSENTUL, Mr. J., 46, Balls Pond Road, N., electrical engineer. £23 15s. 6d. March 28.

SMART, William Nathan (trading as W. N. SMART AND CO.). 19A, Cross Street, Oldham, electrical engineer. £10 0s. 7d March 30.

VENN, Robert (trading as VENN BROTHERS), 39, Turnham Green Terrace, Chiswick, electrician. £21 7s. 5d. March 24.

Bills of Sale.

[The undermentioned information is from the Official Registry. Up to the date the information was obtained it was registered as given below; but payment may have been made in some of the cases, although no notice has been entered on the Register.]

CHAPPELL, William, 26, Alldis Street, Great Moor, Stockport, electrical and mechanical engineer and contractor May 27. £40.

RECEIVERSHIPS.

B.E. MANUFACTURING CO., LTD.—J. E. Pritchard, of 115, Colmore Row, Birmingham, was appointed receiver and manager on May 19, under powers contained in debentures dated February 28, 1922.

CORONA LAMP WORKS, LTD.—V. G. Teale, F.C.A., of 65, Chancery Lane, W.C., was appointed receiver on May 15, 1922, under powers contained in trust deed dated April 10, 1919.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

BRITANNIC ELECTRICAL CO., LTD., Solihull Lodge.—Registered May 11, £250 debentures, balance of £1 000; general charge; also registered May 11, £1 000 second debentures, present issue, £650; general charge. *£750. February 24, 1921.

KELVIN-HARDY ELECTRIC CO., LTD., Liverpool.—Registered May 10, £1 500 debentures, present issue £1 000; general charge. *Nil. December 31, 1921.

NORTHAMPTON ELECTRIC LIGHT AND POWER CO., LTD. —Registered May 6, £40 000 second debenture stock; general charge. *£110 000. March 10, 1922.

RODD (R. J.), LTD., Walton-on-Thames, electricians.—Registered May 16, £4 000 debentures; present issue, £3 500; general charge. *Nil. June 17, 1921.

Satisfaction.

BOMBAY ELECTRIC SUPPLY AND TRAMWAYS CO., LTD. —Satisfactions registered May 9, £600 000 registered November 18, 1905; £150 000 registered May 17, 1909; £50 000 registered March 17, 1911; and £10 000 registered February 17, 1915.

I. T. E. ELECTRIC CO. (1907), LTD., London, E.C.—Satisfaction registered May 23, £2 400, registered December 18, 1907.

Private Meetings, etc.

[*Inclusion under this heading does not necessarily imply failure. Many private meetings are called merely for the purpose of the debtor consulting his creditors as to his position when he may not be insolvent.*]

AQUA ELECTRIC CO., LTD. (in voluntary liquidation), electric geyser, etc., manufacturers, 116, Putney Bridge Road, London, S.W.15. A meeting of creditors was held on Monday, at the Chartered Institute of Secretaries, 59A, London Wall, London, E.C. Mr. C. H. McKnight, 36, New Broad Street, London, E.C., the liquidator, stated that he had prepared a statement of affairs, from which it appeared liabilities totalled £1 586 (trade creditors, £580). Assets estimated to realise £250, or a deficiency of £1 336 so far as the unsecured creditors were concerned. A resolution was passed confirming the voluntary liquidation of the company, with Mr. McKnight as liquidator.

PARK BROS., LTD., electrical engineers, Spring Bridge Road, Ealing, London, W.—Creditors were called together on Friday at the offices of Corfield and Cripwell, accountants and auditors, Balfour House, Finsbury Pavement, E.C. Mr. W. A. J. Osborne, the liquidator in the voluntary liquidation of the company, submitted a statement of affairs which showed liabilities of £277, all due to the trade. The assets were estimated to realise £119, or a deficiency of £158. Mr. Osborne stated that the stock included a quantity of old material which would be very difficult to dispose of. The business was an old-established one, previously carried on under the style of Park Bros., and was converted into a company in December, 1900, with a nominal capital of £1,000, of which £334 represented preference shares and £660 ordinary shares. The vendors received 603 ordinary shares as the purchase price of the business, while 250 preference shares had also been issued. For some years the business was successful, but during the last three or four years there had been losses on the trading. Efforts had been made to introduce further capital, but without success. The creditors passed a resolution confirming the voluntary liquidation of the company with Mr. Osborne as the liquidator.

THOMAS, John, 19, Porth Street, Porth, Rhondda Valley, electrical engineer, etc. At a meeting of creditors held recently in Cardiff, sympathy was expressed with the debtor, and it was decided to accept a composition of 6s. 8d. in the £, payable as to 2s. 6d. in three months, 2s. 6d. in six months, and 1s. 8d. in nine months. It was also decided that the matter should be carried through under a deed of assignment, with Mr. S. E. Clutterbuck, of Messrs. Clarke, Dovey and Co., as trustee, and a committee of inspection. A statement of affairs presented showed liabilities of £1 305 (trade creditors £822), net assets estimated to realise £212, deficiency £1 093. Debtor commenced business in January, 1920, with a capital of about £630, and took over an existing business. At the outset the turnover was £33 per week, but it went up to £45 weekly, but had now dropped to £28 a week. The gross profit was estimated at about 15 per cent., while the outgoings were £13 weekly. The following are creditors:—Baxendale and Co., Manchester, £150; Catterson and Sons, S. P., London, £27; English Electrical and Siemens Co., London, £116; General Electric Co., Cardiff, £26; Rose Bros., Bristol, £34; Siemens Bros., London, £36; Shenton and Co., London, £61; Smith, J. and W. B., London, £25; Witty and Wyatt, Cardiff, £17; Wholesale Fittings Co., Bristol, £23.

TOFIELD AND ROBINSON, LTD., electrical engineers, Edmund Street, Birmingham. At a conference of creditors held recently in Birmingham it was unanimously decided to leave their accounts in abeyance for a period of six months, during which time they would not exercise any pressure, subject to the directors reporting to a committee of inspection every three months, and to a report being issued by the committee at the end of six months. The committee consisted of the representatives of the Callander Cable Co., Sterns Electric Co., W. R. Henley Telegraph Co., the English Electric Co., and the Wholesale Traders' Association. A statement of affairs presented showed ranking liabilities of £10 755 (unsecured creditors, £2 476; bankers, £8 079). Assets consisted of cash in hand, £30; book debts, £2 000; stock in trade and work in progress, £4 500; furniture and fittings, £200; and plant and machinery, £270, or a deficiency of £3 755 7s. 10d. With regard to the claim of the bank, they held debentures to the extent of £8 000. The business was incorporated in May, 1920, and took over the Birmingham business of another concern as from November 1, 1919, paying £1 880 for the goodwill. The first year's trading showed a profit of something like £300, but in the succeeding twelve months there was a heavy loss, which approached £4 000. That loss was largely due to heavy purchases of goods which could not be readily sold, and had since depreciated very seriously in price. The directors had never received any fees. The company also opened a London office which resulted in a loss of over £1 000, and was closed. Economies to the extent of at least £1 300 a year had been effected, and there were a number of profitable orders on hand.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Companies Winding-up Voluntarily.

ALFO ELECTRICAL ENGINEERING CO., LTD.—J. R. Dickin, 37, Moorfields, Liverpool, appointed liquidator. Meeting of creditors at 20, Castle Street, Liverpool, Monday, June 12, at 3 p.m. Particulars of claims to the liquidator by June 6.

MENAI BRIDGE ELECTRICITY SUPPLY CO., LTD.—W. Grey Pritchard, High Street, Menai Bridge, appointed liquidator. Meeting of creditors at the Council Chamber, Menai Bridge, Wednesday, June 7, at 2 p.m.

Bankruptcy Information.

CARTER, Thomas, 2, South Street, Dorchester, and at High Street, Swanage, electrical engineer. First meeting, June 8, 12 noon, Official Receiver's Office, City Chambers, Catherine Street, Salisbury. Public examination, June 23, 10.30 a.m., County Hall, Dorchester.

VELIKOID MANUFACTURING CO., Daw Bank Works, Stockport. Receiving order, May 18. Creditor's petition.

Notice of Dividend.

BECKETT, Samuel, Junior, 50, Deane Road, Bolton, electrician. Amount per £, 6¾d. First and final. Payable, June 6. Official Receiver's Offices, Byrom Street, Manchester.

Notice of Intended Dividend.

GOSS, Frederick Charles, 32, Windsor Road, St. Andrews Park, Bishopston, and 71, North Road, Bristol, electrical engineer, Last day for receiving proofs, June 13. Trustee, F. W. Darley. 26, Baldwin Street, Bristol.

Edinburgh Gazette.

DENHOLM, CRAIG AND CO., electrical engineers, 81, Townhead Street, Hamilton. Partnership dissolved as at April 29, 1922, by the retiral of Alexander Duncan. John Gilmour Denholm and Alexander Gray Craig will continue the business under the same firm name.

HARVEY, Thomas, mechanical and electrical engineer, 31, Arlington Street, Hillhead, Glasgow. A creditor's petition for sequestration has been presented.

Bankruptcy Proceedings.

BATE, Douglas Clavell, 16, John Dalton Street, Manchester, electrical manufacturer and supplier. The first meeting of creditors was held at Manchester. Statement of affairs showed liabilities of £1,959, assets estimated to realise £663, from which preferential claims of £79 had to be deducted, leaving net assets of £584, or a deficiency of £1,375. Debtor attributed his failure to marked fall in prices, his periodical ill-health for the past three years, and his total inability to attend his office since September, 1921. He was in the electrical business for over 40 years as an employee. About 14 years ago he came to Manchester and started on his own account at 40, Brazennose Street, removing to his present address in 1916. Until the armistice the business was fairly successful, but he had two bad periods, one after the armistice, which lasted about six months, and another which started in the spring of 1920 and still persisted. A full set of books of account had been kept. Debtor became aware of his position about the middle of March last. The creditors decided to appoint Mr. J. F. Warburton, 28, Queen Street, Manchester, as trustee. The following are creditors: A. and A. Electrical Co., London, £35; Benjamin Electrical Co., London, £70; Bi-Metals, Ltd., London, £10; Concordia Electric Wire Co., Ltd., New Sawley, £56; Central Electric Co., Manchester, £50; Eureka Conduits and Fittings Co., Walsall, £25; Edison Swan Electric Co., Ltd., Manchester, £46; Efandem Co., Ltd., Wolverhampton, £20; Greenwood and Batley, Ltd., Leeds, £300; Hackbridge Cable Co., Ltd., Hackbridge, £20; Hogan and Wardrop, London, £13; Hopkins, H. H., Manchester, £40; Moores, John, and Co., Manchester, £35; Premier Elec. Contracting Co., London, £16; Record Electric Co., Altrincham, £22; Simmonds Bros., Ltd., London, £160; Steel Tubes and Conduits Co., Keighley, £121; Velekoid Manufacturing Co., Stockport, £81; White, J. C., Manchester, £65.

HENDERSON, Charles Archibald, 63, Queen Victoria Street, E.C. The debtor, who carried on business as an insulating materials merchant, attended for his public examination last week before Mr. Registrar Francke. His statement of affairs disclosed liabilities £24 371 (£23 405 expected to rank), and estimated assets £18 359. The debtor was adjudged a bankrupt on May 22, aud it was now reported by the Official Receiver that his statement of affairs was only filed on May 23. Under the circumstances he asked for an adjournment until July 14. This application His Honour granted. Appended is a list of the principal creditors:—All's Well Paint Co., London, £24; Brooker and Jackson, Ltd., London, £30; Climax Stopper Co., Ltd., London, £234; Ebo Rubber Co., Ltd., London, £857; Fuller's United Electric Co., Ltd., Chadwell Heath, £522; Highlensite, Ltd., London, £57.

New Companies.

Hayward Turbine Engineering Co.

HAYWARD TURBINE ENGINEERING CO., LTD. (181 045). Private company. Reg. May 25. Capital, £100 in 1s. shares. Turbine, electric, irrigation, electrical and general engineers, etc. Subscribers: I. B. Blaiberg and S. Miles. Sec.: S. Miles. Reg. office: Liberty Works, Bollo Lane, Acton, W.3.

St. Helens Motor and Engineering Co.

ST. HELENS MOTOR AND ELECTRICAL ENGINEERING CO., LTD. (182,032). Private company. Reg. May 25. Capital, £600 in £1 shares. To carry on the business as indicated by the title. Permanent directors: H. Devany, E. Filmer, and F. Newton. Secretary: F. Newton. Reg. office: Canal Works, Church Street, St. Helens.

Naylor Benzon Engineering

NAYLOR BENZON ENGINEERING, LTD. (182 004). Private company. Reg. May 24. Capital, £20 000 in £1 shares. Manufacturers and installers of, and dealers in engines, boilers, gearing, machinery, plant and other goods, railway, tramway and road locomotives, etc. First directors: C. S. Ascherson, A. D. Tisdall, and A. C. Hay Solicitors: Lawrence, Webster, Messen and Nicholls, 14, Old Jewry Chambers, E.C.2.

London Magneto Repairing and Winding Co.

LONDON MAGNETO REPAIRING AND WINDING CO, LTD. (182 002). Private company. Reg. May 24. Capital, £3 000 in £1 shares. To take over the business carried on by S. T. Boon, at 78, Hampstead Road, N.W., as the "Magneto Repairing and Winding Co." Life directors: S. T. Boon and H. C. Eade. Solicitor: C. R. A. Edmonds, 61 and 62, Chancery Lane, W.C. Reg. office: 78, Hampstead Road, N.W.

Burke Electrical Manufacturing Co.

BURKE ELECTRICAL MANUFACTURING CO., LTD. (182 020). Private company. Reg. May 25. Capital, £500 in £1 shares. To adopt an agreement with S. Burke, and to carry on the business of electrical and general engineers, manufacturers and patentees of electrical machines and apparatus, etc. First directors: S. J. Burke, W. Dawson, H. W. Penney and H. A. Douglas. Reg. office: 6, Francis Street, Westminster.

Adams Silent Burglar Alarm Co.

ADAMS SILENT BURGLAR ALARM CO., LTD. (181 985). Private company. Reg. May 24. Capital, £4 000 in £1 shares. To adopt an agreement with S. G. Adams, A. B. Adams, G. E. Appleton and A. Adams for the acquisition of Patent No. 33 839 of 1920, for improvements in burglar and like alarm systems, etc. First directors: S. G. Adams, A. B. Adams, W. C. Sayers, G. E. Appleton, A. Adams, F. E. Sayers and O. E. H. Birchall. Reg. office: 58, Leander Road, Thornton Heath.

Wireless Appliances.

WIRELESS APPLIANCES, LTD. (181 984.) Private company. Reg. May 23. Capital £5 000 in 1s. shares. Electricians, manufacturers of generators, accumulators, suppliers and distributors of electricity for lighting, heating, telegraphic, telephonic and signalling communication, proprietors and managers of telegraph, telephone and signalling works, distributors of news, etc. Provisional directors, W. A. Heyland, W. G. Chapman. Secretary, C. H. Kieling. Reg. office: 132 and 134, Shaftesbury Avenue, W.1.

Universal Postal Frankers.

UNIVERSAL POSTAL FRANKERS, LTD. Private company. Reg. May 25. Nominal capital, £100 000 in £1 shares. To adopt an agreement with the Sterling Telephone and Electric Co., Ltd. (vendors and promoters), to acquire and turn to account certain patents and rights, and any inventions relating to machinery for franking letters, telegrams, cablegrams marconigrams, receipts and the like, etc. Subscribers: F. S. Gaylor and J. Findlay. Solicitors: Steadman, Van Praagh and Gaylor, 4, Old Burlington Street, W. File number is 182 037.

Arrangements for the Week.

WEDNESDAY, JUNE 7th.

INSTITUTION OF ELECTRICAL ENGINEERS.

6 *p.m.* At Savoy Place, Victoria Embankment, London, W.C.2. "The Performance of a Radio-Telegraphic Transmitter, with Special Reference to the New Installation at North Foreland," by Mr. N. Lea, B.Sc. "A Dynamic Model of Tuned Electrical Circuits," by Prof. C. F. Jenkin, C.B.E., M.A.

FRIDAY, JUNE 9th.

PHYSICAL SOCIETY OF LONDON.

3.30 *p.m.* Visit to the National Physical Laboratory, Teddington.

The unveiling and dedication of the WAR MEMORIAL in memory of the members of the INSTITUTION OF ELECTRICAL ENGINEERS who fell in the Great War will take place at the Institution building on Wednesday, June 28, at 4.30 p.m. The Memorial will be dedicated by the Rt. Rev. Bishop Ryle, Dean of Westminster, and unveiled by Air Chief Marshal Sir H. M. Trenchard, assisted by the president of the Institution, Mr. J. S. Highfield, and the senior vice-president, Dr. W. H. Eccles.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by MESSRS. MEWBURN, ELLIS & CO., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

COMPLETE SPECIFICATIONS.

172 036 MARKS, E. C. R. (LANGGUTH AND HAAR). Electric heaters for heating liquids. (21/5/20.)
172 041 CREED AND CO., LTD., and LENAGHAN, T. Electro-magnetic relays. (3/6/20.)
146 336 CHAUVEAU, L. L. E. Automatic switch for distant control. (3/4/19.)
172 055 GLASER, W. H., and GLASER, LTD., W. H. Electric current regulating devices. (23/7/20.) (Cognate Application 23 650/20.)
172 069 GRILLETTE, L. Sparking plugs for internal combustion engines. (6/8/20.)
172 088 BISHOP, G. A., and CHADWICK, R. A. Electrically-driven motor wheels for automobiles and other road vehicles. (25/8/20.)
172 091 GELY, E. L. Insulating chain for electric transport lines. (25/8/20.)
152 690 FILIPPO, H., LELY, D., JUN., and NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN. Electric discharge lamps. (27/8/19.)
165 760 WILSON WELDER AND METALS CO., INC. Electric arc welding systems. (26/6/20.)
172 102 SIMPLEX CONDUITS, LTD., and MCLOUGHLIN, H. F. Electric switches and enclosure boxes therefor. (30/8/20.)
172 104 FROST, R. J. Electric water-heater. (30/8/20.)
172 105 MARKS, E. C. R. (HORN, J. A. L.). Telegraphic receiving and transmitting apparatus. (30/8/20.)
172 112 WALL, T. F. Means for limiting change of speed in alternating current generators. (31/8/20.) (Cognate Application 13 971/21.)
172 122 MEDWAY, E. M., SMITH, E. C., and MEDWAY, A. S. Stopping or slowing of electric motors. (1/9/20.)
172 127 MACRORIE, A. K., AIREY, H. MORRIS-, and SHEARING, G. Valve transmitters and receivers for wireless telegraphy and telephony. (2/9/20.)
172 131 METROPOLITAN-VICKERS ELECTRICAL CO., LTD. (WESTINGHOUSE ELECTRIC AND MANUFACTURING CO.). Automatic electric sub-station systems. (3/9/20.)
150 958 KREMENEZKY, J. (Firm of). Electrolytic rectifier cell. (14/3/18.)
172 153 ROYCE, F. H. Electrical turning-gear for starting internal combustion engines. (15/9/20.)
172 167 SOC. ANON. DES ANCIENS ETABLISSEMENTS HOTCHKISS ET CIE, and AINSWORTH, H. M. Starting and lighting systems for use on motor vehicles. (25/9/20.)
172 170 DAVIES, D. R., and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Electrical switch gear. (28/9/20.)
172 186 SIEMENS BROS. AND CO., LTD., and SIEMENS, A. Automatic and semi-automatic telephone instruments. (15/10/20.)
172 187 ERIKSSON, E. G., and JONASSON, K. G. Electric indicator boards and the like. (18/10/20.)
164 705 MEISSNER, O. Sparking plugs. (11/6/20.)
172 192 MILLER, L., and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Electrically driven planers and the like. (25/10/20.)
157 721 BRITISH THOMSON HOUSTON CO., LTD. Braking systems for electrically driven vehicles. (25/3/18.)
172 246 SCHULZE, O. Magnetic control mechanism for liquid-raising apparatus. (17/2/21.)
160 459 DUTEIL, E. Electrolytic device for increasing the speed of ships. (16/3/20.)
161 955 ALLMANNA SVENSKA ELEKTRISKA AKTIEBOLAGET. Arrangement of neutral point resistances for electric high-tension transmission systems. (16/4/20.)
165 426 SOC. FRANCAISE RADIO-ELECTRIQUE. Electro-magnetic wave-receiving arrangements. (3/11/16.) (Divided Application on 146 204.)
172 267 HAILWOOD, E. A. Incandescent electric lamps. (25/8/20.) (Divided Application on 24 597/20.)

APPLICATIONS FOR PATENTS.

May 15, 1922.

13 588 C. O. OLSON. Wind-driven electric generators.
13 595 G. FORNACA. System of regulating voltage of electric generators.
13 601 V. E. RICHARDS. Primary cells.
13 602 V. E. RICHARDS. Apparatus for forming depolarizing element of primary cells
13 627 A. BUSHELL. Electric light fittings.
13 640 METROPOLITAN-VICKERS ELECTRICAL CO. Flexible couplings for shafts.
13 641 METROPOLITAN-VICKERS ELECTRICAL CO. Electric protective systems. (24/5/21 U.S.)
13 647 R. C. KAY.
13 649 IGRANIC ELECTRIC CO. (CUTLER-HAMMER MANUFACTURING CO.). Pressure regulating devices.
13 657 A. G. T. CUSINS. Reduction of disturbing effects of atmospherics in wireless signalling.
13 662 J. C. LINCOLN. Electric machines. (13/5/21 U.S.)
13 670 H. MACE. Electric engines.

May 16, 1922

13 707 J. W. STEVENS. Electrically illuminated devices.
13 726 J. D. MORRISON. Electrodes for welding.
13 746 C. F. ELWELL, LTD., and B. E. G. MITTELL. Wireless telegraph transmitters, etc.
13 747 C. F. ELWELL, LTD., and B. E. G. MITTELL. Thermionic valves.
13 748 RADIO COMMUNICATION CO. and J. SCOTT-TAGGART. Continuous wave transmitters.
13 749 RADIO COMMUNICATION CO. and J. SCOTT-TAGGART. Thermionic valves, etc.
13 750 J. SCOTT-TAGGART. Radio communication, etc., signalling.
13 751 EFANDEM CO., J. EATON and A. H. WILLIAMS. Electric hand lanterns.
13 762 J. B. BOLITHO. Contacts for relays.
13 763 J. B. BOLITHO. Wireless and wired wireless telegraphy and telephony.
13 779 BRECKNELL, MUNRO AND ROGERS and H. J. ROGERS. Trolley poles.
13 794 E. J. CLARKE. Electrodes for electric welding.
13 795 METROPOLITAN VICKERS ELECTRICAL CO., A. STUBBS, and J. F. PERRY. Electric mining plant.
13 811 PHILIPS GLOEILAMPENFABR, E. OOSTERHUIS, and G. HOLT. Leading in conductors for vitreous material.

May 17, 1922.

13 902 R. S. CLAY. Transmitting pictures by telegraphy.
13 904 R. O. KING. Electric ovens, etc.
13 905 BRITISH L. M. ERICSSON MANUFACTURING CO. and W. M. CROWE. Telephone instruments.
13 908
13 912 M. A. PERSSON. Electric switch (2/6/21 Sweden.)
13 913 R. T. SMITH and R. C. BOOKLESS. Wireless systems and apparatus.
13 917 EVERSHED AND VIGNOLES, and G. B. ROLFE. Magneto electric generators, etc.
13 918 EVERSHED AND VIGNOLES, and G. B. ROLFE. Electric testing instruments.
13 925 B.T.H. CO. (G.E. CO.). Electric control systems.
13 926 B.T.H. CO., A. R. YOUNG, and E. G. PARROTT. Terminals or connections for electric conductors.
13 945 J. SCOTT-TAGGART. Radio communication, etc., signalling.
13 956 AUTOMATIC TELEPHONE MANUFACTURING CO., S. R. SMITH, and P. N. ROSEBY. Receivers for telephones, etc.
13 957 AUTOMATIC TELEPHONE MANUFACTURING CO., Telephone systems. (23/5/21 U.S.)

May 18, 1922.

13 967 W. J. BIRNIE. Locking device for electric lamps, etc.
14 004 AUTOMATIC TELEPHONE MANUFACTURING CO. Automatic switches. (23/5/21 U.S.)
14 009 BUREAU D'ORGANISATION ECONOMIQUE. Fan device for electric transformers, etc. (17/5/21 U.S.)
14 021 SIEMENS BROS. AND CO., H. A. E. EASON. Incandescent lamps.
14 022 SIEMENS BROS. AND CO., J. E. COLLYER, and E. A. PETITHORY. Selecting devices for telephone systems.
14 030 B.T.H. CO. Radio receiving systems. (18/5/21 U.S.)
14 038 H. A. GILL (VIGILANT AUTOMATIC FIRE ALARM CO.). Thermostat for electric fire alarm systems.
14 040 J. E. F. YOUNG. Synchronous recording and reproduction of sounds and moving pictures.
14 042 GENERAL ELECTRIC CO., LTD. Incandescent lamps. (19/5/21 Germany).
14 043 C. J. COLEMAN. Transmission of messages through cables having high electrostatic capacity.
14 049 E. G. F. SWANGREN. Electric ignition for oil fuel.
14 050 METROPOLITAN-VICKERS ELECTRIC CO. and H. FAWCETT. Operating gear for electric switches, etc.
14 052 SOC. DES ACCUMULATORS ELECTRIQUES ANC. ETAB. A. DININ. Batteries. (6/7/21 France.)
14 064 BRECKNELL, MUNRO AND ROGERS, and A. M. WILLIS. Insulators.
14 059 H. LEITMER. Accumulators, etc.
14 083 E. SCHATTNAR. Electric starting switches.
14 088 CLARKE, CHAPMAN AND CO., and R. C. HARRIS. Electric control gear.

May 19, 1922.

14 120 W. TRAVIS. Electric melting furnaces.
14 121 W. H. WILSON. Attachment of picture projecting apparatus to electric hand lamps, etc.
14 132 C. S. GOODE. Wireless aerials.
14 182 S. G. FROST. Thermionic valves, etc.
14 189 V.M.L. EXPERIMENTAL, LTD., F. L. J. JOHNSON, and O. D. LUCAS. Electric primers and vent sealing tubes.
14 190 F. ALDENDORFF. Electric relays.
14 193 B.T.H. CO. Signalling systems. (20/5/21 U.S.)
14 196 A. M. KEAYS and F. PATON-MOORE. Utilizing parts of gramophone, etc., for wireless telegraphy or telephony.
14 198 AUTOMATIC TELEPHONE MANUFACTURING CO. Telephone systems. (25/5/21 U.S.)
14 203 H. W. F. IRELAND and O. D. LUCAS. Electric horns.
14 204 G. ELLISON and H. BAMFORD. Jointing devices for electric cables, etc.
14 205 G. ELLISON and J. ANDERSON. Oil insulated electric switch gear.
14 210 BENJAMIN ELECTRIC, LTD. Electric outlet and fixture support. (20/5/20 U.S.)
14 211 BENJAMIN ELECTRIC, LTD. Electric outlet and fixture support. (23/6/21 U.S.)
14 212 BENJAMIN ELECTRIC, LTD. Electric outlet and fixture support. (22/8/21 U.S.)
14 219 ELECTRO-MECHANICAL BRAKE CO., E. M. TAUNTON, and G. N. CADBURY. Undertrucks for tramcars, etc.
14 224 GES. FUR DRAHTLOSE TELEGRAPHIE. Arrangements for multiplying frequency of alternating current. (30/5/21 Germany.)
14 225 GES. FUR DRAHTLOSE TELEGRAPHIE. Antenna systems. (27/5/21 Germany.)
14 226 GES. FUR DRAHTLOSE TELEGRAPHIE. Reception of wireless signals. (27/5/21 Germany.)

May 20, 1922.

14 234 H. E. FOARD. Accumulators, etc.
14 264 BRITANNIC ELECTRICAL CO. Diaphragm horns.
14 283 L. A. H. DAVIS. Apparatus for electrically heating water.
14 298 D. MACADIE. Electric measuring instruments.
14 299 B.T.H. CO. Variable current generators. (20/5/21 U.S.)
14 300 B.T.H. CO. and A. P. YOUNG. Sound producing devices.
14 321 G. D. BROOKS. Electric circuit fittings.
14 328 BARRITE, LTD., and F. FERNIE. Insulation of electric conductors.
14 330 A. S. BEWLEY. Telephones, phonographs, etc.

Prices of Metals, Chemicals, etc.

TUESDAY, MAY 30.

		Price.	Inc.	Dec.
Copper—				
Best Selected	per ton	£66 5 0	10s.	—
Electro Wirebars	,,	£71 0 0	£1	—
H.C. Wire, basis	per lb.	0s. 10 7/16d.	1/8d.	—
Sheet	,,	0s. 9 5/8d.	3/16d.	—
Phosphor Bronze Wire (Telephone)—				
Phosphor Bronze Wire, basis	per lb.	1s. 2 7/16d.	1/8d.	—
Brass 60/40—				
Rod, basis	,,	7d.	—	—
Sheet, basis	,,	9d.	1/4d.	—
Wire, basis	,,	10d.	1/4d.	—
Pig Iron—				
Cleveland Warrants	per ton	£4 15 0	—	—
Galvanised steel wire, basis 8 S.W.G.	,,	£18 0 0	—	—
Lead Pig—				
English	,,	£26 0 0	—	—
Foreign or Colonial	,,	£25 0 0	2s. 0d.	—
Tin—				
Ingot	,,	£151 2 6	10s. 0d.	—
Wire, basis	per lb.	2s. 0 3/4d.	—	—
Aluminium Ingots	per ton	£100 0 0	—	—
Spelter	,,	£28 2 6	17s. 6d.	—
Mercury	per bottle	£12 10 0	—	—

Sulphur (Flowers)—Ton £10 15s. *Sodium Chlorate*—Per lb. 3 1/4d.
,, (Roll-Brimstone)—per ton £10 15s. *Sulphuric Acid* (Pyrites, 168°) per ton, £9.
Sodium Bichromate.—Per lb. 5 1/4d. *Copper Sulphate*.—Per ton £26 10s.
Boric Acid (Crystals). Per ton £60.
Rubber.—Para fine, 10d.; plantation 1st latex, 7 1/2d.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd., and the rubber prices by W. T. Henley's Telegraph Works Company, Ltd.

The Editorial, Advertisement and Publishing Offices of "THE ELECTRICIAN" are at 8, Bouverie Street, London, E.C. 4. Telegrams: Benbrotric, Fleet, London. Telephone: City 9852 (5 lines).

The subscription to "THE ELECTRICIAN" is £1 5 0 per annum in the United Kingdom and £1 10 0 per annum Abroad. Advertisement Rates can be obtained on application to the Manager. Advertisement copy and blocks should be received on the Friday preceding dtate of publication.

ESTABLISHED 1861.

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

Electrical Engineering, Industry, Science and Finance.

No. 2299. [Vol. LXXXVIII. No. 23.] FRIDAY, JUNE 9, 1922. Prepaid Subscription U.K., £1 5s. per ann.; Abroad, £1 10s. Price 6d.

CONTENTS.

Notes of the Week.

The Institution Summer Visit.

By judiciously mixing technology, Highland topography and social entertainment, and by enlisting the good offices of the Clerk of the Weather, the Institution of Electrical Engineers scored a distinct success for their visit to Scotland last week. Members saw something and heard a great deal more of the hydro-electric possibilities of the country, and are now in a position to form their own opinions upon the various schemes of water-power development that have been put forward. To see all these things for oneself is the first step to knowledge, and the Scottish Centre are to be thanked both for the opportunity they gave of so doing and their overflowing hospitality.

An Interesting Contrast.

The papers read during the meeting by Mr. R. B. Mitchell and Dr. Magnus Maclean respectively form an interesting contrast. The former, in describing the Dalmarnock station, showed what can be done with the modern steam station and made the prophecy that something better can be achieved. The key to economical working, he said, lies in the boiler house, where, with a steam pressure of 274 lb. and a temperature of 700° F., 6 5 lb. of water are evaporated per pound of coal consumed. Of the losses that occur, the most important are those in the flue gases, and opportunity should therefore be taken, where possible, to use these to pre-heat the air supply. Another indirect means of economy lies in a judicious expenditure on and the constant use of coal weighing equipment. At Dalmarnock, under normal working conditions, a boiler house efficiency of 74 per cent. is obtained, so that the use of these instruments is quite justified.

Flexibility in the Auxiliary Plant.

Mr. Mitchell also called attention to the need for flexibility in the auxiliary plant, a matter which has been carried even further at the new Nechells station of the Birmingham Corporation than it has at Dalmarnock, and to the need for constant and careful testing of the equipment. He gave a number of figures of cost, whence it appears that the total generating costs during April amounted to 0·26d. per unit and rather less for the whole year, the coal consumption being 10·65 lb. per unit generated. As the cost of coal is falling and other conditions will improve, there is no doubt that these figures will be reduced in future. Even so it is evident that Scotland is not lagging behind so far as generation by coal and steam is concerned.

The Hydro-Electric Problem.

Professor Magnus Maclean, however, was anxious that members of the Institution of Electrical Engineers should realise the amount of water power that there is available in Scotland for industrial purposes, and very eloquent he was. But the utilisation of this power is not purely an engineering question. The Highlands are practically depopulated, but if the water power present were developed there is no reason why commercial work should not be carried out under the best possible conditions and the national life thereby elevated, man-power restored, congestion in large centres relieved, and social conditions improved. It is a great dream which we do not wish to rudely shatter. The difficulty is, however, that the water power of the Highlands is not over large in amount and is widely scattered in smallish units. To develop it will require enormous capital expenditure, and to use it either on the spot or in the present industrial centres an expenditure equally enormous. While, therefore, we admire the enterprise of such undertakings as the Grampians Power Co.,

we feel this is a case where it will be well to hurry slowly; and for the present at least to leave development to such undertakings as the British Aluminium Co., whose processes are particularly adapted to the use of water power and to the harnessing of some of the smaller falls for supplying country houses and their adjacent villages. There is a great deal of profitable work to be done under the latter heading, and it certainly should not be neglected.

Sir Eric Geddes on Railway Progress.

THE lecture of the first Minister of Transport to the Junior Institution of Engineers, last week, though pleasantly reminiscent and retrospective in character, contained little that our readers are not already acquainted with. The address is mainly a defence of the Railways Act of 1921, and of Sir ERIC GEDDES' own policy. But although the schemes of amalgamation authorised by the Act must have effected great economies in administration costs and running expenses, so far traders and the travelling public do not appear to have gained much from the change. The wages bill of the railways has been reduced by over £25 000 000 a year, and other expenses have also decreased, but so far there have been only slight reductions in freight charges and passenger fares. In fact, it is only the railways that have gained any benefit from the legislation of which Sir ERIC seems so proud, and we are not sure that the Act, which practically confers a monopoly, is an unmixed blessing. Time alone will show. The market value of railway stocks and shares has risen more than Government securities and the best industrial shares, so that from this point of view the railway unification policy has been a success. But the charges are high enough to handicap trade and industry, and unless something more than the recent illusory concessions to the coal and iron trades are made there will be a public agitation which no Government or railway will be able to withstand.

Electrification and Motor Transport.

ON the important subject of electrification, Sir ERIC GEDDES had not much to say, though evidently he is a firm believer in electric traction and an advocate of the standardisation recommended by the Advisory Committee. He is also right to pronounce in favour of the railway against the road transport of goods. For passengers and for light parcels, the automobile is coming into favour in certain districts, especially in urban and industrial areas, and the electric vehicle can also fill a place in towns, but the railways have only themselves to thank for this competition. If they will persist in high fares, and if they refuse to take the obvious course of electrifying their suburban lines, they will lose more and more of their clients to the owners of motor lorries and charabancs, just as they did in earlier days to the electric tramway.

The Honours List.

WHILE the Honours List issued on the occasion of His Majesty's birthday last Saturday contains no more names of engineers and physicists than usual, it does at least contain two names which our readers will welcome with the heartiest congratulations. Mr. GEORGE SUTTON, the chairman and managing director of Henley's Telegraph works, receives a baronetcy, and Mr. ERNEST MONTAGUE HUGHMAN, honorary secretary of the Institution of Electrical Engineers in India, receives a knighthood. The connection with, and services, of both these gentlemen to the electrical industry are well known to readers of THE ELECTRICIAN. Sir GEORGE SUTTON represents all that is best and most enterprising on the manufacturing side, and by assisting in the foundation of the Cable Makers' Association has not only raised the standard of the products in which he is interested, but has paved the way for that closer co-operation between employers and employed which all but reactionaries desire. By his benevolence Mr. HUGHMAN has placed the industry in his debt in another, but no less certain, way. They are two representative men whom we are delighted to see recognised.

The Engineers' Dispute.

As we go to Press it seems likely that the dispute in the engineering industry is to come to an end. We cannot say that it has been settled, for no true settlement has been reached and the twin reasons that have forced the men to return to work are hopelessness and a lack of funds. But it is only fair to leaders of the A.E.U. to point out that they realised that this would be the outcome months ago, when they recommended that members should accept the terms they had negotiated with the employers. This recommendation was, however, rejected by the members as a whole. The leaders have now arranged once again to submit the proposals of the employers to the rank and file, and though it is unsafe to prophesy there seems every reason to suppose that this time they will be accepted, as they have been by all the other "forty-seven" unions except three. Even in these cases two are to re-ballot, so that the only sign of further prolonged cessation of work comes from the boilermakers. It may well be asked, what good has this dispute achieved? The answer is, none, except as affording yet another illustration of the need for the discovery of some better methods of dealing with such matters. That discovery must be made without delay, and in the meantime we hope that the long-promised trade revival will now really dawn.

Overhead Wires.

THE decision of a Divisional Court that poles and wires erected on a bank by the side of an ordinary public highway in Ipswich must be removed because their presence is a trespass on private property is disconcerting. But it is a good illustration of the difficulties undertakers have still to contend with in their efforts to extend the facilities for electricity supply. In some respects the judgment is unsatisfactory, and we hope that the Corporation will take the case to the Court of Appeal. Notwithstanding the alterations made by the Electric Lighting Act of 1909 and the Electricity (Supply) Act of 1919, the law relating to the use of overhead wires is still far from what it should be, and the obstructive tactics of some owners of land adjoining public highways are the cause, therefore, of much needless expense and delay.

The Law of Property.

IN the present case the road is on the outskirts of Ipswich, and, as ordinary underground mains would have been too expensive, the sanction of the Electricity Commissioners was sought and obtained for the erection of poles and overhead wires. Assuming that the reverend gentleman who sued the Corporation is correct in his contention that the bank is his property, no real damage could have been caused to him by the poles as he could not have used the greensward. It was a mere technical infringement of a purely abstract right, and we think, therefore, that an injunction is not the appropriate remedy,

for it may lead to some consumers being deprived of electricity supply. We should like to see a discretionary power vested in Judges which would enable them to fix a rental for the poles as in the case of telegraph and telephone poles of the Post Office. Electricity is no longer a luxury, but a public necessity, and somewhat similar legal principles should be applied to all important public services.

Alteration of Law Required.

In many districts it is not easy to say how far a public highway extends. Some good authorities assert that it stretches from fence to fence and includes the banks by the side. An ordinary highway is not confined to the metalled part or that portion kept in order for carriages and foot passengers, and consequently greensward or grassy banks at the side would usually be included. This was, apparently, the decision of the County Court Judge, but he has now been overruled, and the reverend plaintiff has been awarded 40s. for the four poles placed on the bank and 5s. for lopping a pine tree, together with an injunction restraining the Corporation from continuing the trespass. The law relating to the rights over the soil and subsoil of public highways is somewhat complicated, but with great deference we have our doubts about the legality of the present decision. We had hoped that sections 21 and 22 of the Electricity (Supply) Act would have smoothed the path of electricity undertakers and would have enabled a wider use being made of overhead methods of distribution. Apparently the change made was not so great as some hoped or anticipated, and it is clear that stronger powers will have to be conferred on the Electricity Commissioners in order to defeat obstructionist tactics and to enable supply authorities to extend with comparative freedom into rural areas.

Electrification Schemes.

We are glad to record that satisfactory progress is being made with the scheme for the conversion of the suburban lines of the South Eastern and Chatham Railways. Special meetings of the stock and share holders have been held and have approved of the application to the Ministry of Transport for an Order under the Railways (Electric Power) Act of 1903, to authorise the construction and equipment of a power station at Angerstein's Wharf, Charlton, and the laying of electric cables, etc., for the electrical operation of a number of the Kentish lines. We believe this is the first use made of the powers conferred by the 1903 Act, but we hope it will be the forerunner of many similar applications. At present the Electricity Commissioners are investigating the proposal to erect a generating station as well as the alternatives sources of power available, and we shall await their decision with interest. The actual work of construction will be carried out by a construction company which will grant leases to the railway companies of the generating station, rolling stock and equipment. The cost of construction will be raised by debentures or debenture stock of the construction company, to be redeemed by 1947 at the latest, but there is an option to redeem in 1927, 1932 or 1942 if the railway companies purchase the station, plant and equipment. The rent payable under the lease will provide (*inter alia*) the interest on the debentures or debenture stock of the construction company; the principal amount required to redeem the securities in June, 1947; a fixed dividend on the share capital of the construction company (not to exceed £10,000), and administration expenses of the construction company.

Underground Improvements.

The proposals of the Underground Electric Railways Company of London for the extension and improvement of some of the lines have also taken definite shape. The new Bill of the London Electric and City and South London Railway Companies seeks powers to enlarge the tunnel of the latter, to provide new rolling stock, and to extend the London Electric line from Golders Green to Edgware. The estimated cost is £6 000 000, and the Treasury has agreed to guarantee a loan of £5 000 000, repayable in 50 years. The London Electric and City and South London Companies will be empowered to borrow further sums of £2 250 000 and £1 250 000 respectively, and these borrowing powers may be exercised by mortgages or by the issue of Second Debenture stock carrying interest at a rate not exceeding 6 per cent. Interest may be paid out of capital during construction, the final date for which is August, 1926. The contracts for the various works have already been let, and a start will be made on them almost immediately. When completed the transport facilities of London will be greatly increased, and there will be readier means of access to South and North West London.

Secretaries of Societies and the Technical Press.

At a meeting of the Circle of Scientific, Technical and Trade Journalists, held in the Hall of the Institute of Journalists on May 30, a suggestive paper was read by Mr. Percy L. Marks on the duties of secretaries, especially those associated with scientific and technical bodies. Mr. Marks was doubtless right in assigning as two of the chief qualifications of a secretary, tact and a sense of humour. The latter enables him to be with equanimity the "slings and arrows of outrageous fortune" occasionally hurled at him by well-meaning but precipitate members of Council. In no field is the wisdom of a secretary more shown than in his dealings with the Press. One occasionally hears complaints from scientific bodies to the effect that their doings are insufficiently appreciated and imperfectly reported, or even ignored. The technical press as a whole is naturally anxious to give publicity to useful scientific knowledge, but space is limited and editors are human. The attention they can devote to a subject often depends more on the manner in which information is presented than its intrinsic merits. Secretaries who make a practice of issuing summaries of proceedings in which the salient points are clearly indicated, and selected with a view to their interest to the journal approached, will find their labour well repaid. Another point is that information should not be too long delayed. It is a great assistance to an editor to have the material in hand before the actual date of reading of a paper. For the rest we are glad to note that the Circle, whose work was naturally interrupted to some extent by the war, is resuming active operations and has appointed a small committee to review its programme for the future and prepare for the next session.

Postal Rates for Trade and Technical Publications.

We are also glad to observe that a resolution was passed at this meeting of the Circle dealing with the matter of postal rates—a subject to which we have several times drawn attention in the past. The moment is opportune for an agitation for decreased rates and we think it is generally admitted that in the past technical and scientific publications have not been generously treated, having regard to the fact that they play such an important role in the

dissemination of useful knowledge. It is also aggravating in the extreme to observe that foreign periodicals are delivered in England at a rate far below that charged to periodicals of precisely similar nature printed and published in this country. If the Circle can use its influence to get these anomalies removed it will deserve well of the public, as well as the Press. Governments have been driven by the force of public clamour to spend more on education. They seem to overlook the fact that in technical journals they have a most valuable educational medium, supported by private enterprise, that might well be encouraged by the slight concession involved in providing reasonable charges for postage.

Labour Representation on J.E.A.'s.

During the recent debate in the House of Commons on the Electricity Bill, Mr. Myers, a Labour member, again raised the question of Labour representation on Joint Electricity Authorities. There is no such provision in the Electricity Supply Act, 1919, or in any of the schemes at present drafted by the Electricity Commissioners. And there is no call for the representation of labour in the way suggested. As it is the fullest provision for dealing with all questions concerning labour is ensured by the Industrial Councils, bodies which are comprehensive in their scope both as to undertakings and employees. But if some other body were entitled to deal with questions of labour (and labour representation means nothing if this is not the object), then conflict would be sure to arise.

German Industrial Situation.

The Report on the Economic and Financial Conditions in Germany recently issued by the Department of Overseas Trade covers much ground and contains a mass of statistics and useful information. We have already published an abstract of the portions relating to the electrical industry, but we believe a review of the general industrial situation would be interesting, and so we propose to place before our readers some of the general conclusions to be deduced from the Report of Mr. J. W. Thelwall and Mr. C. J. Kavanagh. It must, however, be borne in mind that many of their figures are only approximations.

Country Fairly Prosperous.

The most striking fact seems to be that, notwithstanding the restrictions imposed during and since the war, and in spite of the reparations demands of the Allies and other difficulties, the country is in a fairly prosperous condition and there appears to be practically no unemployment. Further progress was made during the past year in the restoration of order in the country, and overseas trading relations were expanded in various directions. As the Germans are a highly trained, well-disciplined and hard-working people, this is only what might be expected, but in face of the great and continued depreciation of the mark, it is obvious that stable commercial intercourse cannot be established between Germany and other nations until the violent daily fluctuations of the rate of exchange cease. How this is to be brought about must be settled by bankers and business men, for apparently it is little use depending upon those peripatetic politicians who indulge in picnics in various parts of Europe.

Temporary Advantages of Depreciated Mark.

The fall in the mark is attributed (*a*) to the large issue of paper money (on December 31 last the total was 121 964 200 000 paper marks, compared with 5 500 000 000 marks in 1914); (*b*) to the necessity of purchasing large amounts of foreign currency beyond that which is secured in the ordinary way of trade; (*c*) to international gambling in marks; and (*d*) to the reparation demands of the Allies. No doubt there are other causes which have contributed to the depreciation, and it is highly expedient that all these should now be investigated in a rational, businesslike way, so that Germany may resume her place in the comity of nations, and so that this country and other industrial nations shall not suffer through the effects of the depressed mark. It is clear that Germany has been able to attract to herself during the past year a large part of the world's trade in manufactured goods owing to the low rate of the mark. Not only has she returned to her former overseas markets, but she has opened up new ones; she has largely reconstructed her mercantile marine by means of paper marks, and the ships can earn freights paid in gold; the low mark has saved her from the burden of unemployment, and it has enabled her manufacturers and exporters to re-establish foreign balances, because they were able to sell their goods and thus obtain foreign currency and supplies of raw materials.

Large Capital Issues.

During the past year the amount of capital issued by new and existing companies reached the large total of 25 907·36 milliard marks, against 8 803·77 milliard marks in 1920, so that apparently there was no shortage of capital for new enterprises or for the expansion of old businesses. A large portion of the increases in capital was required to meet the higher expenditure caused by the inflation, but it would seem that the country cannot have been unduly burdened with taxation when such a large sum was found for industrial and commercial undertakings. Incidentally, it may be noted that the electrical industry and gasworks, the metal and machine trades and foodstuffs absorbed the largest amounts of fresh capital.

Fuel Situation Improved.

The coal and fuel situation has greatly improved. The science of fuel improvement is being energetically pursued by research into the chemical components of coal and lignite, particularly for the extraction of oils, and by the utilisation of the utmost calorific value by new firing methods, especially for lignite. It is stated that the result will be a great reduction of Germany's dependence on coal and oil imports. Another important factor in the situation is the great development of electric power, first by the erection of generating stations on lignite mines where the coal is fed straight from the mine into the boilers, and secondly by the development of water power. The vast schemes for the erection of hydro-electric stations will probably take a decade to complete, but each year should see substantial progress and easier fuel conditions for the country. British engineers will watch this activity with sympathetic interest, for the results obtained may have valuable lessons for the supply industry of this country. At all events, it would appear as if some of the difficulties created by the war would be turned to the economic advantage rather than to the detriment of Germany, and the ultimate result will probably be greater industrial capacity and cheaper production.

Rhenish Electricity Tariffs.

One of the appendices to the Report contains an interesting table of tariffs for large power consumers of the Rheinisch-WestphalischeElektricitätswerke, which shows that manufacturers enjoy the great advantage of a very cheap supply. The basic price for low voltage supply ranges from 14 pfg. per kWh for 700 units or under per month to 8·5 pfg. for 8 000 units; the high tension supply tariff ranges from 11·5 pfg. per kWh for 1 000 units to 6 pfg. for 50 000 units a month, but rebates are granted on these rates ranging from 7½ per cent. for 750 to 1 000 working hours per year to 25 per cent. for 2 750 hours. The basic prices are varied according to the price of coal. For high tension supply the increase amounts to 0·3 pfg. per kWh per 10 tons for each increase in the price of 10 tons of coal over 160 marks per 10 tons, Nut Coal III or IV at Coal Syndicate price and delivered power house being taken as the basis. No rebates are allowed on these increases. It is clear that there are few parts of the world where such a cheap supply of electricity is available and this will no doubt assist German manufacturers in keeping down costs and in competing with other industrial countries in foreign markets.

The Position of Foreign Trade.

A large portion of the Report is devoted to an examination of Germany's imports and exports, though, owing to the incompleteness of the figures, and to the fact that values are given in paper marks, no reliable conclusions can be drawn. However, it is clear that substantial progress was made, though it is to be noted that an export of about 20·6 million metric tons in 1921 brought a smaller return than 19·8 million tons in 1920, when the mark was much higher. There was also an excess of exports over imports of 848 000 000 marks, but the total quantity of exports was only 27 per cent. of the figure for 1913. The value of British exports to Germany was £40 700 000 (against £51 100 000 in 1920), and the imports from Germany only £20 550 000 (against £30 300 000). The exchange is taken at 405·33 marks to the £ in 1921 and 215 marks in 1920. The quantities would have been a more reliable guide than the values, but it is stated that Great Britain furnished 13·8 per cent. of German imports in 1921, compared with 11·5 in 1913; and absorbed 8·3 per cent. of Germany's exports, against 16·2 per cent. in 1913.

Germany's Large Imports.

During the year Germany imported large quantities of cotton and copper from the United States, and her exports to America were only about one-fifth in value of her imports. In regard to Canada also the situation is somewhat similar, Canadian exports to Germany being more than twice the value of those of 1914, her imports from Germany being only about one-seventh of pre-war figures. On the other hand, Germany's trade with Italy, Holland, some of the Baltic and Balkan States, China, Japan and the Dutch East Indies is greater than in pre-war times, and there is a steady expansion in business with Sweden, India, Egypt, Spain, South America and elsewhere. Altogether we cannot help feeling admiration for the manner in which the Germans seem to have surmounted most of their difficulties. Energy, skill and experience have been expended in repairing their losses, and a large measure of success seems to have attended their efforts. Plant and factory equipment have been largely renewed out of reserve funds, thus placing them in a better position to compete in the world's markets.

Iron and Steel Trades.

Mr. C. J. KAVANAGH'S contribution on the iron and steel and allied trades makes interesting reading; but a good deal of what he states concerning Germany's losses of iron ore and coal through the Peace Treaty is now ancient history, and many of his figures can only be rough approximations. It appears that the Saar producers of iron and steel now find themselves unable to compete with the Rhineland producers owing to the payment of wages, coal and transport in French currency, and the Lorraine ore fields and blast furnaces are also suffering from acute depression for similar reasons. The German industry was helped by the inflation of the currency, the absence of large stocks of raw materials, cheap fuel, power and labour, and by internal reconstruction schemes. The coal strike in England also deflected many orders to Germany, and the result was that business was good and employment brisk, especially since the great depreciation of the mark set in. This general condition of affairs is not, however, healthy; and the plenitude of orders has enabled exporters to adopt the procedure of invoicing in foreign currency. The movement towards the consolidation of interests and the fusion of companies has continued, and the Report gives an interesting review of the most important groups, together with tables of prices, outputs and wages.

Labour and Wages.

Notwithstanding adverse conditions, the attitude of Labour towards production has so far been most exemplary, and to this must be attributed the steady progress made in the past year. The German workman seems to have a higher sense of discipline and is more easily controlled than other workers. The disputes which arose were readily settled; the extreme element seems to be smaller and to have less influence than in other countries, the result being that the output per man is now said to be almost equal to that attained before the war. During the first half of the year there was a gradual upward tendency in wages, owing to the increase in the cost of living, and the latest reports show that there has been a further sharp rise in the price of foodstuffs, with a rapid slump in the purchasing value of the mark. These factors will have a most important influence upon the future attitude of the workers; and as prices are likely to rise still further, Germany may not much longer enjoy that comparative industrial peace which has helped her during the year. Generally speaking, the working hours are longer than in this country; and as the result of the collapse of the strike of the South German metalworkers, ten hours a day are to be worked in future. There is a similar tendency in other trades, owing to the pressure of economic conditions, and this will undoubtedly react unfavourably upon the trade and commerce of other countries, but especially upon the export of goods.

As Germany is not yet in the League of Nations, there is no direct means of controlling the length of the working day in that country, but we venture to suggest to the leaders of Labour in this and other countries that it is most desirable to find means of eliminating the extreme competition of German workers who put in ten, twelve or more hours a day. The question of the length of the German working day and the stabilisation of the mark are two urgent problems upon which employers and workers in this country might profitably co-operate in finding solutions, for it is upon the right treatment of these that the future of both as well as the prosperity of the country depend.

Wireless Telegraphy in the Mercantile Marine.

By F. J. CHAMBERS. M.Inst. Radio E.

At the date of the Armistice the wireless arrangements in the British Merchant Service were abnormal in relation to what was requisite for ordinary commercial requirements. Under the Defence of the Realm Act, all vessels of any size, even coasting vessels, were called upon to carry installations, and sufficient operators to maintain a constant watch, day and night. There was actually only one company in a position to equip merchant steamers, and ship owners were obliged to make the best bargain possible under the circumstances. The standard arrangement was a contract for hire, maintenance, and the supply of operators, covering a term of ten years from the date of installation.

Meanwhile, the famous master patent, by virtue of which, assisted by Government Regulations, an effective monopoly had been achieved, had completed its term. Two new companies were registered for the supply of wireless apparatus, and a third company revived their wireless department, and re-entered the market.

A Monopoly Undesirable.

There was at this time a growing feeling amongst ship owners that a monopoly was not desirable, more especially in view of the fact that it was obligatory to carry the apparatus. It may be said that the first evidence of this was the decision taken by the Cunard Steamship Company to make trials of the other apparatus offered in order to ascertain what alternative service could be obtained. Two sister ships were selected, and the masts slightly heightened so as to represent the conditions obtaining in the average cargo steamer. A 1½ kW quenched spark set was installed on board one steamer, with a crystal receiver which could be used alone, or in conjunction with a three-valve "note amplifier." In the other vessel a 1½ kW, high-note frequency "rotary spark" transmitter was installed, with a single valve receiver which could be used in combination with a two-valve "note amplifier." Through the good offices of the Post Office authorities, arrangements were made by which the station at Valentia, on the south-west coast of Ireland, assisted in the trials. On account of these being carried out upon different occasions by the individual ships, night comparisons were considered misleading, and the actual tests were strictly confined to the periods between one hour after sunrise at the westerly station, and one hour before sunset at the easterly. Test messages were transmitted at frequent intervals as the vessels approached the point where communication was just possible. It was the best means of comparison which could be devised for vessels on their ordinary trade voyages.

Results of Official Tests.

The actual results are given in the following table :—

Main Sets	1½ kW quenched spark transmitter, crystal detector, 3-valve amplifier	1½ kW rotary spark transmitter, valve detector, 2-valve amplifier
Maximum range without amplifiers ..	358 nautical m. (on reduced power)	355 nautical m. (on full power)
Maximum range with full amplification..	553 nautical m.	584 nautical m.
Emergency Sets ..	Hammer break induction coil, quenched spark, crystal detector	Wilson induction coil, plain spark, valve detector
Maximum range with Valentia, no amplification	169 nautical m.	234½ nautical m.

The above distances were calculated as arcs of great circles. Night ranges would be approximately double the above figures.

Comparisons of the Apparatus.

It will be seen that the crystal receiver set gave as good results as the single valve arrangement. The superiority of the latter used in conjunction with a note amplifier was pronounced, and may be partly due to an advantage in applying the more prolonged impulses permitted by the grid leak method of rectification.

Measurements of the respective aerial currents with a specially calibrated Fleming high-frequency thermo-ammeter indicated a ratio of the order of 11 to 7, for equivalent d.c. input, in favour of the quenched spark set, both aerials being identical in height and form. The trials were therefore considered inconclusive as regards the relative transmitting ranges of the two stations. The obvious indication was that less "quenched spark" transmitting power could be installed for the same results ; accordingly, a ½ kW set was substituted for the 1½ kW transmitter, and the amplifier retained. Subsequent observations over a prolonged period showed that the substitution was quite justified. Similar experience of the same character was obtained on board s.s. "Kaiserin Auguste Victoria," fitted with a modern amplifier receiver, and a ½ kW quenched spark transmitter. This vessel, which handled heavy traffic, showed that she was able to hold her own with steamers employing higher powered transmitting apparatus, and similar receivers.

The Need for Amplifiers.

It therefore became apparent, very early, that "cargo boat" service with modern coast stations could be maintained, under practical conditions, with less costly apparatus, provided amplifiers were employed. But the case of large and fast Atlantic liners had to be specially considered. The volume of traffic to be handled is considerable ; the atmospheric conditions extremely bad at the time of year when traffic is heaviest ; and the jambing and congestion very serious matters. An important step towards improving this class of traffic was taken by the Marconi Company C.W. valve plant of 3 kW. was added to the installations on board the principal liners. This resulted in an immediate relief of traffic congestion. The daylight transmitting range was very considerably increased, and, by the adoption of a special wavelength, additional terminal coast stations could be operated independently of spark traffic.

Overcoming Atmospherics.

Atmospheric troubles proved much more severe on the longer wave adopted, and it soon became clear that, if a direct telegraph service in the true sense was desired, the only solution lay in using higher transmitting power.

Accordingly, the s.s. "Caronia" was equipped with a 10 kW "Elwell-Poulsen" arc, in addition to the usual 1½ kW spark set. As it was the first occasion when a large arc of the kind was called into service on board a British vessel, the first experience was valuable. Early trials indicated that there was room for improvement, more especially in connection with the means for providing the "atmosphere," and in eliminating the spacing wave. The objection to the latter was principally the jambing caused in oscillating the arc after a period of rest, which involved a certain amount of interference with other traffic. These troubles were surmounted by introducing a special form of alcohol vapouriser, which was kept operating by a current in a heating element during the intermittent periods when the arc was not required ; and by the adoption of a certain form of back shunt circuit which involved no breaking of the aerial continuity, and consequently an absence of keying troubles. After these improvements had been introduced it was found that the installation was capable of very superior service, and direct communication with the shore stations was assured under all conditions normal to the requirements of the passengers.

Introduction of Rival Systems.

The success attending the above trials encouraged ship owners generally to instal rival systems, and there is at the present time a large and increasing number of British steamers equipped with these.

Different Commercial Methods.

Until recently, it was practically the universal custom for shipowners to hire the apparatus and make arrangements for its maintenance, and for the supply of trained operators, with the Wireless Company. An alternative system, advocated more particularly by one company, is to sell the apparatus outright, and enter into arrangements for maintenance and for supplying operators who become, temporarily at any rate, the directly-employed servants of the shipping company. As to the relative merits of the respective systems, it is still a little early to judge. But an organisation set up by any company contracting for a large number of vessels, under either system, is a strong instrument against a newcomer. It is a comparatively long and costly business to build up a service for ship owners, and, unless well supported in the initial stages, a new concern has uphill work. For this, and other reasons, it is difficult to understand why British ship owners do not make arrangements to perform the maintenance and operating services for themselves. Their collective organisation abroad is enormous, and could easily be adapted to the requirements. The advantages gained would be that any suitable manufacturer would be encouraged to enter what would then be a really open market, and shipowners would then be able to do as they chose in wireless matters. In several foreign countries it has already been recognised that the first necessity is as the writer indicates, and it should be a comparatively easy matter to co-operate with foreign organisations which are proceeding along the same lines.

The Effect of a Strike.

Shortly after the Cunard trials a strike by wireless operators, resulting in an increase of wages, gave rise to negotiations between the shipowners and the wireless companies. These were protracted, but an arrangement was arrived at eventually by which the two principal parties accepted a new form of contract. Shipowners had the option of proceeding under their old arrangements, or signing the new form. In effect, the latter gave the shipowner the right to purchase his installation, at stated times, at a price which allowed for depreciation from the date of installation. After five years from the latter date the shipowner had power to terminate at six months' notice, provided he paid compensation at agreed rates for the second period of five years, making up the original ten-year term. Further details of the arrangements were published at the time. The arrangement is equitable as regards compensation, and throws the market open to competition without undue hardship to the original contractor. A competing company must, however, frame their proposals to be still more attractive, having regard to the fact that the shipowner must take the compensation scale into consideration. The onus of the arrangement falls very much upon the new contractor. In spite of this, there is a good deal of business done, though one would perhaps prefer to see this more fairly distributed in the interests of healthy competition.

Patents and Monopolies.

The present virtual monopoly has been legitimately built up during the enjoyment of the rights conferred. It has been further supported by the work of inventors in many countries. The two words patent and monopoly are synonymous, and invention is probably a greater force in the wireless than in any other branch of industry. So long as shipping, which is the main section of the industry, remains in the hands of any one organisation, there will be comparatively little return for capital invested in the development of wireless inventions, except from the smaller markets. The inventor, whether he be here or abroad, will therefore be practically compelled to make the best bargain possible with the representative of the controlling organisation in his own country. There lies the true secret of the monopoly, and until concerted, world-wide action is taken by the parties interested in the open market, conditions will remain very much as they are. On the other hand, if there were another epoch-making development of the same importance, say, as the thermionic valve, and every manufacturer were able to exploit the invention on fixed terms, the industry would receive an unparallelled stimulus. Were such an invention to come into the hands of a " ring," it would involve a great setback to others. Two important reasons for the revival of competition in this country have been the facts that the tuned coupled circuit patent has expired and the lapse of the de Forest basic valve patent. Had either of these two master patents merely changed hands, the industry as a whole would have been no better off. The remedy for monopoly is no monopoly : a free market.

An International Wireless League.

Experience of recent years shows the vital importance of consolidating wireless interests in the principal countries. It would appear to the writer that the needs of the industry call for an " International Wireless League " ; that is an organisation which could be supported by commercial concerns, patentees, physicists, engineers, and all parties who are interested in the maintenance of the open market, and the unfettered advancement of the art. Members of the League should undertake to carry out repairs at special rates, and generally assist through their organisations, visiting foreign vessels operated by other members. Should an operator fail, through sickness or other cause, to present himself for duty abroad, an appeal could be made to a local member or representative of the League, who would arrange to meet the situation, and avoid the risk of the steamer being held up by the authorities. With regard to patents, it would be necessary, individually, to accept a principle for the good of the industry as a whole. A suggestion is that members of the League should have the option of retaining their exclusive rights in the country where they are located but should undertake to grant licenses for the exploitation of their foreign patents to any member of the League, on terms fixed by disinterested arbitration. The local branch of the League in each country might undertake to bear the cost of obtaining and maintaining certain approved patents, which, with an administration charge, could be debited to the licensees. The functions of the League could be extended, and the scheme would tend to succeed if carried out in the spirit of mutual co-operation. Fortunately, the latter should be encouraged by the evidence on record showing that the small concern, struggling alone, has generally been ousted from the shipping business in the long run, or has fallen into the hands of the " ring " organisation.

Electricity Supply in Belgium.

The demand for electricity supply in BELGIUM continues to increase, and many schemes of extension and development are projected. The Societé de l'Electricité de l'Escant, which supplies in Antwerp, has made a ten years' agreement for the supply of light and power to the docks in the northern part of the city, and arrangements are being made for extending the supply cables along the Scheldt-Meuse canal to Turnhout. A 7 000 kW generating set was recently installed by the company, and a 10 000 kW unit is being erected. Out of 152 communes in the ANTWERP province, only 62 have an electricity service, but efforts are being made to devise a scheme to cover the entire province.

The Société des Centrales Electriques des Flandres, which supplies a number of communes, and has 13 600 consumers, is negotiating with the Provincial Government for the extension of its service to a number of villages in East Flanders, and with the State Government for the supply of 2 000 kW for the radio station at Ruysselede.

A committee of three engineers is examining the merits of two schemes for the supply of electricity throughout the province of LIMBOURG. A private company's proposals have been rejected, and it is probable that the Provincial Government will undertake the supply of electricity in bulk to the whole of the communes, and erect and maintain the high tension transmission lines, leaving the work of distribution to the local communes. Already about 40 miles of overhead transmission line have been erected, over 40 miles of line are being constructed, leaving about 110 miles to complete the scheme which will entail a total expenditure of nearly five million francs.

The Radio-Telephone Broadcasting Boom.

By Prof. G. W. O. HOWE, D.Sc.

The boom that is taking place at present in the reception of radio-telephonic messages and concerts cannot but interest, and, to some degree amuse, the radio engineer; to a much greater extent it should interest the advertising agent, the manufacturer of wireless equipment, and the student of psychology. The public is periodically swept by some novelty or by the resurrection of some old and well-known form of amusement. Within recent years we have had ping-pong, roller-skating, standard bread, rag-time music, and many others. In some cases the origin of the craze is difficult to trace, but for the most part they provide eloquent sermons on the text "Sweet are the uses of advertisement." In the present case our daily papers have responded well with a regular display of catchy headlines, intriguing descriptions of the delights which await the purchaser of a receiving set, and even photographs of celebrities listening to wireless concerts.

An Eastward Course.

As in so many similar cases, the boom appears to have travelled here from the United States. Owing partly to the eagerness with which any scientific novelty is taken up in the States, partly to the greater publicity given there to all such matters, but mainly, no doubt, to the almost entire absence of Governmental restriction, amateur wireless is much more widely practised there than here. It was apparently a simple matter for any college or school or even private person to fit up a transmitting station and "blaze away" to some distant receiving station. In this country, on the other hand, and in Europe generally, the authorities have kept a much firmer hand on the situation, and only gave transmitting licenses in exceptional cases. To judge from the recently issued report of the Radio-Telephonic Committee of the American Department of Commerce, it is proposed to control more rigorously the issue of licences and the allocation of wave-lengths in the United States. It is stated that about 19 000 transmitting licenses have been granted, and that about 16 000 of these are amateur.

The Original Amateur.

Even before the war there were scattered about this country a large number of amateurs who had aerials and receiving equipment and took the time signals and weather reports from Paris and Norddeich and whatever other signals they were fortunate enough to pick up. Generally speaking, these amateurs were interested in wireless telegraphy itself and not in the weather reports and other messages received. They were content to experiment with various coils and couplings and various types of detectors, and to increase the facility with which they could take down the Morse Code signals. Since the armistice, however, a great development has taken place; the thermionic tube, with its manifold applications, has opened up undreamed of possibilities. The amateur can now receive transoceanic signals with ease and make them audible to a large audience.

A New Sense.

The crowning factor, however, has been the greatly increased probability of picking up not only Morse signals, which are, after all, very impersonal and unsympathetic, especially when conveying a message in some unknown cipher, but also spoken messages and vocal and instrumental music. Even if one has no great interest in the wireless weather or market reports, and if the music, when received, may not be very much superior to that obtainable at any hour of the day or night from a good gramophone, it seems incredible that any thinking being can know that electromagnetic waves are sweeping continually through the room in which he is sitting, carrying music and speech of which he is absolutely unconscious, without wishing to provide himself with what is virtually a new sense, enabling him to understand and appreciate the messages being carried on these invisible and scarcely-to-be-credited waves. Many people will be moved by such feelings as these to purchase a receiving set.

An Increased Sense Range.

Our senses of sight and sound are operated by means of waves; the eye is, however, only sensitive to about one octave, the ratio of the wave-lengths of red and violet being roughly two to one; the ear has a much wider range, extending to ten octaves or more. The range of wave-lengths now actually employed in radio-telegraphy is greater still and, in view of the short wave tests recently described by Mr. Franklin, can be put at about fifteen octaves. Signals are passing us continually, a large number simultaneously, any one of which we may hear by suitable adjustment of this new sense, which can be purchased for a few pounds. So long as the signals when received were unintelligible sounds, one could well ignore them, but now that they may convey songs or instrumental music or news of any kind, one may be excused for showing some curiosity to "listen-in."

Progress in America.

In America it has been suggested to use radio-telephony for broadcasting market and weather reports from a number of centres to the farmers within a given radius. In Germany, where the energies which would otherwise have been employed in developing an Imperial Chain have been concentrated on an intensive development of the internal radio network, experiments have already been made with a view to distributing information of general interest from a central station to a number of receiving stations scattered throughout the country. So far as one can judge from announcements in Parliament and in the Press, the main functions of the broadcasting stations to be licensed by the Postmaster-General are to interest and amuse the public; that is, they are for pleasure rather than business. Mr. Kellaway suggested that it might be possible to enable constituents to listen to their member's eloquence in the House. We hardly know whether to sympathise with the member or with his constituents at this alarming prospect. We are pleased to see that the matter to be broadcasted is to be strictly controlled. We were rather afraid that financial considerations would entail the listener, in the interval between two musical items, in being urged in stentorian tones to try somebody's pills.

Four Categories of Service.

The American Committee divide broadcasting services into four categories, which, in the order of importance, are as follows:—Government, Public, Private and Toll. The first is that carried out by Government departments; the second that by public institutions, universities and licensed disseminators of information and educational service; the third is that by private companies licensed to send out news and entertainment; the toll service applies to those cases in which a charge is made for the use of the transmitting station.

Even the American Committee recommend the prohibition of direct advertising and the company doing the broadcasting are limited to a statement of the name of the company. A very interesting point is the recommendation that, in view of the public demand for broadcasting, wireless telephony be not used for point to point communication, where it can be effected by other means.

Good for the Electrical Industry.

One very satisfactory aspect of the boom is that at least one branch of the electrical industry is very fully occupied, and those firms who were far-seeing enough to anticipate—or should we say cultivate?—this feverish demand for receiving sets should be reaping their reward.

The wave-lengths between 350 and 425 metres are to be allocated to the broadcasting stations, but the actual wave-

lengths of the individual stations will have to be carefully chosen, so that a receiver which is equidistant from three or four transmitting stations will be able to hear one without interference from the others. This can be accomplished by giving adjacent stations wave-lengths at the opposite extremes of the range, whilst widely separated stations, such as London and Aberdeen, may have wave-lengths differing but little.

The American Committee recommend the allocation of 150 to 275 m. to amateurs, 100 to 150 m. and 285 to 485 m. for private and toll broadcasting, 275 to 285, 484 to 495, 700 to 850, 1 050 to 1 500 and 1 850 to 2 050 m. to Government and Public Services.

Radiation from Receiving Aerials.

A difficulty that will need serious consideration is that of the radiation from the receiving aerials due to the heterodyne method of reception; although weak, this may be sufficient to cause trouble in neighbouring receivers. We note that 440 m. has been allocated as an amateur transmitting wave-length. This may prove troublesome to a receiver listening to a concert on 425 m.

A useful suggestion has been made in a recent issue of the *Wireless World and Radio Review* that a distinction should be made between those who merely wish to buy a more or less standardised receiving apparatus for listening to the broadcasting service and nothing more, and those who wish to carry out experiments and modify their apparatus from day to day. The former cannot conceivably cause any interference, and it is not difficult to understand that such a person may conceivably wonder why he should have to pay ten shillings for a licence permitting him to sit in his own house and listen to the messages being conveyed, whether he wish it or not, through the ether around him.

It is interesting to note that this new development of radio-telephony depends for its success upon what was considered its greatest defect, viz., its lack of directiveness and secrecy. Broadcasting requires approximate uniformity of radiation in every direction and ease of reception.

We conclude with the words of the Postmaster-General, "the possibilities of this service are almost unlimited."

The High Frequency Resistance of Inductance Coils.

A Scientific Paper recently issued by the Bureau of Standards contains an interesting contribution by Mr. Gregory Breit on the high frequency resistance of inductance coils. At low frequencies there is little difficulty in discovering the resistance of a coil. But at high frequencies complexities are introduced by the skin effect and by the influence of capacity. The skin effect has in general only a minor influence, but the effect of capacity, as shown by the author, is of more moment. The capacity leads to a collection of charges and a non-uniform distribution of current in the coil. Hence a special definition of resistance is needed. The definition adopted by the author is such that I^2R is the power lost in the coil where I and R are measured at the point where the E.M.F. is applied. The correctness of the formulæ derived are borne out by experiments.

Another study by the same author relates to the field radiated by two horizontal coils such as have been used in an antenna for directing radio waves upwards and assisting an aeroplane to land at times when visibility is poor. It was believed that the waves would radiate in the form of an inverted cone above the antenna, and experiment has shown this to be broadly true. The nature of the field radiated has been calculated and the currents received by a coil aerial or open antenna determined. In particular the portions of space where the signal can be heard have been studied. It is of interest to note that the signal was a maximum at an angle of 30 degrees with the vertical, for a vertical receiving coil.

On the Earth Resistance of Antennæ.*

By A. MEISSNER.

For quite a long time one of the most important problems in wireless telegraphy has been the question as to how a transmitter for high powers should be constructed. In 1911 the position was one of complete uncertainty. In England L-antennæ 1 000 to 2 000 metres in length and 50 m. in height were being built, and to these fabulous directive properties were ascribed. The Telefunken Co., on the other hand, declared in the main for the umbrella antenna, while others, again, wished to use only earth antennæ.

Experiments on Antennæ Types.

In order to provide a basis for the design of the then projected high-power German colonial stations it was therefore decided by the Telefunken Co. to carry out a long series of experiments on antennæ. These were to comprise: Predetermination of their capacity, natural vibration period and damping; effect of insulation of the metal parts from the mast and its supports; and, finally, investigation of the radiation relations. The first experiments at Nauen were supplemented by a longer series between Nauen and Jena, and the guiding lines as to design thereby established, which since then have been generally applied in the calculation of antennæ, were in the main as follows:—

1. The relation, that the radiation resistance is proportional to h^2/l^2, is true for all types of antennæ (where h=height, λ=wave-length).

2. The shape of the antenna is, for equal medium heights, immaterial over a wide range; only an L antenna is less favourable owing to the large losses in the earth with this construction.

3. The directional effect of an L antenna is practically negligible when the horizontal extension exceeds 20 per cent.

The question of how the earth resistance could be reduced remained at that time unanswered.

Efficiency and Earth Resistance.

Now this very question became of burning importance, since the efficiency of the entire antenna installation depends mainly on the earth resistance, especially in large plants. So far as the generation of electric oscillations itself is concerned, efficiencies of 70 to 80 per cent. have been obtained during the last few years. On the other hand, the effectiveness of the antenna installation has deteriorated owing to the tendency to adopt longer and longer waves, for the purpose of diminishing the absorption and the liability to interference. For even if the highest practicable masts were used, a radiation resistance of 0·1 to 0·3 O only would be obtainable with wave-lengths of 12 000 to 20 000 m.; the earth resistance, on the other hand, with these long waves would be 1·5 to 5 O. This means an efficiency of the antenna installation of only 5 to 15 per cent. It is thus evident that the whole problem of the efficiency of antennæ having large horizontal expansion can be solved by reduction of the earth resistance.

There are several ways of attaining this result. One way is to increase the antenna capacity. This expedient, however, is of restricted application in that, even under the most favourable circumstances, the resistance cannot be brought down below 2 to 2·5 O; further, in the case of unsymmetrical antennæ, the resistance actually rises as the capacity is increased.

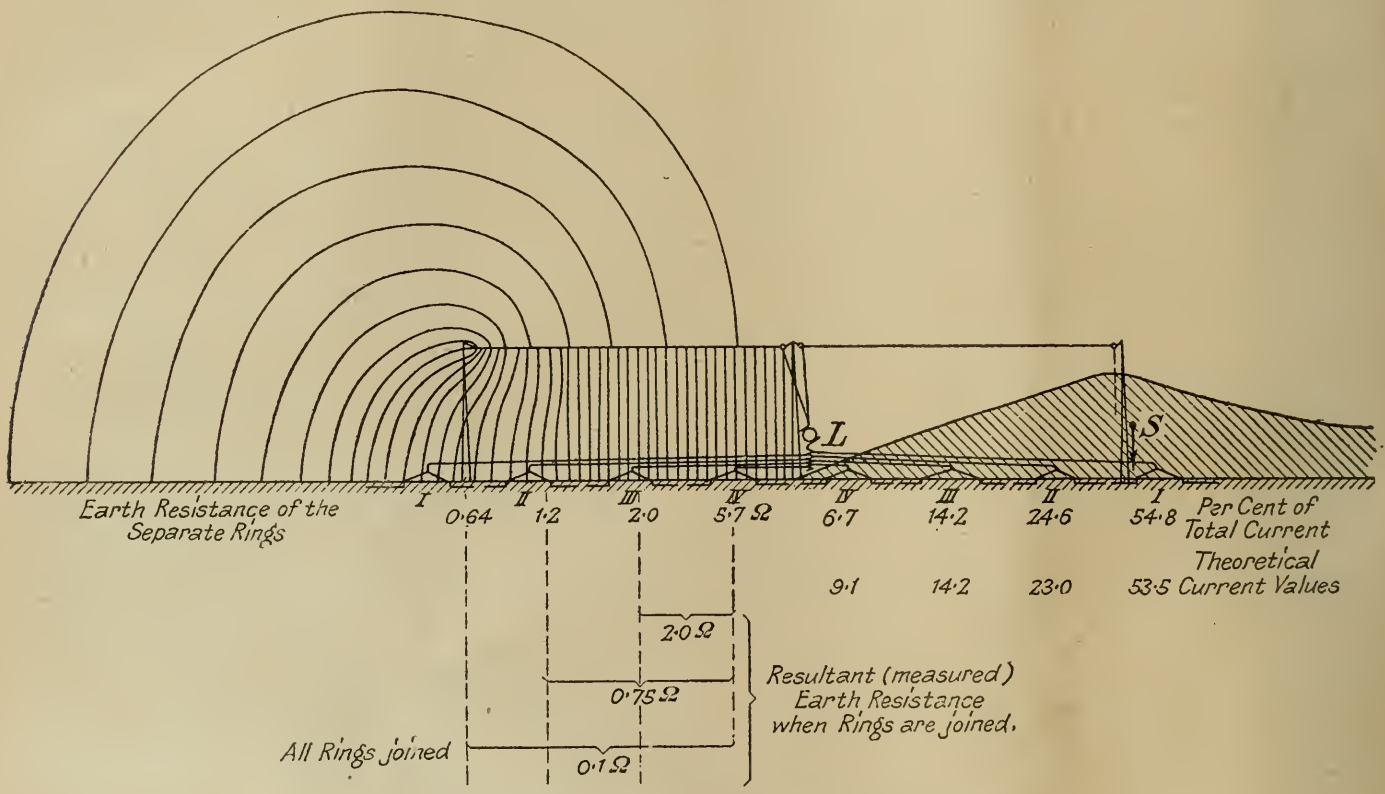
The Use of the Counterpoise.

Another way to reduce the earth resistance is to employ a counterpoise. At the Karlberg station a very large counterpoise system, utilising in its construction some 400 km. of 1 mm. copper wire, was used; in this case the earth resistance was less than 0·1 O, so that for the first time there was attained, in this way, the ideally low value desirable for a high-power station. This low value, however, is obtained at great cost, and if the same counterpoise system were to be employed at a modern really high-power station an area of 5 to 6 sq. km. would be required.

Owing to the prohibitive cost of the counterpoise construction the Telefunken Co. was forced to return to earthed installations. After long-continued experiments an arrangement was evolved by means of which similar low earth resistances can be obtained as with the large Rendahl counterpoise. The principle employed consists in taking the current

* Abstract of an article in the *Jahrbuch der Drahtlosen Telegraphie*.

from the earth's surface always at the spot, so far as possible, where the lines of force proceeding from the antenna enter the earth. In this way lengthy current paths and equalising currents in the earth are obviated—that is, the current from the transmitter is so distributed among the separate earthing places that each earth wire only receives just so much current as corresponds to the current generated by the antenna's lines of force (induced current) in the locality. If the whole surface of the ground cannot be covered with earthing conductors, the earth should preferably be placed where the greatest percentage of such induced current enters the ground. It is precisely this point which has hitherto been missed. Actually, in the case of a high-power antenna of radius 500 m. and height 200 m., the chief part of the antenna capacity, and hence the chief part of the antenna's lines of force entering the ground, lies outside the projected edges of the antenna, far from the centre of the antenna. If, therefore, the current at the mid point of the antenna is taken straight to earth, the whole of the current which enters the earth beyond the projection of the antenna



CURRENT DISTRIBUTION IN MODEL EARTHED ANTENNA.

(which means more than one-half of the whole antenna current) will have to traverse the whole length dimension of the antenna through the badly conducting earth.

Current Distribution.

The figure shows the current distribution in the case of a model actually constructed on scale of 1 : 20. The antenna was of pentagonal form with a radius of 25 m. The height was 10 m. above the ground, and the capacity 2 065 cm. Under the whole antenna and extending beyond the projection of the antenna, earths were arranged in four concentric rings, each being in the form of a star. In the first ring, counting from the outside, were 28 earthing stars ; in the second, 25 ; in the third, 15 ; and in the fourth, 5. From the first ring 18 conductors were taken to the centre ; from the second, 13 ; from the third, 8 ; and from the fourth, 2. The conductors were fastened to the central mast at about 3 m. above the ground. The earths were arranged in a ring, as mentioned, and by connecting them to the coil L—that is, by switching in more or less self-inductance in the earthing conductors—the current distribution in the separate rings could be altered at will. On so arranging the amount of self-inductance that the system had the smallest resistance, the total current was distributed over the separate rings in the proportions shown on the right-hand side of the figure. The outermost ring, it is seen, carries more than 50 per cent. of the total current. The theoretical current distribution calculated from the line-of-force diagram is indicated on the second line on the right-hand side of the figure.

Resistances of Various Arrangements.

On the left-hand side of the figure are given the measured earth resistances when the separate rings were used ; the second and third lines give the resistance when several rings are combined ; the fourth, the resistance when all the rings are connected together. It will be noticed that, when working with ring 4 only—that is, with one earth, which corresponds to, or is better than, the normal earthing arrangements hitherto used—a resistance of 5·7 Ω is obtained, a value such as is usually found for an earthed antenna of this size. When working with ring 1 only the resistance falls to 0·64 Ω. By joining all the rings a resistance of less than $\frac{1}{10}$ Ω is obtained. This resistance was measured for waves down to 400 m. in length ; above 1 200 m. it increases somewhat, and at 1 835 it reached <0·4 Ω. It can be seen from these measurements that the central portion of the antenna and earths is practically of no importance and could be omitted, were it not important for the purpose of conducting the current towards the outer edge.

It is intended to use the above-described earthing arrangement for the contemplated extension of the Nauen station. Since the antenna will in this case have a height of 190 to 200 m., the radiation resistance at a wave-length of 12 600 m. will be 0·3 to 0·33, and the coil and antenna wire resistance can be brought down to 0·3 Ω ; the total resistance of the antenna is hence 0·6 to 0·7 Ω. The efficiency of the new installation will then be approximately 50 per cent., as against 7.5 per cent. at the present time.

Metropolitan-Vickers' Edinburgh Showroom.

Splendid new showrooms have just been opened by METROPOLITAN-VICKERS ELECTRICAL COMPANY, Ltd., in Edinburgh. This is in pursuance of their plan to establish trade showrooms in the leading towns where contractors and the trade generally will find all facilities for inspecting the latest designs in domestic lighting, heating, and cooking apparatus, and of obtaining all information with regard to power installations. The showrooms are at 127, GEORGE STREET, and are therefore very central. "Cosmos" lamps and fires are attractively displayed, and a wide selection of electric kettles, jugs, hotplates, cookers, grillers, toasters, domestic irons, urns, etc., may also be seen. An extensive range of accessories is also exhibited, including the Cosmos new type connector, the "M-V" super switch plug, "Harcourt" electric fittings, &c.

Some Notes on Dalmarnock Power Station.*

By R. B. MITCHELL.

As a detailed description of the plant (see THE ELECTRICIAN, Vol. LXXXV, pp. 303, Sept. 10th, 1920) at Dalmarnock has already been published, it is advisable in this short address to deal only with some special features of the station and with some of the results which have been obtained from its working. This will be illustrated by extracts from the working figures for the whole station, test results of individual parts of the plant, and by notes on the equipment which has been provided for the oversight of the most important quantities.

Boiler Plant.

It is recognised that the boiler house provides the greatest scope for obtaining economies, and so far as the original lay-out of the station permits, everything possible has been done at Dalmarnock to help to attain high efficiency.

The following figures will indicate the results which are being obtained at present. These figures are abstracted from the working logs of No. 1 Boiler House; no attempt has been made to select a specially favourable example.

DATA AND HEAT BALANCE OF NO. 1 BOILER HOUSE.
(*4 to 7 Units in operation.*)

Average Boiler Pressure	274 lb. sq. in. gauge
Average Total Steam Temperature	700° F.
Average Temperature Feed Water, Economiser Inlet	141° F.
Average Temperature Feed Water, Economiser Outlet	274° F.
Average Temperature Flue Gases, Economiser Inlet	630° F.
Average Temperature Flue Gases, Economiser Outlet	400° F.
Average Percentage CO_2	10 per cent.
Calorific Value of Coal	10 800 B.Th.U.
Air Temperature	70° F.
Draught Over Fires (in. H_2O)	0·3 in.
Draught at Damper (in. H_2O)	1·5 in.
Draught at Fan (Ind.) (in. H_2O)	2·5 in.
Total Coal Consumed	953 580 lb.
	425·7 tons
Ashes	45·33 tons
Ashes per cent. of fuel consumed	10·65 per cent.
Total Water Evaporated	6 264 960 lb.
Condensate	6 024 000 lb.
Make up water	240 960 lb.
Make up water per cent. of total	3·85 per cent.
Lb. of Water evaporated per lb. of coal	6·5 lb. (actual)
Power consumption of auxiliaries as percentage of fuel consumed	1·68 per cent.

From the information on the above table, the following heat balance is obtained :—

HEAT BALANCE, NO. 1 BOILER HOUSE, DALMARNOCK.

	B.T.U.	Per cent.
To Calorific Value of Coal	10 800	
To Power Consumption of Boiler-house auxiliaries		100
B.T.U. Equivalent, per lb.	181	
Total	10 981	100
To Heat Transfer in Boiler	6 253	56·94
To Heat Transfer in Superheater	1 014	9·23
To Heat Transfer in Economiser	864	7·86
To Heat Transfer in Combined Plant	8 131	74·03
To Loss in Flue Gas	1 644	14·98
To Loss in Radiation	549	5·00
To Loss in Ashes, Moisture and Unaccounted for	657	5·99
Total	10 981	100·00

It is evident from an inspection of these figures that the chief source of loss is in the heat escaping in the flue gases. Provided that space is available and that a sufficiently large heat transfer apparatus can be built for a moderate capital outlay, there seems to be nothing to prevent the use of these hot flue gases for pre-heating the furnace air supply, and the gain will be represented in a more efficient heat balance, and in a saving of coal per kilowatt-hour.

Lay-out and Economy.

The lay-out of Nos. 1 and 2 boiler houses does not, unfortunately, lend itself to the installation of an apparatus of the foregoing description. In Nos. 3 and 4 boiler houses, which have yet to be built, its possibilities will not be lost sight of. The installation of automatic coal weighing machines has made it possible to obtain accurate figures of the coal consumed during each shift, without any delay. It is then a simple matter to balance this figure against the station output for the same shift. By plotting the results on a chart, a "Willans" line is obtained which is recognised as a standard to which the station engineers must aspire.

Benefit of Daily Results.

At Dalmarnock these results are plotted daily and the records have been of great benefit. This method of record-keeping would not have been possible had it not been for the weighing machines weighing the fuel as it is burned. In many modern stations it has not been thought necessary to instal these machines, but without them or some equivalent, no quick or accurate method of obtaining efficiency figures over short periods is available. Under modern boiler house conditions, where the closest supervision of the burning of fuel is imperative, the author is of the opinion that money expended on these appliances is well spent. The guaranteed combined efficiency of boiler, superheater, and economiser, is 80 per cent.

It will be noticed from the foregoing table that the boiler house efficiency attained under normal working conditions is about 74 per cent. It is expected that under better circumstances this figure will be considerably improved.

Auxiliary Services.

The method or methods adopted for driving the auxiliary plant and of using the heat energy rejected, is next in importance, if not equal, to the economics of the boiler house. At Dalmarnock, this problem has been tackled in various ways; in fact, it may seem that too many complications have been introduced. These auxiliary arrangements have been very severely criticised in an American magazine, but the diversity of auxiliary plant gives experience and data which could hardly be determined other than by trial.

All the rotary auxiliaries are electrically driven from :—

1. (*a*) Two house turbo-generators each of 500 kW capacity exhausting into open-type heaters through which the condensate is pumped;
   (*b*) Two house transformers taking power direct from the 20 000 V bus bars.
   (*c*) Nos. 3, 4, and 5 sets have auxiliary low-tension windings on the step-up transformers.
2. Nos. 2, 3, 4, and 5 turbines have steam led at low-pressure to heaters through which the condensate may be passed. Nos. 2 and 3 have surface heaters integral with the turbine and Nos. 4 and 5 external open type heaters.
3. The steam ejectors on Nos. 1 and 5 turbines exhaust into open-type heaters, and the steam driven boiler feed pumps exhaust direct into the hot well tanks. Electrically driven boiler feed pumps are also installed.

It is too early yet to state definitely which system, or combination of systems, is the most economical to use, but it will be agreed, that the operating engineers have ample means at their disposal for investigating the relative merits of the different combinations. It is certain that the integral heaters introduced in Nos. 2 and 3 sets add in a marked degree to the overall efficiency of the units, and there is much to be said also for the regular use of the house turbines.

The Ideal to be Aimed At.

The ideal to be aimed at, however, is to have sufficient flexibility in the use of exhaust steam to be able at any time to use just the exact quantity required and no more. In the past, where steam driven auxiliaries have been used without alternative, the amount of exhaust steam produced has been far in excess of requirements. This, of course, depends on the size of unit installed, and the comparatively low ratio of auxiliary power to main unit power is one of the advantages of large units over small ones.

It has been said by a critic and it will be agreed that "valuable lessons may be learned from the results observed in the operation of the Dalmarnock Station, particularly in the matter of heat balance control and the auxiliary drive. The very complexity of the design makes for exceptional flexibility in operation, and affords a rare opportunity to test out the different combinations under actual operating conditions."

All auxiliary motors are of the induction type and their reliability has been extremely satisfactory. The economic

* Abstract of a paper read before the Summer Meeting of the Institution of Electrical Engineers.

aspect is by no means so clear, and investigations are being carried out to see whether too great a price is not being paid for the obvious advantage of simplicity of A.C. motors.

Testing and Control.

Every effort has been made to measure as accurately as possible all important quantities, and for this purpose each circuit in the station has been treated separately. The quantity of coal going to the furnaces is measured accurately by automatic weighing machines, as already stated, and is, in addition, indicated approximately on each furnace. The total quantity of air for combustion is indicated, and the temperature of the outgoing air is measured accurately, so that these quantities give the chimney losses at any instant. The degree of combustion is measured by indicating CO_2 meters, one of which is placed on each furnace. The pressure of air at various points in the furnace circuit is measured by draught gauges.

For the steam circuit, the usual equipment of pressure and temperature indicators for the live and exhaust steam, together with steam flow meters, provides an indication of the boiler output, which is almost as reliable and accurate as the electrical equipment for the output of the generators. This equipment provides the staff with means for practically continuous oversight of the boiler performance.

Continuous Records.

The performance of the turbo-alternator sets is also under continuous observation, the steam consumption being measured by a Lea Recorder in the condensate circuit, while the output of the machine is measured by accurate watt-hour meters. It is interesting to note that no difficulty has been experienced in obtaining consistent results well within 0·1 per cent. at the electrical end, although of course, the question of the absolute accuracy of the results is much more doubtful.

For accurate tests on the turbines, two steel test tanks, each of 28 000 lb. capacity have been installed permanently close to the turbine room, so that very accurate measurement of the steam consumption of any set can be made when required.

The whole testing equipment has proved extremely convenient in practice. The general idea underlying the arrangement of all testing equipment has been to take the pressure, flow, and resistance, as in an ordinary electrical circuit. To illustrate the performance of the various units in the station, tabulated tests are given. These include boiler, turbine, and auxiliary plant tests.

It is interesting to note how the various instruments have gradually gained the confidence of the operators. The steam flow meter, which was looked on in the early stages as a toy, is now considered to be absolutely essential, and the temperature measurements are now quite as reliable and accurate as the pressure measurements.

Operation of Plant.

Owing to the prevailing depression and to the lock-out in the engineering trades which has been in force recently, the station output during the past few months has been much below what was expected. Dalmarnock has been carrying the whole load of the system and operating at a load factor of about 0·34 per cent.

On an output for the last month for which figures are available, the generating costs were as follows :—

DALMARNOCK POWER STATION GENERATION COSTS.

Comparison Costs for the Month of April, 1922.

	Pence per Unit Delivered.		
Operation :	Average for year.	Preceding month.	April.
Coal	0·1825	0·1707	0·1752
Coal Handling	0·0063	0·0065	0·0060
Ash Handling	0·0080	0·0084	0·0082
Water	0·0009	0·0008	0·0009
Oil and Stores	0·0037	0·0044	0·0040
Shift Wages and Salaries	0·0172	0·0169	0·0202
Maintenance and Repairs :			
Building Wages	0·0045	0·0046	0·0057
Material	0·0008	0·0007	0·0007
Engine Room—Wages	0·0070	0·0070	0·0082
Material	0·0040	0·0054	0·0061
Boiler Room—Wages	0·0113	0·0114	0·0132
Material	0·0044	0·0043	0·0056
On cost Charges	0·0078	0·0080	0·0095
Totals	0·2584	0·2491	0·2635
Totals (less Coal)	0·0759	0·0784	0·0883

Units :	
Generated	10 764 200
Delivered	10 233 203
Coal Consumed :	
Tons	9 056
Lb. per unit delivered	1·98
B.Th.U. per unit delivered	20 679
Ashes Removed :	
Tons	1 210
Percentage to coal	13·36
Make-up Water :	
Gallons per unit delivered	0·046
Number of Men Employed :	
Shift—Salaries	20
Wages	58
Time—Main and Reps.	131
Maximum Load at Station	42 200
Load Factor on Station :	
Units Delivered / Maximum Load × Hours	33·68

The cost of coal per ton in that month was taken at 16s. 6d. This figure is gradually becoming lower, and under better conditions of output and load factor, it is certain that the total cost figures will be very much improved.

BOILER TEST AT DALMARNOCK.

(Test on Single Unit.)

Normal Working Conditions.

Rate of Steaming	55 000 lb/hour
	Per cent.
Heat Transfer in Boiler	59·4
Heat Transfer in Superheater	10·6
Heat Transfer in Economiser	9·75
Heat Transfer in Combined Plant	79·75
Losses in Flue Gas	15·0
Losses by radiation	4·0
Combustible in Ash unaccounted for	1·25
	100·0
Average kW Induced Draught Fan Motor	85·5
Duration of test	4 hours on induced draught

Test results obtained on a turbo-alternator set corrected to standard conditions for the station.

Steam pressure, 250 lb. per sq. in.; temperature, 650° F.; vacuum 29·1 in.:

Load in kW.	Lb. Steam per kW-hour.
11 250	10·68
15 000	10·53
18 750	10·48

These figures were obtained without special preparations on the part of the turbine makers. The various measurements were made as accurately as possible both on the steam and on the electrical side.

Arrangements for Comparison.

In logging the station performance, an attempt has been made to get the results tabulated so that comparisons can be made readily with other plants, and at the same time give figures which the operating engineer can readily remember. In the boiler house the usual figure of lbs. water per lb. coal has been improved upon in accordance with modern practice, and this is now given as equivalent evaporation per 10 000 B.Th.U. The coal being sampled from the hoppers and tested every day, this figure becomes strictly comparable from day to day.

A summary sheet of the daily log is also compiled, the sheet being drawn out for seven days. This sheet (which is reproduced herewith) gives the daily performance compared with a standard, which represents the average results under good running conditions. The summary sheet is not for the compilation of costs : it is provided so that the operating staff may note any serious departures from the standard and take steps to rectify them.

As the all-important figure is lb. of coal per unit, the scheme suggested by Mr. R. H. Parsons some time ago in the *Electrical Review*, as referred to earlier in the paper, has been adopted. The total coal consumed, and units generated, are plotted out per shift for each month. The same is done for water. Then each month a base line is drawn on squared paper, which represents the coal per unit or water per unit, less the station losses, that is to say, if the coal line for the previous month is $C = 16\,600$ plus $1{\cdot}714\ K$, then the base line is at 16 000, and the performance of each shift is plotted against this line. If any shift shows a great departure from the base, an inspection of the summary sheet should help to find the cause of disparity.

GLASGOW CORPORATION ELECTRICITY DEPARTMENT.
DAILY RUNNING STATISTICS FOR WEEK ENDING

	Standards	4th Thursday.		5th Friday.		6th Saturday.		7th Sunday	8th Monday.		9th Tuesday.		10th Wednesday.

Total Expenditure in B.Th.U. for all Auxiliaries	3 298 302 B.T.U./hr.

The Manufacture of Ediswan Accumulators.

The EDISON SWAN ELECTRIC Co. have now been manufacturing accumulators at their Ponders End Works for over four years. The accumulators, which are of the pasted type, are manufactured according to formulæ which have proved successful during a period of over twenty years. The positive active material in the Ediswan accumulators consists of a specially evolved oxide, the physical characteristics of which give a high efficiency and long life. This is obtained without the aid of any inert substances, which not only reduce the volume of active material and consequently the capacity, but introduce matter which can be of a highly injurious nature.

The Ediswan accumulator department is self-contained, and is laid out for the carrying out of the work with a minimum of handling and transportation. The grid casting room is situated at one end of the building. Here the lead and alloys are melted in gas-heated furnaces, which are equipped with air-trunks for the exhausting of fumes, etc., from the shop. The grids are cast in moulds of special construction, so designed that the resulting grid will effectually and securely hold the paste under the most severe conditions of vibration. Above this shop is situated an acid-mixing tower from which the acid diluted to various specific gravities is conveyed to the different sections of the building by means of a system of lead pipes.

The Pasting Department.

Adjoining the casting shop is the pasting department in which are machines for the wet and dry mixing of the oxides. This process is partitioned off from the main pasting room. The machines, which are power driven, are of special construction for handling the necessary heavy quantities of lead that go to the making of the paste. After mixing, the paste is conveyed to the pasting benches, which are lead covered. Here it is applied to the grids in a manner which ensures intimate contact between the paste and grid. The plates are then subjected to a pressing process, and are then conveyed to the drying room, where they pass through a special drying process.

When the plates are thoroughly dry, they pass through to the forming room. Here there are a series of forming rows which are controlled from panels situated in an adjoining switch room. The formation process is of too complicated a nature to give in detail here, but every care is taken to ensure that the resulting plate is absolutely free from defects. On completion of this process, the plates are passed to another drying room, where they are thoroughly dried out and stored ready for assembly. The next process is the section casting and lead burning. Here the plates have the section bars either cast or burnt on according to the type of battery under construction. From this department the made up sections are passed to the assembling room, where separators are inserted, and the sections placed in their containers. A part of the assembling room is devoted to pitching in the sealed top type batteries.

The next section is the test room. Here there are four charging panels, each capable of dealing with accumulators up to 360 Ah capacity. The last stage is the packing for despatch. In the packing department, cells of all sizes and types are carefully packed for despatch to all parts of the world.

Chemical Treatment of Wood Separators.

Adjoining the main accumulator shop is an annexe in which wood separators are treated. These separators, which are made in the works, are here treated in a series of chemical baths for the removal of resin and other oily matter, which would have a detrimental effect upon the working of the battery. The raw material store also adjoins the main shop.

The Institution of Electrical Engineers.

A Successful Summer Meeting in Scotland.

The success of the summer meeting of the INSTITUTION OF ELECTRICAL ENGINEERS, which was held last week in Scotland —and there is no doubt it was an unqualified success—may be ascribed to two authorities—the committee of the Scottish Local Centre, and especially the chairman and honorary secretary, Mr. E. T. Goslin and Mr. J. Taylor; and the Weather Bureau, as represented by that much-maligned and misunderstood person the Clerk of the Weather. That to visit Scotland, and especially the Western Highlands, in early June is an adventure is well evidenced by the recommendation to those joining the expedition to take warm clothing and rain-protective devices. The Clerk of the Weather, however, saw fit to render these recommendations quite nugatory, and, except on the voyage from Fort William to Kinlochleven, the weather was dry and very warm. A party of nearly 400 took part; and though a large number of these were either local Scots or Scots once again visiting the land of their birth, there was a sufficient intermixture of Southrons to give a representative character to the whole. Many new friendships were made, a number of old friendships were renewed, many interesting places were visited, and, generally, the visit may be described as a liberal education, which we hope will be repeated in due course.

Monday, May 29.

Thanks to the courtesy of the London and North-Western Railway Company, the party from London travelled down in the comfort of a reserved restaurant car, a facility that was all the more appreciated as the weather was very hot. During the course of the day visitors from other parts of the country converged on Glasgow, and made preparations for the strenuous life of the next few days.

Glasgow and Kelvin.

Tuesday, May 30.

The first business this morning was an official welcome to the Institution by the Corporation of Glasgow. This took place in the Royal Technical College, when the LORD PROVOST (Dr. Paxton) said that it gave him great pleasure, on behalf of the Corporation and the citizens of Glasgow, to extend to the Institution a most cordial welcome. He referred to the Jubilee celebrations, and said it was fitting that in its Jubilee year the Institution should visit the city where Lord Kelvin had spent so many years of his long and useful life, and had carried out work which had made his name famous throughout the world.

The PRESIDENT (Mr. J. S. Highfield) in reply, thanked the Lord Provost for his welcome, and expressed the pleasure it gave the Institution to meet in the city associated with the labours of Watt and Kelvin.

Dalmarnock and Clyde Mills.

A paper on "The Dalmarnock Generating Station" was then read by Mr. R. B. Mitchell. He began by giving some details of the progress of electricity supply in Glasgow, the latest phase of which was the erection of the generating station at Dalmarnock, whose various features he detailed. (A full description of this station was given in THE ELECTRICIAN of Sept. 10th, 1920.) He also gave an interesting account of the working and test results obtained and replied to some criticisms which had been levelled at the station's design and performance. This portion of the paper is given in abstract on another page of this issue; but it is interesting to note here that the guaranteed combined efficiency of boiler, superheater and economiser is 80 per cent., and that under normal working conditions 74 per cent. is obtained, though it is hoped that this figure will be improved.

It will be remembered that the first section of the station is to have a capacity of 93 750 kW in five sets of 18 750 kW each; and that a feature of the station is the coal-handling and storage plant. Energy is transmitted from the station at 20,000 V by cables to various sub-stations, and an interconnection is also to be made with the system of the Clyde Valley Electrical Co.

After having heard all about the station those present (or some of them) followed Mr. Squeers' policy and went to see it. It was generally agreed that it came up to expectations.

Lunch at the City Chambers.

Subsequently the Institution was entertained to luncheon by the Corporation at that handsome building—the City Chambers.

Bailie SADLER, in proposing "The Institution of Electrical Engineers," paid a tribute to the fame and work of Kelvin and quoted Varley's well-known saying regarding the future of the Institution. Varley was a true prophet, for who could set bounds to the scope of electricity. Every advance in our knowledge of the structure of the universe—and enormous strides had been made since his day—increased the probability that electricity "embraces every operation in nature." As Varley foresaw, the specialist character of the original body was soon merged in a diversity of electrical interests. Its growth had been steady, and the Institution had fulfilled its rôle in the highest degree, in that it had provided continuously an arena wherein electrical problems of every description might be debated, new methods and ideas brought forward and discussed, and accounts of progress, both at home and abroad. placed before its members. Much of its work was pioneer work, the benefits of which the industry was now reaping.

Mr. J. S. HIGHFIELD, in acknowledging the toast, said they had to deal with far more than the application of electricity. It was being shown more and more clearly every day that the whole of the universe was made up of electricity, and they had the whole range not only of matter but of energy.

In the afternoon visits were paid to the Clydesmill generating station of the Clyde Valley Electrical Power Co., a description of which appeared in THE ELECTRICIAN, Vol. lxxxvi. p. 86, June 3rd, 1921, and to the Corporation reservoirs at Milngavie. At both places the visitors were entertained to tea.

Civic Receptions and Informal Meetings.

In the evening a civic reception was held at the City Chambers, the principal attractions being music, dancing and refreshments (these are not necessarily arranged in order of merit). The national dances of the Scots, as performed with vigour and enthusiasm by the natives, were a great attraction, and to the Southern members the more usual terpsichorean evolutions were good exercise. We think it is a tribute to the vitality of the Institution that past-presidents and members of Council were particularly active in this exercise. Surely we have nothing to fear in the future when the seniors of the profession are so youthful in both outlook and action.

It is only right that the veracious chronicler should add that many unofficial meetings took place in the lounges and smoking rooms of the various hotels, whereat the subjects discussed were not wholly technical. Considering the hour at which some of these meetings broke up they must have been interesting.

Kelvin's Lecture Room.

Wednesday, May 31.

On Wednesday morning the first business was a lecture by Prof. MAGNUS MACLEAN on "The Hydro-Electric Resources of the Scottish Highlands." Prof. Maclean is himself a Highlander and he is an enthusiast on his subject, a combination which makes for a successful lecture.

Principal Sir DONALD MACALISTER, in welcoming the Institution on behalf of the University, said he was happy to receive them in the room where Lord Kelvin had laid the foundations of electrical engineering. Minor alterations had taken place, but his spirit remained and no one would welcome more than he the great developments which had taken place in the science he had founded so well. Sir Donald mentioned that he himself had also had to do with the beginnings of electrical engineering. He had helped to correct Clerk Maxwell's "Electricity and Magnetism," and had overlooked a great many mistakes that subsequent editors had discovered.

The Hydro-Electric Resources of Scotland.

Prof. MACLEAN began by saying that one of the most far-reaching effects of the late war had been to bring the nation face to face with its own resources. For decades previously its chief concern had been the promotion of specialised industries in the large centres. Almost everything else was sacrificed to this national activity, and the lives of men were moulded to feed the fires and keep going in pitiless monotony the rattle of machinery, which was fast becoming an industrial Moloch. No doubt the age of coal and iron might have to be regarded as a necessary stage in the onward march or evolution of civilisation, but we had only to visualise the effects as we knew them to realise how far a large proportion of the working classes had been sidetracked by this industrialism.

The wonderful thing was that we had been so blind with regard to our real assets. We had erred in two ways. On the one hand, we had wasted most extravagantly many of our resources, and on the other hand we had almost entirely neglected others. In the midst of the Great War struggle we were forced by stern necessity to take stock of our resources, and our eyes were opened to new possibilities. Of the various national resources to which the attention of the Government and the people was now directed water power was dominant. Personally he was concerned with it not only as an industrial proposition, but as a means of elevating the national life, of restoring man-power, of relieving the congestion in the large centres, of resettling the people on the land, and of furnishing them with better houses, better food and clothing, and a more natural life in the country. In a word, he held that the proper use of water power in the Scottish Highlands would go far to solve some of our pressing problems and promote comfort and contentment among large sections of the population. The extent of the Highlands was 40 per cent. of Scotland, though only 7 per cent. of the population was within that area.

Prof. Maclean then described in detail the Lochaber and Grampian power schemes and said that we were now at a point of departure in our whole industrial system. The old order, black and barbaric in many features, was yielding place to new methods. We were in the midst of readjustments which heralded the dawn of a new era, and it was given to us to be pioneers in the process. For all practical purposes light, heat and power were coming more and more to be comprehended in the word " electricity," and as our coal resources were being depleted we must rely for its production in the future to a greater extent on oil and water-power and other at present undeveloped agencies.

A Babcock Afternoon.

In the afternoon members combined work and pleasure in a most ingenious fashion. At the invitation of Babcock and Willcox they joined the " Queen Alexandra," a steamer with a gallant war record, at the Broomielaw and steamed past the shipyards of the Clyde to Renfrew, whence they were conveyed by special train to the works of the company. Here they were divided into parties and conducted through part of what is the largest boilermaking concern in the world. At these works are manufactured mechanical stokers, water softeners, superheaters, coal and ash handling plants, steam and water piping, valves, structural steel work and cranes; in fact, everything for the steam side of a modern generating station, except the turbines. There is evidence enough of a thorough system of production, a splendid organisation and a general efficiency, and it was gratifying among the present industrial troubles to find so many men at work. The one drawback to the visit was the intense heat, which caused one eminent electrical engineer to enquire anxiously for the whereabout of the canteen, for, we hope, platonic reasons only.

The " Queen Alexandra " was required shortly after 4 o'clock, when tea and other liquid refreshments were in great demand as the good ship headed down the river. A most enjoyable evening was spent viewing the beauty spots of the Clyde and the famous Kyles of Bute. Much speculation arose as to the ownership of the many palatial residences on the banks, Sir Harry Lauder, as being the only Scot known to most Englishmen, being the favourite. We hear on the highest authority that most of them are hotels, another tribute to the canniness of the native. During the course of the evening dinner was served, a photograph taken, and two very short speeches of thanks and acknowledgment made by Mr. Highfield and Sir James Kemmal. The best testimonial to the success of the expedition was in the remark we overheard a member make " That if Babcock's boilers were as good as their hospitality he must really buy one." Unofficial meetings again continued until a late hour.

A Tour in the Highlands.

Thursday, June 1.

At an early hour the party set forth by special train for Queen Street Station, Glasgow, for Fort William. This journey is Scotland peptonised. First tunnels and Glaswegian suburbs. Then Clydebank, Dumbarton and shipbuilding. Then Helensburgh seaside resorts and yachting. Loch Lomond, Ard Lui, mountain and loch scenery. Then the Moor of Rannoch, Caledonia stern and wild, and once again the sea and hills at Fort William. The Institution saw all these under the most favourable conditions, the necessary technical leaven being introduced by an inspection at Tulloch of the headwaters of the Lochaber power scheme. At this point we became aware that we were in the Highlands. Pipers joined the party and their music and ceremony was a feature of the remainder of the visit.

Highland Hospitality.

Fort William was reached in the early afternoon in advance of the time table, rather to the consternation of the various hotel keepers on whom the members had been billeted. Highland hospitality is proverbial, but it is different from that to which we are accustomed in the South. One of its peculiarities is gregariousness. In other words, two beds in a room and a room-mate is the order. To those of us who have experienced worse things in the Army the prospect was one which could be viewed with equanimity, but some of the others gave the unfortunate hotel keepers a *mauvais quart d'heure*, until their desire for single blessedness had been satisfied in some way or other. Our best advice to the " Fort Williams " is that before the Institution visit them again they build a hotel with nothing but single bedrooms.

We congratulate the local hospital on their piratical instincts in arranging a dance, sweepstakes and other money-getting enterprises on the day the Institution visited their town. The results must have been most gratifying.

Kinlochleven.

Friday, June 2.

The day's work began with a sail down Loch Linnhe, past Ben Nevis, and up Loch Leven, past Glencoe to the works of the British Aluminium Co. at Kinlochleven. These works have already been fully described in THE ELECTRICIAN, and are substantially the same as at that date, except that two extra generating sets have been added. The continuous load is about 20 000 kW. A feature of the place is the model village, which is a garden city among mountain scenery. There is a general air of well being which the activities of the company do not belie. It was suggested that an International Climbing Contest might take place up to the dam, but we did not hear of any entries.

After being entertained to lunch by the British Aluminium Co., the party set sail for Oban, where the meeting officially came to an end. Most of those taking part spent the week-end in profound sleep, having thoroughly exhausted and enjoyed themselves.

Reviews.

Factory Administration and Cost Accounts. By EDWARD T. ELBOURNE. (London: Longmans, Green & Co.) Pp. xx+811. 45s. net.

The war period provided new experiences in many directions, and not the least of these was the new experience obtained in the various branches of industrial administration. Mr. Elbourne published a book on industrial administration, entitled " Factory Administration and Accounts," in March, 1914. The present volume is of a more comprehensive character than the earlier volume, and aims at a more specific purpose, so justifying the change in title to " Factory Administration and Cost Accounts."

The volume is divided into two main divisions, the first of which relates to Works Management and includes three subdivisions referring respectively to Production Control, Labour Administration, and Material Control. The second division relates to Works Accounting and includes the two subdivisions of Administrative Records and Cost Accounts. The book is prefaced with a chapter on General Administration, and concludes with a chapter on Works Routine, the latter containing a large number of specimen forms used in industrial administration. Production Control deals with manufacturing processes, production, estimating, and rate-fixing, the provision and maintenance of tools and plant, concluding with an important section on the functions of foremanship and inspection. The section on Labour Administration records in considerable detail the more important features of industrial relations, trade union agreements, and working conditions, together with systems of wage payment, the selection and training of workers, and works regulations. Material Control includes information relating to purchasing and stores organisation, and to the warehousing and the despatch of goods. The section of the book relating to Works Accounting sets out in logical sequence the important aspects of administrative records, including employment and production statistics, and stock accounting. The section on Cost Accounts comprehensively analyses the underlying principles of a system of cost accountancy.

In view of the importance in modern industry of the suitable training of apprentices and all grades of industrial workers,

and also the growing importance of industrial research, it is unfortunate that the author makes scant reference to the first subject, and practically no reference at all to the latter subject.

At first sight it would appear as though the present volume fails to include an important chapter of the author's first volume, relating to the general problem of industrial works design, and contains such information as the choice of site, and general arrangement of both buildings design and process organisation. Much of this, we find, however, is contained in a sub-section of the Works Management division of the book relating to buildings and plant, and marks a distinct advance on the matter included under this heading in the earlier volume.

An important adjunct to the text is the system of cross references that has been developed, so that when the reader has once found a particular subject through the index, he is readily referred by the marginal page references to other pages bearing on the same subject. Another important and useful detail feature of the book is the glossary appendix giving definitions of the more important terms used throughout the text.

The most obvious use of the book is as a volume of reference for industrial administrators, works managers, and persons in like positions, but the volume should refer to a much wider field than this. It provides for the student of industrial administration a most up-to-date and valuable text book, and affords the ever-increasing number of students of the human problem in industry an opportunity of becoming familiar with the more important aspects of industrial organisation.

It is important to indicate that the book is by no means academic. The author has had wide industrial experience, and during the war period practised as a works manager of a large national factory. Throughout the book discussions relate to modern methods, and enumerate details of procedure in addition to the broad underlying principles.

While no one book can exhaustively deal with the whole field covered by the subject of industrial administration, the present volume constitutes a very commendable attempt to outline the more important aspects of industrial administration. It is reasonable to expect that further volumes dealing in greater detail with the special phases of industrial organisation will be required.

A. P. M. Fleming.

The Electric Furnace. By J. N. Pring, M.B.E., D.Sc. (London: Longmans, Green & Co.). Pp. xii+485. 32s. net.

Electro-metallurgy has during the last few years developed so rapidly along so many different lines that it is a very difficult matter to cover the subject adequately in one book, and even more difficult for any one man to be able to keep his information on all the different branches up to date. Dr. Pring's book deals with a great many subjects, and he has accumulated information of great interest from a number of sources, but in many cases the information is now out of date. For instance, he publishes on p. 391 a table showing the permissible current density on different sized electrodes, which for 16 in. diameter electrodes is given as 10·7 A per sq. in. He also refers several times to the necessity of using several electrodes clamped together in steel furnaces, owing to the impossibility of obtaining satisfactory large electrodes. These statements were perfectly correct ten years ago, but fortunately the time has passed when one of the chief qualifications of an electric melter was the ability to remove large pieces of broken electrode from the furnace rapidly.

A considerable part of the chapter on electrode holders might also have been written in 1910, and in a number of other cases references are made to papers written between 1909 and 1913. Electro-metallurgy has advanced so rapidly in the last few years that most of these papers now only possess a historical interest. The information on graphitising electrodes is necessarily not very detailed, as it is to a large extent a secret process. The particulars given do not represent modern practice, and the output of 3 to 3½ tons for 1 000 H.P. units in a run of 20 to 24 hours is unduly optimistic.

We think that sufficient credit has not been given to Great Britain for the great expansion of her electro-metallurgical industries during the war. In the chapter on ferro-alloys, while numerous Continental and American works are mentioned by name, there is no reference to the fact that by 1918 a firm in Newcastle was employing over 15 000 kW in the manufacture of ferro-chrome, ferro-tungsten and ferro-molybdenum, which was sufficient to supply the whole of the very large British requirements of ferro-chrome and a considerable proportion of the ferro-tungsten consumed. Moreover, the erection of one British graphitising factory and four amorphous electrode factories, with a capacity of about 13 000 tons a year, is ignored.

The application of the electric furnace to the brass industry has been dealt with very briefly. Only four pages are given to this branch of electro-metallurgy, and the Ajax-Wyatt induction furnace, which is more widely used in American than any other type, is not even mentioned.

Several other interesting subjects have either been discussed very shortly or completely ignored. Among those which might have received more recognition are the whole subject of automatic regulation, the various types of electrode economiser, the possibilities of the new Söderberg continuous electrode process, and above all, the extent to which the war development in all electro-metallurgical branches in likely to be permanent. Information on these points would surely be of more interest than a highly theoretical consideration of the most suitable size of electrodes, which entirely ignores the relative cost of the amorphous and graphite products, the size most suitable from the metallurgical standpoint, the standard sizes available from different works and the fragility of the smaller sizes of graphite electrode.

In spite of these criticisms, we consider that the book is a valuable addition to the technical library of all who are interested in electro-metallurgy. The illustrations and plates are excellent, and a useful bibliography is included as an appendix.

W. S. Gifford.

Notes and Examples on the Theory of Heat and Heat Engines. By John Case, M.A. (Cambridge: W. Heffer & Sons, Ltd.) Second Edition. Pp. 138. Price 7s. 6d. net.

In the reviewer's student days, Prof. John Perry (of whom grateful memories) used to tell us that we were too much "spoon-fed"; then out of his kindness he used to do his best to extend the process. We cannot help feeling that this delightful little book is another step in the same direction.

We know what the present-day students will say in reply to this. We know they will point out that they are expected to learn more and still more, that so much data has been accumulated in science, and now it is proposed that they should take courses in law and economics. Probably in no distant future enthusiasts will require them to take a course in eugenics as well. However this may be, here is a little book in which is collected together all the important formulae relating to the first and second Laws of Thermodynamics, together with clearly worked out examples which will be of great help to the student who has to memorize such matters for examination purposes. It will also be of great use to many older engineers who only occasionally wish to dip into such matters.

There is very little to criticize. It seems rather a pity that the author should take the symbol I instead of the universal symbol H. It seems also a pity that he should base on Smith and Warren's Tables when Callendar's Tables now hold a practically unchallenged position. We do not feel very sympathetic towards his handling of the question of internal energy of steam. Most of the problems which he gives for this quantity can be more simply treated by dealing with the total heat. We rather pity the poor student who has to do many examples on the simple logarithmic formula for entropy based on the conception of a constant average specific heat for superheated steam. Why also should he have to do such a lot of work on reciprocating engines?

If his course at Cambridge is to be of any real help to him when he comes to deal with questions of steam in actual practice, he could not be more helped than by giving him Callendar's Tables and telling him what they mean, and how to use them. There must come a day when this sheer memory work as indicated by the science tripos questions must break down, and the division between college and the drawing office tend to disappear. In the meantime, however, we have no hesitation in recommending this book to our student friends.

W. M. Selvey.

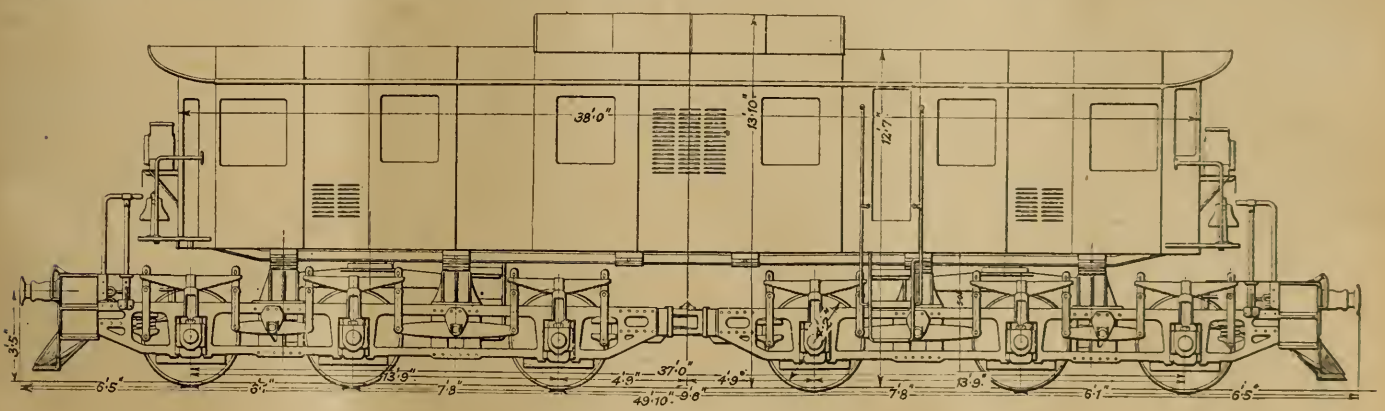
Electric Locomotives for Chilean Railways.

Work on the electric locomotives, which are being built for the Chilean State Railways, is rapidly progressing. The cabs for the first eight of the fifteen road freight locomotives have been delivered by the Baldwin Locomotive Works to the Westinghouse Electric Company for the installation of the equipment. There will also be seven shunting locomotives. The cab of the road locomotive is of the box type, carried on two articulated trucks, each having three driving axles with direct geared motors. The total weight is 226 000 lb. The locomotive will operate at 3 000 V d.c., and will be able to develop 3 200 H.P. for short periods. With natural ventilation the locomotive will deliver for one hour a tractive effort of 27 950 lb. at 22·6 miles per hour, but the continuous capacity with forced ventilation is 20 880 lb. at 24·8 miles per hour. The maximum speed is 40 miles per hour. The general dimensions and estimated weights of the locomotive are as follows :—

Dimensions and Weights.

Track gauge, 5 ft. 6 in. ; length over buffers, 49 ft. 10 in. ; length over cab, 38 ft. ; total wheel base, 37 ft. ; rigid wheel base, 13 ft. 9 in. ; height, top of rail to cab roof, 12 ft. 7 in. ; width over cab sheets, 10 ft. ; height of coupler, 41 in. ; wheel diameter, 42 in. ; weight of electrical equipment, 86 000 lb., and weight per driving axle, 37 670 lb.

The locomotives will operate over the 116-mile route between Santiago and Valparaiso, and the 28-mile branch between Las Vegas and Los Andes. The heaviest grade is 2·25 per cent. for 12 miles from Llai Llai to La Cumbre ; the maximum curvature is 11 deg. The present main line freight trains average 550 short tons, and are operated by a single steam locomotive, except on the heavy



Outline of Freight Locomotive.

12-mile grade southbound, and on a northbound grade of 6·8 miles. On these two sections a steam helper is used to maintain speeds of from 10 to 14 miles per hour. One electric locomotive will haul 770 short tons in either direction between Valparaiso and Santiago without assistance, except on the Tabon grade. On level track the speed with such a load will be 35 miles an hour. The average running speed on the Tabon grade will be 24 miles per hour. The time saved by the elimination of delay to take fuel and water and by the higher running speed will shorten the time of a trip from four to five hours in each direction.

Equipment of Locomotives.

These locomotives are equipped with Continental spring buffers and M.C.B. couplers, arranged to take attachments for chain couplers temporarily. The two six-wheel trucks are connected at the inner ends by a Mallet hinge. The bar-type cast steel side frames are outside the wheels and are connected by cast steel bumpers and cross-ties. The semi-elliptic driving springs over the journal boxes on each side are connected by equal beams, and the ends of each set of three driving springs are attached to the side frames through coil springs. The 38 ft. box type cab, including an engineman's compartment in each end and a central equipment compartment, is carried on centre pins over the midpoint of each rigid wheel base. One centre pin is restrained both longitudinally and laterally, and the other in the lateral direction only, permitting free longitudinal movement of the cab relative to one truck. The locomotives are equipped with air brakes interlocked with the regenerative brake, so that the latter may be supplemented by service application of the train brakes, if desired, without applying the air brake to the locomotive driving wheels. Current is collected by spring-raised, air-lowered pantagraphs, which are controlled by compressed air and are mechanically locked in the lowered position.

Control and Motor Equipment.

Individual switches, mounted in banks, establish the main circuit connections. Each switch is a complete unit and may be removed without disturbing adjacent switches. Compressed air, controlled by electro-magnetic valves, is used to operate the switches. For certain circuits, where no current is broken, and for low voltages, there are cam switches, which are also operated by compressed air. The cam group comprises a number of switches mounted on a single shaft, connected through a rack and pinion to a double acting air piston. Each axle is driven by a motor wound for 1 500 V and insulated to operate two in series on 3 000 V. The nominal rating of the motor is 280 H.P. at 155 A and 1 500 V. Field control is secured by two separate field windings on the main poles. The motors are geared directly to the axles with a ratio of 3·94 to 1. The gear is of the flexible type.

A motor-generator set provides low voltage power to compressors, blowers, control equipment and lights. The 3 000 V motor is a bi-polar double-commutator machine, and the continuous rating in the generator is 35 kW at 92 V. A master controller is located of each engineman's compartment to provide double end operation, the same master controller being used for both motoring and regenerative braking. This controller provides 50 control notches in acceleration, so that tractive effort variations are small, thereby permitting a smooth handling of the trains. The control provides speed combinations by varying the grouping of the motors to give one-third, two-thirds, and full speed. Field control gives three additional speeds. Transition from one motor combination to another is made by the shunting method. For regenerative braking, the main motor armatures are arranged for the same combinations as when motoring, and the motor fields are separately excited by the motor-generator set. The range of speed in regenerative braking will be from 8 to 30 miles per hour.

Shunting Locomotives.

The shunting locomotives will be the last ones to be built. The cab is of the steeple type and is carried on two swivel trucks. On each truck are mounted two motors driving direct through standard helical gears. The estimated weight is 136 000 lb. The control is arranged for double end operation. The nominal rating of the locomotive is 560 H.P. With 3 000 V, and natural ventilation, the tractive effort for one hour is 19 600 lb. at 10·6 miles per hour, and the continuous capacity is 11 400 lb. at 12·7 miles per hour. With 25 per cent. nominal adhesion the starting tractive effort is 34 000 lb. The maximum speed is 35 miles per hour. For short periods the equipment is capable of developing 1 000 H.P. In view of an expected increase in traffic the locomotives will be able to handle trains of 1 200 short tons in yards with level tracks. The trucks are of the rigid bolster equalised type with rolled steel frames located outside the wheels. A centre pin is located approximately midway along each rigid wheel base. The central cab has an engineman's stand at each end, and control apparatus centrally located and suitably protected. Buffers, couplers, air brake and control equipment are similar to those on the main locomotives, and the pantagraph is also of the same type. The four motors of the series type are wound for 1 500 V, and are insulated for operation two in series at 3 000 V. The motor has a one-hour rating of 140 H.P. at 75 A and 1 500 V. The motor-generator set, to supply power for the compressor motor, lights and control circuits, has a two part frame, each part containing two bearings in which runs a common shaft carrying two armatures, one a 1 500 V motor (insulated for 3 000 V) and the other a low voltage generator. With 3 000 V applied to the motors, the generators will deliver 22·5 kW at 92 V. The main resistance, connected ahead of all motors, is designed with ample capacity for frequent, heavy accelerations, and for a reasonable amount of emergency operation with one pair of motors cut out.

The troubles of would-be "broadcasters" already begin to manifest themselves. A Rhyl hotel licensee inquired last week at the local police court if it would be necessary to have a music licence if he put in a wireless set to intercept "musical messages." The Magistrates' Clerk stated that if there was music there must be a licence, whereupon the applicant replied that he could not say that wireless was music. It was noise.

Ultimately, the Magistrates advised applicant to wait and see what happened when he had his set ready, when he could renew the application.

Railway Companies' Power Supplies.

The inquiry by the Electricity Commissioners (Sir John Snell and Sir Harry Haward) into the proposals of (1) the S.E. & C. Railways and the Managing Committee of the two companies, and (2) the West Kent Electric Co. in regard to the erection and equipment of electric power stations and the provision of electrical energy for working certain of the S.E. and C. lines, was adjourned from the 1st inst. until Wednesday.

Advantages of Angerstein's Wharf Site.

Mr. C. P. Sparks said he had examined the Angerstein's Wharf scheme. Without extensions of the present wharf into the Thames, seaborne coal could be unloaded there from steamers carrying 1 500 to 2 000 tons, and an alternative source of fuel was available by means of the existing railway connection. By extending the jetty 50 ft. an extra 7 ft. of water would be obtained, and large steamers could be anchored alongside. The contour of the foreshore was favourable for drawing condensing water from the river. The proposal was to supply, in the first stage, 43 000 kW to Lewisham, to Redhill (18½ miles from Lewisham) 5 400 kW, to Tonbridge (24 miles from Lewisham) 3 700 kW, and to Rochester Bridge (25 miles from Angerstein Wharf) 4 600 kW, or a total demand, approximately, of 57 000 kW. Stage 1A comprised the electrification of 94 route miles, a demand of 29 000 kW, annual units required 90 000 000, and operating load factor 25 per cent.; stage 1B comprised 241 route miles, 57 000 kW, 222 000 000 units, and load factor 44½. In stage 2 it was estimated that a similar quantity would be supplied to a future member of the Southern group, raising the kilowatts to 114 000, annual units to 444 000 000 and load factor to 44·4. At stage 1A there would be four turbo-generators of 15 000 kW rating each (two being reserve), and boilers to steam 30 000 kW continuously, with reserve for maintenance purposes. At stage 1B there would be six turbo-generators (2 being reserve), and boilers to steam 60 000 kW continuously. The station might eventually be equipped with 10 generators of 15 000 kW each, of which two would be reserve, and boiler power to steam 120 000 kW continuously, plus reserve. Main distribution would be 25 ~, 33 000 V, three phase. The estimated cost of power was 0·475d. per unit for the 90 million units, 0·345d. for the 222 million, and 0·305d. for the 444 million. The estimates were based on coal at 15s. per ton, and with calorific value 11 000 B.Th.U. per lb., and the estimate of coal per unit was 1·82 lb. Taking the load curve of the power supply, the load factor was estimated at 35 per cent., as there would be considerable time when the plant would not be fully utilised.

Equipment of Station.

Cross-examined by Mr. Tyldesley Jones, witness said the South Western Railway had a 40 per cent. load factor on their suburban railway. They had 25 000 kW, and he thought they had a reasonable amount of spare plant. He was speaking of a load factor taken over half an hour. He had taken the load factor under the present scheme as 35 per cent. on average demand for half an hour with a maximum demand of 29 000 kW and an output of 90 million units per annum. In the first stage there would be 50 per cent. spare of generators only—two generators. He agreed that the larger the generators were the greater would be the saving in capital cost and in operation. The value of the site at Angerstein's Wharf had not been debited to cost of generation. As the company had other land to which the engineering materials now on the site could be removed there would be no cost. His figures for turbo-generators and step-up transformers were based on £4 10s. per kW, to-day's price. It was proposed to have ten boilers (7 working and 3 reserve), each with a capacity of 50 000 lb. of steam per hour. He had in view a pressure of 300 lb. to 350 lb. per sq. in. In stage 1 the whole of the energy would be transmitted to Lewisham. The cables would be 33 000 V, 0·25 sq. in. and three core. Each of the cables would cost £4 650 per mile, together with the control pilots and telephone cables. This cost was based on present day quotations. In stage 1B there would be transmission to Redhill, Rochester Bridge and Tonbridge. The cost might then be different. The centre of gravity of the load would not be altered to any large extent. Probably all the feeders to Redhill and Tonbridge would pass through Lewisham. At the end of stage 1B, Lewisham would require 43 300 kW, Redhill 5 400 kW, Tonbridge 3 700 kW, and Rochester 4 600 kW. Regarding size only, he did not know of any station of that size which had 17 per cent. efficiency, but he did not know of any station similarly equipped. He had allowed 1 per cent. for maintenance, and 7 per cent. allowed for interest and depreciation.

Mr. Herbert Jones, electrical engineer to the L. and S.W. Railway Company, said his company's power station at Wimbledon had been working seven years, had an output of 45 million units a year. It was desirable that the S.E. and C. Railways should adopt 25 ~. It was an advantage to use rotary converters.

System to be Adopted.

Mr. Alfred Raworth, electrical engineer to the S.E. and C. Railway Companies and the Managing Committee, said his companies had had negotiations with the West Kent Company and the London Electric Supply Corporation, and had been unable to get any definite offers from them with regard to a supply of energy. He prepared the scheme of electrification now under consideration. He advocated the use of 25 ~, because 50 ~ rotary converters were not reliable, and motor generators would give lower efficiency.

Cross-examined by the Hon. Evan Charteris (for the West Kent Company), witness said the electrification had not been debited with anything for the site to be occupied by the station. Uniformity of system of collection was more important than periodicity, but they should try to get uniformity in both. A frequency of 50 was better than 25 for purposes other than traction. The systems of collection on the South Western and on the Brighton lines were different, and it was proposed to adopt a third on the S.E. and C. system. The report of the Committee on Electrification of Railways permitted such a system when it could be shown to be financially justified.

Replying to Mr. Kennedy (for London Electricity Joint Committee): The transmission to Lewisham would probably be at 33 000 V. The highest total figure estimated for cost of energy at Angerstein's Wharf was 0·75d., or 0·9d. at Lewisham. He could not say whether there would be any advantage in generating at Angerstein's Wharf compared with Deptford. He would not hesitate to recommend a railway company to take a supply from an outside source if there were any advantage in taking it, and he did not think a railway company must necessarily retain sole control of its generating station.

Uniformity of System Desirable.

Replying to Sir John Snell, witness said he had had conversations with Sir Philip Dawson some considerable time ago in regard to supply of energy to the S.E. and C. system. By or before August of next year the Brighton, the S.E. and C., and the South Western Railways would become one system. It would be a great advantage if the supplies for the railways were obtained from a common source. It should bring about a reduction in cost. Combining railway and other loads should have the same effect. They carried the negotiations as far as they could, but got no definite offer. His original recommendation was to obtain, if possible, a supply from outside if satisfactory conditions could be obtained.

Mr. Sydney Hitchcock (rating surveyor to the S.E. and C.R. Companies and the Managing Committee) said on the basis of a station with 60 000 kW of generating plant he estimated the ratable value at £16 000, at 15s. in the £, or £12 000 a year for rates. Those figures were increased by 50 per cent. for 90 000 kW. On a 150 000 kW station the ratable value would be £40 000 at 15s. in the £, or £30 000 per year. He had checked these figures by the actual figures for the S.W. Company's Wimbledon generating station. At Belvedere (in Erith) rates for the year to March 31 last were 29s., and there was also a sewerage rate (7d. last year and 3d. this year). This year the poundage was 27s., but in Greenwich the rate this year was 17s. 2d.

On the resumption of the proceedings, Mr. Tyldesley Jones opened the case for the West Kent Electric Company, and the inquiry was continued yesterday (Thursday).

Legal Intelligence.

Trading With Infants.

At the Shoreditch County Court, last week, Thos. Cook and Co., Ltd., sued J. Rurka, trading as the British Commercial Trading Co., of 61, Chancery Lane, W.C. It appeared that defendant ordered goods to the amount of £21 12s. 4d., before December 7, 1921, and these were admittedly delivered on dates from December 9 to 21. When payment was demanded, defendant said he was only 21 years of age on December 7, so that he was not of age when the contract was made, and was not liable.

On Friday, Judge Cluer said he had allowed the matter to stand over to see if he could make defendant act honestly. It was clear defendant was an infant when he made the contract, and the Statute clearly said that all contracts made by an infant were void. There would have to be judgment for defendant and costs.

Mr. Robinson (for plaintiffs): The matter now gets into the police court, as we have information as to what he has done with the goods.

Judge Cluer: I am very pleased indeed to hear it, and it will be good news to a number of infants who are trading in this district.

Altering an Electric Meter.

Last week the Colchester Bench fined William Godfrey £5 for altering the index of an electricity meter at the Sea Horse Hotel, and the wife of the proprietor was also fined £5 for counselling and procuring the commission of the offence.

Transferring a Telephone.

At the Mayor's and City of London Court last week the Postmaster-General sued the Seat Indicator and Advertising Syndicate, of Chiswick, for £5 13s. 4d. for arrears of telephone rental.

For the defence, Mr. Wm. Hammerton said he had carried on the business of the Seat Indicator Syndicate. A man named Moody had taken over his business and agreed to pay the Postmaster-General's charges. He, therefore, brought Moody in as a third party.

Judge Jackson pointed out that that did not exempt the defendant from liability, as the Postmaster-General had not made the agreement with Moody. Judgment must be given for plaintiff against the Seat Indicator, and Hammerton would have an indemnity over against Moody, with costs.

Busy Europe: Politics and Business.

By Sir ERNEST BENN.

The very natural prominence which has been given to political questions, and the frequency with which international conferences are held, and international crises developed and settled, are natural outcomes of the War and the Treaty of Peace, but these things are giving to us and the world in general a dangerously false impression of fundamental conditions in Europe, and are doing much to retard that resumption of normal trade and commerce upon which all so much rely. A close study of the full report of the Genoa Conference leaves one with the impression that Europe is a pitiful mass of dejected peoples all vying with one another to explain how unbearable are their burdens, and how bad is their plight. There is, of course, a certain amount of truth in all this, but it is of the greatest importance that most of these questions should be got into better perspective.

For instance, there is often a very marked difference between the position of a nation and the position of the individuals who compose that nation. A national balance sheet may be a very discouraging document, while the balance sheets of the individuals who make up the same nation may be in the most flourishing condition. If, therefore, a nation is bankrupt, it does not necessarily mean that the nationals are undesirable customers, or that they may not themselves be wealthy persons, capable of transacting very desirable business.

Undue Prominence of Political Problems.

Many of the questions which loom so large in the newspapers and occupy so much time in public discussion, and sound so important when discussed in broad principle, are of no more interest or moment to the persons inhabiting the countries concerned than is the question of Proportional Representation to the average English citizen. Yet because these political matters are so much before the public, they are allowed to cloud our vision, and give an impression in commercial circles, in England certainly, that Europe is not in a fit position to trade, and that the markets of Europe are for the time being not worth consideration. There are, of course, many people who know better, but our trading figures disclose all too clearly how widely these false impressions are held.

To take a few examples: the city of Vienna brings to the mind of the average Englishman, famine, rickety children, absence of food, poverty, and general wretchedness and starvation. That is the effect upon the mentality of the public of all the efforts which have been made to alleviate the distress which did undoubtedly exist in certain parts of Vienna a couple of years ago. Vienna to-day is by no means happy, but no more is London or Manchester. And Vienna is full of ordinary, active, business mortals, getting along with the ordinary work of life in a more or less ordinary way, and desirous and indeed anxious to develop commercial relations with the rest of the world. The same sort of misunderstanding, arising from the undue prominence of political problems, is seen in connection with Germany. Or, speak of Hungary, and the English mind turns at once to Bela Kun, to whites and reds, to revolutions and counter-revolutions, to massacres and pogroms, and other political incidents, traces of which it is very difficult for the ordinary commercial visitor to find when he travels in this delightful land. There is no doubt at all that things are not what they were in Hungary, or what they will be again, but there is equally no doubt that business is waiting to be done in Hungary and that conditions are quite good enough for the business man who will take the trouble to study them.

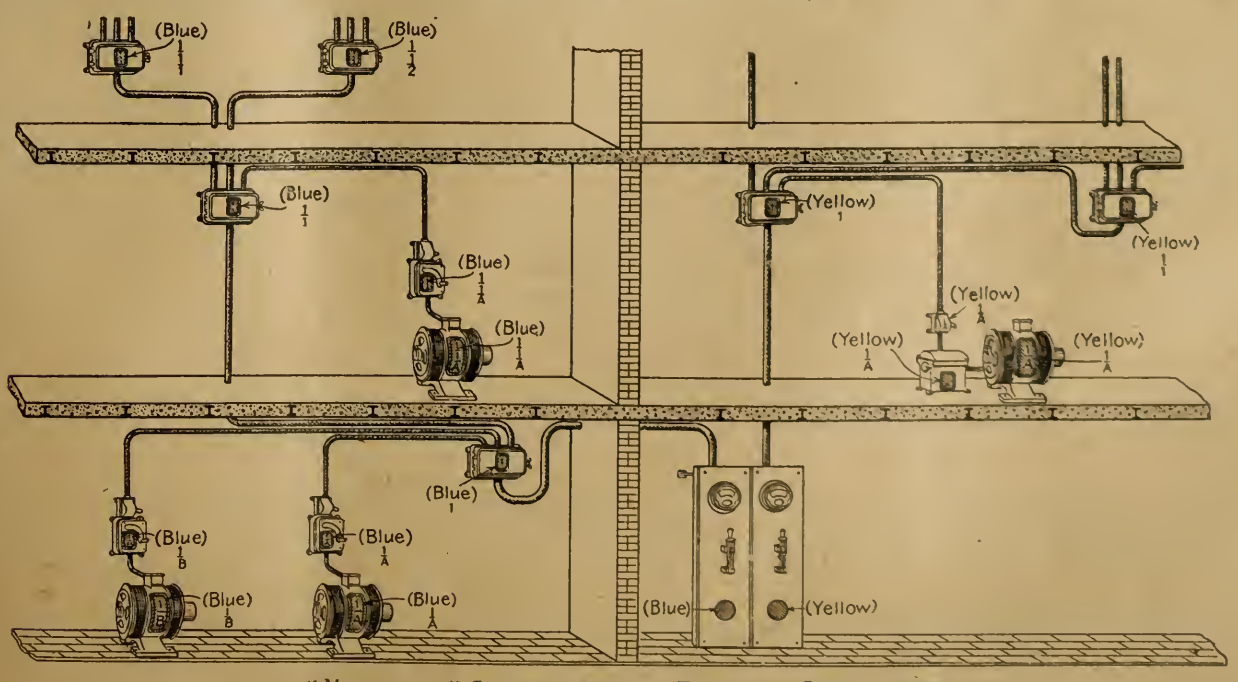
Russia is supposed to be closed to normal business and for practical purposes that is undoubtedly so, but nevertheless, it is significant to notice that the Russian rouble is quoted on the Berlin money market. On May 22, seven and a half million roubles could be purchased in Berlin for a sovereign. It is surely not to be presumed that people buy seven and a half million roubles for the fun of looking at them, and it is hard to imagine any use to which these roubles can be put except for the purchase of Russian goods; further, it is difficult to see how these same roubles got into Berlin except in return for German goods delivered in Russia.

Trading Difficulties Exaggerated.

There are other ways in which our knowledge of the Continent of Europe is by no means as complete and accurate as it should be. In political discussions a very great deal is made of the inconveniences which arise from passport arrangements. Within the last few months I have crossed and re-crossed all the frontiers of Central Europe, and I can state without the least hesitation that there is no frontier in the world that I know, except New York, which has half the terrors, half the inconveniences, or half the indignities that are put upon one in endeavouring to enter an English port. The currency difficulties are quoted far too commonly as an excuse for the absence of business. A fluctuating currency is a great inconvenience. It would be absurd to belittle the seriousness of the position of some of the European countries in this matter, but a fluctuating currency is, nevertheless, not a bar to business, if the business man is willing to take a little extra trouble. Many firms are adopting the very simple expedient of doing business both ways; one well-known manufacturer is selling his goods freely in a country with a very uncertain currency, he having taken the precaution to provide himself with two or three buying agencies, thus enabling him to buy and sell and balance his books, and be completely independent of any fluctuation in the rate of exchange. The politics of Europe are important, but it is equally important that we should not allow impressions gained in the political field to warp our views on commercial matters, or to mislead us into a totally erroneous impression of commercial possibilities.

"Manifoldia" System of Supervision.

In referring to the Industrial and Efficiency Exhibition at Birmingham, in our last issue, brief mention was made of the MANIFOLDIA (REGD.) SYSTEM for ensuring the perfected supervision and record keeping of electrical installations. The system, which was exhibited on the stand of Manifoldia, Ltd., of West Bromwich, has been designed by Mr. A. H. Human, and its interest and value lie in the labelling provided by which the distinguishing number of each individual item of plant in an electrical installation gives also its geographical position in relation to the rest of the installation. Thus is ensured the systematic and periodical examination, cleaning and routine overhaul of the installation. All repairs and alterations of items of plant are recorded and brought automatically to the notice of the manager, and so the system affords, it is claimed, an insurance against delay in restarting a plant after a shut down. Another advantage secured is that the system allows the manager or engineer to keep before him essential data which will enable him to appreciate immediately how much his plant is costing him in repairs, maintenance and energy, and the extent to which these items of cost vary from time to time.



"MANIFOLDIA" SYSTEM APPLIED TO ELECTRICAL INSTALLATIONS.

D

Electricity Supply.

The Electricity Commissioners will hold their second local inquiry at Birmingham on the 29th inst. into the scheme for the reorganisation of electricity supply in the South West Midlands Electricity District and in order to determine finally the area of the district.

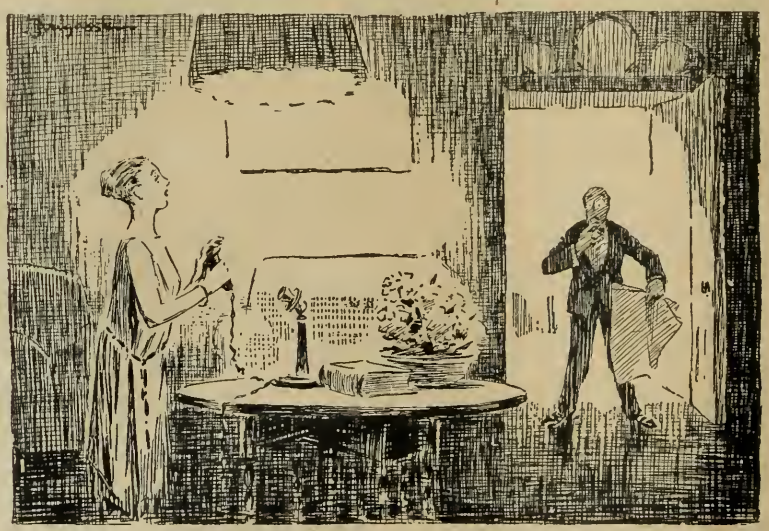
One of the Cardiff papers remarks that, if the Barry Council decides to go in for an electric supply scheme, it should see that it is in a position to supply electric fittings on a hire purchase system, as the absence of this power on the part of Cardiff Corporation has retarded the extension of electricity supply in that city.

The Minister of Transport proposes to confirm the Folkestone Electricity (Extension) Special Order, 1922, authorising the Folkestone Electricity Supply Company, Ltd., to supply electricity in Cheriton Urban and Elham Rural Districts. Any objections must be sent by June 26 to the Secretary, the Ministry of Transport.

Lancaster Electricity Committee have passed a resolution to the effect that no undertaking of an authorised undertaker should be shut down unless a supply of electricity could be obtained from some other source at a lower cost to the undertaking than the authorised undertaker could generate it, and every such authorised undertaking should be free to develop so long as it is able to generate at a cost not greater than it can obtain a supply from some other source.

The Electricity Commissioners will hold an inquiry on June 13 into the Order of Liverpool Corporation to extend their area of supply to Bootle, Waterloo, Seaforth, Litherland, and Great Crosby. The inquiry is necessary solely because objections to the Bootle transfer have been lodged by a section of the consumers and ratepayers of that borough. Instead of the £7 500 subsidy, the objectors ask for £12 500, or in the alternative one-ninth of any profits above £67 500 on which the £7 500 to be paid by Liverpool to Bootle annually is based. It is also contended that the compensation for loss of office should not be limited to the Bootle borough electrical engineer, but given to the rest of the works staff.

A Little Learning is a Dangerous Thing.



"I say, Harold, those ghastly people, the Dudd-Robinsons, have asked us to one of their filthy dinners on Tuesday. Tell me what excuse to make while I keep my hand over the telephone."

Reproduced by kind permission of the proprietors of "Punch."

New Schemes and Mains Extensions.

Kendal Town Council has decided to expend £11 655 on new plant and cables in connection with the electricity undertaking.

Folkestone Electric Supply Co. have been granted an Order to supply electricity to Cheriton, Saltwood, Newington and Hawkinge.

Newcastleton electric supply scheme has now been completed. The power station is said to be the smallest in the British Isles. The installation has cost £600.

Croydon Town Council has applied for a loan of £14 700 for steam raising plant at the electricity works. The original estimate of the cost of the plant was £23 000.

Denbigh Town Council have appointed the firm of Sloan and Lloyd Barnes, consulting electrical engineers of Liverpool, to prepare a scheme for supplying electricity to the Vale of Clwyd area.

It has been decided to light the streets of Welwyn Garden City by electricity. A contract is to be entered into with the local supply company and steps are being taken to obtain the necessary loan from the Electricity Commissioners to cover the cost of installation.

Elgin Town Council have agreed to the terms put forward by Mr. Williams, manager of Edmundson's Electricity Corporation, with regard to supplying the burgh with electricity. A committee has been appointed to carry out the various details, and work is to be started as early as possible.

The new sub-station at Stockton Heath which was opened last month receives its supply from the Warrington Power Station by means of duplicate e.h.t. cables which run underneath the Manchester Ship Canal. The generation and transmission pressure is 6 600 V. 3-phase, 50 periods, but at the sub-station the pressure is reduced by transformers to 440 V. for power and 250 V. single phase for lighting, domestic power and heating purposes. The h.t. switchgear consists of ironclad truck panels made up in single units, and designed to facilitate extension. A switch panel is provided for coupling up to the Latchford sub-station now in course of erection. From this sub-station the transmission cable will be continued to meet the cable running down Knutsford Road, which crosses the Manchester Ship Canal by the railway bridge near Latchford Locks, and if any accident should occur to the duplicate cables through the canal subways, a supply will be available through the Knutsford Road cable. The cables were laid by the Warrington Electricity Department's staff. The h.t. switchgear was erected and the l.t. switchgear was designed and erected by the Department.

Alteration of Charges.

Eccles Town Council has reduced the advance of 100 per cent. on the standard rates of charges for electricity by 25 per cent. with a discount of 5 per cent. for prompt payment.

The charges for electricity at Stoke Newington have been reduced as follows:—Lighting, 7d. to 6½d. per unit; heating, 2½d. to 2d.; power, 5d. to 4½d. on the first 1 000 units consumed.

Preston Town Council has reduced the charges for electricity for lighting by allowing 10 per cent. discount for payment in three weeks. For power the discount will be increased from 5 to 15 per cent.

Maidenhead Electricity undertaking for the past year showed an increase of 61 306 units over 1920. It has been decided to reduce the flat rate to 9½d. in the borough, and make a reduction of 5 per cent. on other rental meter charges for lighting and power.

The Kent Electric Power Co. has decided to reduce, as from July 1, the price of electricity for lighting and power at Rochester and Chatham to 10d. per unit for the first 400 units per quarter, and to 7½d. above 400 units. Power charges are to be reduced from 4d. to 3½d.

Demand Attachment for Watthour Meter.

For smaller power installations, which cannot use the more expensive graphic demand meter, or where the indicating type of demand meter is satisfactory, a demand attachment for use with a standard type OA polyphase watthour meter is being manufactured by the Westinghouse Electric and Manufacturing Company. The attachment is a watthour meter register, which combines the regulator watthour meter register with the scale and pointers of an indicating demand meter. By replacing the register and cover of a standard polyphase OA watthour meter with this attachment and a special cover, the meter is converted into an indicating block-interval demand meter, which will indicate the maximum kilowatt demand and the integrated kilowatt hours.

The demand attachment has two pointers, one white and the other black. The white pointer advances the maximum demand black pointer to any maximum demand position on the demand scale, where it is held by friction while the white one returns to zero at the end of each time interval. By watching the movement of the white pointer, which shows an integrated and not an instantaneous demand, the duration of the demand interval can be checked as well as the demand at the time of reading the meter. After the gears driving the white pointer have been disengaged from the gear train of the watthour meter, the pointer is returned by gravity to zero. The time at which the gears are disengaged, and therefore the time interval of the attachment, is determined by an induction motor, which, although small, gives several times the torque necessary to release the white pointer. The motor has practically a constant speed over a voltage range varying from 90 to 110 per cent. of the rated voltage. The demand scale, which is 3¼ ins. long, is marked directly in kilowatts demand, but the watthour dials are used with the register constant of 10 or multiples of 10.

Personal and Appointments.

Mr. A. A. Campbell Swinton has joined the board of W. T. Henley's Telegraph Works Co.

Lord Ashfield has been appointed hon. president, and Sir Sam Fay, president, of the Institute of Transport for the year 1922-23.

Mr. John Jackson, of Halberton, near Tiverton, has been appointed electrical engineer at the Royal Devon and Exeter Hospital, Exeter.

Major T. F. Purves, assistant engineer-in-chief to the Post Office, has been appointed engineer-in-chief in succession to Sir William Noble, whose retirement we announced last week.

Mr. Gerald Bellhouse has been appointed Chief Inspector of Factories in succession to Mr. R. E. Graves, whose death we announced in our issue of May 26th. Mr. Bellhouse has been Deputy-Chief Inspector since 1917.

The marriage took place at the Parish Church, Queenborough, Kent, on May 27, of Mr. Roger Hodgson, chief electrical engineer, R.N., of Newcastle-on-Tyne, and Miss May Crowe, youngest daughter of Mr. Crowe, of Eastchurch, Sheppey.

Mr. A. J. Abraham, of Aberdare, has been appointed electrical engineer and tramway manager for Bexley Urban Council at a salary of £500 per annum. Mr. Abraham is at present chief engineer and general manager of electricity and tramways of the Aberdare Urban District Council, a post which he has held for the past twelve years.

Sir William Noble, who, as we announced in our issue last week, has just retired from the position of engineer-in-chief to the Post Office, has accepted a seat on the board of the General Electric Co. We understand that Sir William proposes to devote his attention mainly to the development of the telephone and wireless sections of the Company.

The marriage took place at St. Mary's Church, Leigh Woods, Bristol, on June 1, of Mr. H. F. Trewman, Prof. of Electrical Engineering at the Artillery College, Woolwich, and Miss V. C. B. Morse, only daughter of Mr. and Mrs. R. W. Morse, of "Alpenfels," Leigh Woods, Bristol. The presents included a pair of silver vases from the electrical engineering branch of the Artillery College, Woolwich.

Mr. H. H. Burness has been appointed Lecturer in Civil Engineering at the University College of Swansea. While serving an apprenticeship of five years with Messrs. G. Anderson, he gained First-class Honours at Dundee Technical College, then went to St. Andrew's University, where he graduated in civil engineering. Afterwards he acted as assistant to the construction staff of the Dundee Electricity Department under Mr. H. Richardson. For the last twelve months Mr. Burness has been acting as assistant lecturer in Victoria University, Manchester, under Prof. A. H. Gibson.

Among the King's Birthday Honours we notice the following:— *Peer:* The Right Hon. Sir Archibald Williamson, Bart., M.P., Financial and Parliamentary Secretary to the War Office, 1919-21. Sir Archibald Williamson has taken a noteworthy part in Parliamentary affairs, having acted as chairman of various committees, including those on Telegraph Organisation and on Electric Power Supply. *Baronet:* George Sutton, M.I.E.E., chairman and managing director of W. T. Henley's Telegraph Works Company, a founder and past chairman of the Cable Makers' Association. *Knights:* Edwin Airey, Governing Director of William Airey and Son, engineers and contractors. Ernest Montague Hughman, late partner in Pyne, Hughman and Co., engineers and shipbuilders. Member of Council of Institution of Engineers, India, and Hon. Secretary Indian Council English Institution of Electrical Engineers; William Walker, C.B.E., recently retired from the post of Director of Health and Safety in the Mines Department of the Board of Trade. *Knight Bachelor:* Thomas Ranken Lyle, D.Sc., F.R.S., chairman of the Electricity Commissioners of the State of Victoria.

Business Items, etc.

Messrs. Hill and Provo have started business as electrical engineers, at 36, St. Michael's Street, Oxford.

Mr. W. J. May has been appointed sales manager and secretary of Pope's Electric Lamp Co., Elasta House, 5, Arthur Street, W.C.2.

The office of the British Empire Chamber of Commerce in the U.S.A. is now situated at Cunard Buildings, 25, Broadway, New York.

The North-Eastern District Office of Ferguson, Pailin, Ltd., has been removed to 90, Pilgrim Street, Newcastle-on-Tyne. Telephone No.: Central 5574. Telegraphic address: "Tension" Newcastle-on-Tyne.

On the 6th inst. the Electric Construction Company moved to new offices at Ingersoll House, 9, Kingsway, London, W.C.2. Their telephone numbers are Gerrard 8833 and 4606, and the telegraphic address "Concordance, Estrand, London."

The Jeary Electrical Co. have taken larger premises in Glasgoe, and their address in future will be 95, Waterloo Street. (Telephone: Central 5239.) Mr. John Grogan, the Scottish manager, will be pleased to give his personal attention to all inquiries.

Mr. A. T. West and Mr. J. S. Williams have resigned their positions with Pope's Electric Lamp Co., and have joined the "Z" Electric Lamp and Supplies Co. Mr. West will represent the company in the Southern and Eastern Counties, and Mr. Williams has been appointed Northern manager at the company's new branch at 10, Hockenhall Alley, Dale Street, Liverpool.

Realising the importance of extensive advertising, the Benjamin Electric, Ltd., is launching an intensive publicity campaign. Broadly, the scheme consists of an attractive series of full-page and half-page advertisements in the motor press. The advertisements are designed to create the demand on the retailer, and in addition, the company are sending to the whole of the motor trade throughout the country a series of four special folders at regular intervals containing actual reproductions of the advertisements to appear in the ensuing weeks so as to enable the recipient to visualize what they are doing in order to create the demand on him. They are also preparing a series of small leaflets, attractively printed, describing the various accessories, for distribution to consumers, and are prepared to supply quantities of these overprinted with the retailer's name and address.

A new and important company for the production of high-class wireless instruments of entirely new design has recently been formed under the name of Radio Instruments, Ltd. Mr. J. Joseph, who has recently resigned his position as general manager for Mr. H. W. Sullivan, and who has been associated with the design and manufacture of wireless instruments for the past 23 years, has been appointed managing director, as from June 1. In addition, the company has secured as director of research and chief designer the services of Mr. W. A. Appleton, late Admiralty technical research officer at H.M. Signal School, Portsmouth. The works, offices, and showrooms are situated at 12A, Hyde Street, New Oxford Street, W.C.1, within a few yards of the British Museum Station, and their central position renders them readily accessible from all parts of London. A special department will deal with laboratory standards and radio measuring instruments, and the company will be pleased to receive enquiries and advise on any special problems in connection with high frequency and radio work.

Electric Traction.

The Mile End Road extension of the South Shields Corporation Tramways and the new light railway to Cleadon Park were opened to the public last week.

London County Council have sanctioned a loan of £6 077 to Islington Borough Council for the purchase of four 2½ ton electric lorries and one 4 ton petrol vehicle.

West Hartlepool Tramways Committee recommend the Town Council to introduce trackless trolley trams on the Foggy Furze route. It is estimated that the running expenses of these trams will be about a third cheaper than that of the present system, and that the initial expenditure will be about one-half.

After full consideration Southport Tramways Committee has come to the conclusion that owing to the high cost of running omnibuses there are no districts in Southport where it would pay to run them as feeders to the trams. They are also unanimous in the opinion that it would not be advisable to substitute buses for trams.

The Ministry of Transport having refused the application of Burnley Tramways Committee for a suspension of payment to the sinking fund for tramway constructional works for a period of five years, in order to utilise the money for relaying certain tracks, the committee have applied for sanction to borrow £46 950 to carry out the work.

At Edinburgh Council meeting last week a motion by Mr. Whitson disapproving the Council's decision of May 4 to electrify the Hanover Street–Mound tramway route was carried by a large majority. It was stated that it would cost £80 000 to electrify this route, and that by electrifying 300 yards of the Chambers Street track people travelling by car from the North Side to the Infirmary might be taken by Broughton Street, Leith Street, the Bridges, and Chambers Street, and so the £80 000 proposed to be spent on the Hanover Street-Mound route would be saved.

The question of the electrification of some of the steam railroads in Quebec and Ontario was recently discussed in the Dominion Parliament. A member asserted that the railway in the St. Maurice Valley could be worked very much better and cheaper by electricity than by steam, and as the Canadian Pacific Co. proposed to convert the line from Montreal to Quebec the urban lines around Montreal should have been electrified. In reply, the Minister of Railways said his Department was keenly alive to the situation, and as soon as financial conditions warranted a heavy expenditure the matter would be dealt with.

Foreign Notes.

The German Syndicate of Manufacturers of High Tension Insulators have decided to increase prices as from June 1 by about 40 per cent.

Lucerne and Goldau electric railway, on the Saint Gothard line, was opened last week. The first train ran from Goldau to Lucerne in 32 minutes, with three stops.

Mr. C. G. Schluderberg, of the Westinghouse Electric and Manufacturing Co., has been elected president of the American Electro-Chemical Society for the ensuing year.

Progress is being made with the electrification of the first section of the Central Brazil Railway (about 53 miles), and orders have been let in the United States for the supply of 22 electric locomotives and 150 motor coaches.

Two large electric locomotives have been built by the Ganz Danubian Works of Budapest, and will shortly be tested on a strip of line which has been electrified with a view to the ultimate electrification of the Hungarian State Railways.

Fire Risk Rules for Radio Equipment have been drafted and are under consideration by a committee of the National Board of Fire Underwriters. In the meantime copies of a tentative code have been circulated by the Department of Commerce.

Los Angeles Municipal Council recently acquired for $12 044 370 the distributing networks of the Southern California Edison Company which are within the municipal boundaries. The Council has undertaken to take all bulk supply needed from the company and not to compete with the company outside the municipal area.

An electric light company was recently organised by the merchants in Tehtsing, Chekiang. The Ling Hu Tung Li Electric Light Co., of Huchow, Chekiang, has been granted a license by the Ministry of Agriculture and Commerce. The Pao Sing Electric Co., in Hupeh, has been registered by the Ministry of Agriculture and Commerce.

For the year ended March 31 last the sales of the Westinghouse Electric and Manufacturing Co. amounted to nearly $100 000 000, a higher figure than in any previous year, except in 1919–21. The net profit was $6 260 180, and after taking into account miscellaneous receipts and paying bond interest, etc., the amount available for dividends was $5 837 389. The orders booked since January were higher than in 1921 and there has also been a keen demand for radio-telephone receiving apparatus.

The possibility of electrifying two or more divisions of the National Railways of Mexico is being investigated. As oil fuel must be hauled from Tampico, it is thought that electric traction would be more economical than steam upon the mountain divisions, especially as there is an abundance of hydro-electric power available. The Guanajuato Electric Light and Power and the Northern Power Companies are in a position to supply electricity if required, but it is thought an independent plant or plants may be erected.

Important changes have recently taken place in the directorate of the General Electric Co., of America. Mr. C. A. Coffin has retired from the chairmanship and is succeeded by Mr. O. D. Young, and Mr. Gerard Swope becomes president in place of Mr. E. W. Rice, jun., who will devote his whole attention to the scientific and engineering phases of the company's business. Other changes and promotions have also taken place. Mr. Coffin remains a director, and the office of hon. chairman has been created for Mr. Rice.

In order to stimulate interest in hydro-electric development in Brazil it has been decided to hold a hydro-electric congress in connection with the forthcoming Centennial Exhibition at Rio de Janeiro. The potential wealth of the country in undeveloped water power has not yet been fully investigated, but it is known that its resources are large and the approximate capacity of several falls has been calculated. It is expected that the Congress will lead to more organised efforts to utilise water power for industrial purposes and for traction.

Mr. J. E. Aldred, a New York banker, is reported to have acquired a controlling interest in certain Italian Hydro-electric Companies which supply electricity in Milan, Venice and Turin. Between $25 000 000 and $50 000 000 will ultimately be invested in these enterprises, and Mr. Aldred's engineers are at present in Italy preparing reports on the undertakings. The financial arrangements will, it is stated, be worked out in New York and London. Mr. Aldred is president of the Shawinigan Water and Power Co., and chairman of the Pennsylvania Water and Power Co. and of the Consolidated Gas, Electric Light and Power Co. of Baltimore.

The Paris Orleans Railway has recently placed an important order for electric equipment, including 80 freight locomotives and 80 heavy high-speed passenger motor cars for the section of the main line between Paris and Vierzon, a distance of about 125 miles. This section is being electrified on the direct current, 1 500 V system, and most of the equipment will be supplied by French electrical manufacturers, including the Compagnie Française Thomson-Houston, but it is expected that some American material will be used. The order for the electric locomotives, which will weigh 250 000 lb. each, and be capable of running at speeds of 80 and 85 miles an hour, has not yet been given out, but it is expected that the company will do so at an early date, and also let additional tenders for equipment, as about 2 000 miles of line are to be electrified.

Exhibition Notes.

The British Industries Fair (Birmingham) is to be held from February 19 to March 2 next year.

The sum of £60 000 has now been guaranteed by Manchester for the British Empire Exhibition, which will be held next year. This is the largest amount guaranteed by any city outside London.

At a meeting of the guarantors in connection with the proposed Welsh National Exhibition to be held in Cardiff, it was decided, in view of the industrial conditions obtaining at present, to postpone further discussion on the matter until May, 1923, by when, it is hoped, the time will be more favourable.

It has been decided to hold the Shipping, Engineering, and Machinery Exhibition at Olympia in September next year. Dr. H. S. Hele-Shaw, president of the Institution of Mechanical Engineers, has been elected chairman of the Hon. Committee of experts, with Captain H. Riall Sankey, vice-chairman.

In view of recent announcements of a projected voyage round the world by the steamship *Orontes*, renamed *British Trade*, the directors of British Trade Ship, Ltd., announce that this ship has no connection whatever with British Trade Ship, Ltd., whose proposal is to build a special ship for the purpose of an exhibition and send her round the world in 1924.

The International Technical Exhibition of Engineering will be held at Liége from June 11 to July 14, under the organisation of the Association des Ingenieurs de l'Ecole de Liége. At the last exhibition, organised by the Association in 1905, there were nearly 1 200 exhibitors, representing more than 30 nations. The exhibits will include machines and machinery equipment, instruments, models, books, plans, diagrams, and all documents relating to engineering.

An International Metal Industries Exhibition is to be held at Ghent from June to October next year, under the patronage of H.M. the King of the Belgians and with the co-operation of the Belgian Government, and the Province and City of Ghent. It is intended, the Department of Overseas Trade states, to form a British section, the official representative for which in the United Kingdom is Mons. C. J. A. Lobo, Shirley House, 10, Throgmorton Avenue, London, E.C.2. The exhibits, covering every branch of the metallurgical industry, will be divided into 13 main groups and 46 classes, all confined to articles with a metallic construction of not less than 50 per cent. German exhibits, however, will not be admitted. The main groups include:—General mechanical apparatus; metallurgy and mines; machine tools; electricity; decoration and hygiene of the home (five classes—lighting, heating, ventilation, sanitation, ironmongery, etc.); transport.

Wireless Notes.

Remarkable records were made in cabling the result of the Derby last week. The Eastern Telegraph Company received the names of the three winning horses at 3.24½ p.m. at their offices in Moorgate, London, and telegrams recording this result were delivered in Bombay at the local equivalent of 3.26 p.m. (London time); in Sydney at 3.27 p.m., in Durban at 3.26 p.m., and in Calcutta at 3.30 p.m. Owing to the immense interest created by the race all over the world, special arrangements were made to clear the lines. The Imperial Cable also achieved a remarkable record. The result of the race was telephoned to the Central Telegraph Office, and was immediately transferred to the Imperial Cable. The message arrived in Sydney at 3.30 p.m. English summer time, which is equivalent to 12.30 a.m. Australian time, or six minutes after the time of despatch from London. The previous record in the time of transmission by the Imperial Cable between the Central Telegraph Office and Australia was eleven minutes, on the occasion of the 1921 Derby.

The wireless message sent out at the instance of the Chief Constables' Association on Friday last from Marconi House, London, respecting the apprehension of an imaginary criminal, was clearly heard by a representative of The Electrician who was "listening-in" at the workshop of Mr. G. Castagnoli, at Braintree, Essex. The message was also picked up by a "detective" provided with a portable receiving set for the purpose of the experiment between Chelmsford and Braintree. The wording of the despatch was as follows:—"Wanted at Chesterfield on a charge of obtaining food and money value 5s. by false pretences from William Stiggles, with intent to defraud, on May 21, 1922, Frank Beecroft, alias Bennett and Merchant; ship's cook; no fixed abode; age 32, height 5 ft. 4½ in.; brown hair, inclined to be curly, hazel eyes, mole under right eye. Warrant issued. Information to Chief Constable, Chesterfield." Three of the most important words, namely, the surname and alias of the fugitive, were not rendered quite so clearly as they might have been, and it would appear to be advisable to repeat each name letter-by-letter.

A military telephone between Tsingkiang and Chunghing has been installed by the Kiangsu military authority with the approval of the Ministry of Communication.

The Rutenberg Concession.

In the House of Commons on the 31st ult., Mr. A. T. DAVIES asked the Secretary of State for the Colonies by what authority the High Commissioner for Palestine granted a concession for important public works to Mr. Rutenberg; what efforts or inquiries were made by the High Commissioner to discover British engineers who could command the capital necessary to carry through the work in contemplation; what were the names of the capitalists in the United States who were finding the necessary capital for Mr. Rutenberg; and whether the High Commissioner was empowered to grant concessions to foreigners without consultation with his Majesty's Government.

In reply to the first and second parts of the question, Mr. CHURCHILL referred his questioner to the statement made in reply to a question by the member for Twickenham on November 7 last. Mr. Rutenberg had not yet received the concession referred to, but an agreement was concluded with him in September, 1921, under which, provided he succeeded in forming a limited liability company with adequate capital within two years from that date, the concession would be granted to the company on application. The agreement was concluded under the authority of H.M. Government. No such company had yet been formed, and he was consequently unable to give any information as to the source from which the capital was to be provided.

With regard to the last part of the question, the High Commissioner was not empowered under present conditions to grant concessions of any kind without the prior approval of H.M. Government.

German Scientific Instruments.

At last week's sitting of the Committee appointed under the Safeguarding of Industries Act to inquire into the complaint by British manufacturers of optical and other scientific instruments of alleged unfair German competition, the case for the importers of German goods was heard.

Mr. Inskip, K.C., M.P., on behalf of seven agency firms, said that every effort was made to keep German trade in the hands of authorised agents who were not permitted to sell articles below certain prices. Though illegitimate trade was being done from Germany, the genuine agents were not putting goods on the market in competition with British goods at unfair prices. Scientific study was an international affair, and people were prepared to purchase microscopes regardless of expense. He urged that it was not German, but American and French competition that affected British manufacturers.

PROF. W. A. BONE said that scientific workers were impeded and retarded by the duty on foreign instruments. Their work demanded the very finest apparatus that could be procured, and in many cases such could only be purchased from abroad. An increased price of instruments would be a hardship to students. Already drawing and experimental equipment had increased in price in some cases by several hundred per cent. The consensus of opinion was decidedly that microscopic lenses made abroad were slightly better than those made at home.

Agents for German instruments said that their trade had greatly fallen off since the imposition of the duty of 33⅓ per cent.

The Committee adjourned until June 19.

Institution Notes.

The annual conversazione of the INSTITUTION OF CIVIL ENGINEERS will be held at the Institution Building in Great George Street on Tuesday, June 27.

The 27th ANNUAL CONVENTION of the INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION will be held at Wolverhampton from Tuesday, June 20, to Friday, June 23. In our Arrangements for the Week we give the complete programme of the proceedings.

The BRITISH NON-FERROUS METALS RESEARCH ASSOCIATION has just issued, in its quarterly Bulletin, a Union List of Periodicals of interest for reference on industrial metallurgy. The service provided by fourteen libraries in London, Birmingham and Manchester is clearly indicated so far as concerns the 118 periodicals which have been selected, and the next edition will include additional libraries and periodicals which experience with the present list suggests as desirable.

The POWELL DUFFRYN COAL COMPANY, which is engaged in large colliery developments in South Wales, have made great progress towards the complete electrification of their pits. The main power station is at Bargoed, and an extension to this has just been completed by Heenan and Froude. The capacity of the turbo generators is 18 000 kW, and another set is to be installed of 12 000 kW capacity. In the Aberdare Valley there is another main power station having a capacity of nearly 30 000 kW. From these main stations the power is transmitted to the several pits and sinkings by means of overhead cables supported on steel latticed transmission poles.

Miscellaneous.

On the 31st ult. the ROYAL ASSENT was read to the following new Acts of Parliament: Ayr Burgh (Tramways), etc., Confirmation Act, Metropolitan Railway Act and Yorkshire Electric Power Act.

While placing a belt round some shafting at the electrical porcelain works of Gaskell & Grocott, Longport, last Friday, JOHN COOPER was caught by the belt, and his left arm was torn off from the shoulder and his chest badly crushed. He is reported to be in a critical condition.

An order was made on May 27 for the RESTORATION OF PATENT No. 1453, of 1915, granted to George Saint for "Mercury globule electrical contact maker for releasing mine winding signal indicators, actuating indicators of the stopping, starting and reductions of speed of machinery and the like."

An application has been made for an EXTENSION OF THE PERIODS OF PATENTS Nos. 21290 and 23271 of 1906 granted to Joseph Johnson and John Tetley. Notices of opposition must be lodged at Mr. Justice Sargant's chambers, 317, Royal Courts of Justice, Strand, London, W.C., seven days before July 7, when an application will be made to the Court concerning the matter.

The NATIONAL ASSOCIATION OF SUPERVISING ELECTRICIANS will hold a smoking concert at the St. Bride's Institute, Ludgate Circus, London, E.C., on Tuesday, June 13th, at 7.30 p.m. At this gathering, which will bring the 1921-2 Session to a close, Major T. Vincent Smith will resign his office on the ground of ill-health and will hand over his duties to his successor, Mr. W. E. Highfield, who has accepted the office of president.

At the annual conference of the ASSOCIATION OF TEACHERS IN TECHNICAL INSTITUTIONS, held in London last week, a resolution urging that the time had arrived when the position of technical education should be reviewed, and asking for the appointment of a committee of inquiry to investigate the whole field of technical education, was moved by PROFESSOR G. KNOX, of South Wales and Monmouth School of Mines. The motion was carried, also another resolution "viewing with alarm the reduction in the number and value of scholarships available for higher education."

The Board of Trade state that they have received a complaint by the British Electrical and Allied Manufacturers' Association that vulcanised fibre manufactured in the U.S.A. is being sold in the United Kingdom at prices below the cost of production as defined by the Safeguarding of Industries Act, 1921, and that in consequence employment in the vulcanized fibre industry in the United Kingdom was likely to be seriously affected. They have therefore appointed a committee to inquire into the case. The first sitting for the taking of evidence will be at 11 a.m. on Tuesday, June 20, at 5, Old Palace Yard, Westminster, London, S.W.1.

An example of BROAD TENDERING BY BRITISH CONTRACTORS who compete for orders in India is given in the "Times Trade Supplement." The Corporation of Calcutta requires eight electric lorries for conservancy service. The tenders for 5-ton lorries, based on exchange at 1s. 4d. per rupee and subject to exchange variation, were as follows:—Heatly and Gresham (Clayton lorries), Rs.19 863 each, or total for eight, Rs.1 58 904; Jessop and Company (Orwell lorries), Rs.24 524 each, or total for eight, Rs.1 96 272; The Associated British Engineers (Garrett lorries), Rs.30 500 each, or total for eight, Rs.2 44 000; Walford and Company (electromobile lorries), Rs.32 330 each, or total for eight Rs.2 58 640. The tender of Heatly and Gresham was recommended for acceptance, subject to the inspection of the lorries in England by the chief engineer and his approval.

The total number of applications for patents during 1921 was 35 132, which, although 1 540 less than the number for 1920, is substantially more than in any pre-war year. The complete specifications filed numbered 19 159, or 2 637 less than in 1920, the decrease being due to the expiry, on January 10, of the extensions of time granted by the Treaty of Peace with Germany and the Berne Agreement for the filing of applications under the Convention. The number of applications to register designs was 13,387, against 13 669 in 1920, and the number of designs registered was 12 313, as compared with 13 071. There were 11 959 applications for the registration of trade marks as compared with 14 064 in the previous year. Trade marks registered numbered 7 518, an increase of 396 over 1921.

Damages for Tramcar Passenger.

At Hamilton Sheriff Court last week Sheriff Shennan awarded Mrs. E. Wilson £50 damages for injuries sustained while travelling in a tramcar of the Lanarkshire Tramway Co. Plaintiff sued the company and the Hamilton Central Co-operative Society, because the injuries were alleged to be due to a collision between the tramcar and a motor lorry belonging to the Co-operative Society.

The Sheriff Substitute found that plaintiff received a shock to her nervous system from the collision incapacitating her at first wholly and then partially for several months; that the tramcar was being driven carefully and at a moderate speed and the driver was blameless; but that the accident was caused through the fault of the driver of the motor lorry in trying to cross in front of the tramcar when it was within a short distance of the lorry.

Companies' Meetings, Reports, etc.

Oriental Telephone and Electric Company.

In the course of his speech at the annual meeting last week of the ORIENTAL TELEPHONE AND ELECTRIC COMPANY, Sir H. Babington Smith (chairman of the company), who presided, said that the important question of the Indian licences had at last been settled. The negotiations began more than two years ago. The terms, briefly, were that the Government undertook not to exercise their option of purchasing under the existing licence before 1943. If the option were exercised then, the purchase would be on the terms defined in the original licences—that was, on plant value without any payment for goodwill. Conditions were laid down for securing efficiency in the plant and its operation (including the obligation to provide automatic or central battery plant in all exchanges over 200 subscribers). The maximum rate chargeable for an exchange connection within four miles of the exchange had been raised from Rs. 250 to Rs. 350 per annum per subscriber, subject to certain conditions as to periodical revision of the rates, such revision to be on the basis of a standard dividend of 12½ per cent. on the paid-up capital. The rate charged in the past had not, till recently, exceeded Rs. 200. The agreements applying these conditions to the Bombay and Bengal Companies had already been signed. Those relating to the company's branches at Madras and Rangoon were practically settled, and would be signed in the near future. Steps had been taken for organising the Bombay and Bengal undertakings on a new basis, suited to the new conditions, and for raising the capital required for new developments. It was probable that it might be found advisable to form separate Indian companies to take over the systems at Madras and Rangoon.

Mr. Parker Ness had, at the request of the board, made another journey to the East. He left this country last October, and had visited Bombay, Calcutta, Madras, Rangoon, Singapore and Hongkong. Mr. W. W. Cook, the company's consulting engineer, had also gone to India, Singapore and Hongkong for the purpose of advising on numerous questions which had arisen. Mr. Cook was recently appointed by the House of Commons Committee on Telephones to be its technical adviser. He was giving particular attention to the question of the use of automatic exchanges in tropical climates and would advise also on questions of rates and organisation generally as well as on the valuation of the company's plant. The new exchange at Singapore, which had been brought into use in June, 1920, had proved very satisfactory, and the efficiency of the service given was now generally recognised. The Singapore licence extended at present to 1934, and the company had for some time past been in communication with the Singapore Government with a view to a prolongation. Similar questions had arisen at Hongkong, and they had just heard from Mr. Parker Ness that an agreement had been arrived at for an extension of the Hongkong licence to 1955; for a revision of the rates; and for the formation of a local company, the Oriental Telephone Company receiving payment for its property in debentures and shares of the new company. The liquidation of the Egyptian company had at last been completed, and the final distribution of £15 638 had been made by the liquidator.

Shanghai Electric Construction.

Addressing the shareholders at the annual meeting of the SHANGHAI ELECTRIC CONSTRUCTION Co. last week, Sir Alfred Dent, who presided, said that, although the accounts did not show the largest sterling profit in the history of the company, they might be regarded as satisfactory, inasmuch as the operating profit, reckoned on the usual basis of 2s. to the dollar, was larger than ever before. After providing for all expenses there was a disposable balance of £122 361. The loss by depreciation of subsidiary coinage amounted during the year to £93 731, which was rather more than the company's operating profit. Negotiations with the municipal council for extension of the system under railless traction and for additional track facilities were well advanced, and the indications were that a first instalment of extensions would shortly be proceeded with. The traffic pressure was very great, and it was realised that the congestion in the streets could best be relieved by the extensions of the system which were contemplated and by the proposed doublings of the track and improved terminal facilities. The new routes to be developed had at length been agreed upon with the municipal council, but unfortunately they had not reached an agreement on all the terms and conditions. The company were recently approached by the Singapore Electric Tramways Company, and negotiations had been opened with a view to their making arrangements for administering the Singapore system.

Mr. Donald McColl, the company's general manager, said the fact that the volume of traffic had increased from 11¾ millions of passengers in 1909 to 120 millions in 1921, with only a mile and a third of additional route, and was increasing further, so that they were carrying 7 000 000 passengers per mile of route per annum, was evidence of the congestion and of the urgency of extensions. If all the proposed extensions could be introduced to-morrow they would only partly meet existing needs.

An abstract of the accounts was given in our issue of May 19.

Dublin and Lucan Electric Railway.

Mr. J. W. Hill (chairman) presided at the 72nd annual meeting of the DUBLIN AND LUCAN ELECTRIC RAILWAY COMPANY. The report showed that, after providing for debenture interest, and transferring £1 023 from the amount received under the Railways (Settlement of Claims) Act, 1921, there was available £1 339, out of which was recommended the payment of a preference dividend of 5 per cent. for the half-year, absorbing £475 (leaving the cumulative preference dividend six years in arrears). The sum of £864 is carried forward. The chairman said that the British Government had entered into an agreement to pay £3 000 000 in settlement of all claims by the Irish railways, and, out of a sum paid on account, this company had received £2 728. One-sixth of the total sum available would be allocated to the smaller companies to divide amongst themselves. This company, with other smaller companies, was having its interests protected by representation at the Railway Commission, and everything possible would be done to further the interests of the undertaking and the shareholders. The receipts were considerably lower than in 1920, and it was only by transferring a considerable amount from the Government sum referred to that they were able to pay the dividend recommended. Last year, owing to curfew regulations, strikes, coal supplies, etc., the mileage was further reduced, and the number of passengers carried was reduced from 502 719 in 1920 to 387 194 in 1921. With regard to wages, while there had been some reduction, the sum payable was out of all proportion to the revenue of the company, but the directors had no responsibility for it, the huge increases granted during the war being decreed by the British Government.

Electric Construction Co.

The net profit of the ELECTRIC CONSTRUCTION Co. for the year ended March 31 last, after providing £6 131 for debenture interest and £10 000 for depreciation, amounted to £82 685, plus £53 498 brought forward, less provision for excess profits duty for year 1921 (final period), £30 000, making a total of £106 182 10s. Interim dividends paid on November 30, 1921, on the preference and ordinary shares amounted to £11 197, leaving a balance of £94 985, which the directors recommend be appropriated as follows: Final dividend at the rate of 7 per cent. on the preference shares (£2 197); final dividend at the rate of 9 per cent. on the ordinary shares, making a dividend of 7½ per cent. for the year (£13 500); bonus of 2½ per cent. on the ordinary shares, all under deduction of income tax (£7 500); transfer to general reserve fund, which will then amount to £140 000 (£19 715); transfer to dividend equalisation fund (£30 000); leaving £22 073 to be carried forward.

The BRAZILIAN TRACTION, LIGHT AND POWER Co. announce a dividend of 1½ per cent. on the cumulative preference shares to holders of record on the 15th inst.

YORKSHIRE (WEST RIDING) ELECTRIC TRAMWAYS COMPANY announce a dividend of 3 per cent. on the Preference shares for the half-year ending the 30th inst.

A dividend of 1¾ per cent. has been declared by the PENNSYLVANIA WATER AND POWER COMPANY for the quarter ending June 30 to holders of record on June 16.

THE CONSOLIDATED GAS, ELECTRIC LIGHT AND POWER COMPANY OF BALTIMORE has declared its regular quarterly dividend of $2 per share on the series "A" preferred and common stock.

The directors of BRUNNER, MOND AND CO., recommend a dividend on the ordinary shares of 11 per cent. per annum, making with the interim dividend, 8 per cent. for the year, subject to deduction of income tax.

The annual accounts of PERNAMBUCO TRAMWAYS AND POWER Co. show, after providing for debenture interest and transferring £10 230 to capital reserve, and £1 500 to amortisation fund, a surplus of £1 108, which it is proposed to carry forward.

The net profit of J. STONE AND CO. for 1921, after making the necessary allowances for depreciation, etc., was £176 152, making with £52 633 brought in £228 785. The directors recommend placing £25 000 to reserve, paying a dividend of 7½ per cent. per annum on the ordinary shares, and carrying forward £128 755.

The directors of the WESTERN TELEGRAPH COMPANY have declared the third quarterly interim dividend of 5s. per share, free of income tax, for the year ending June 30, 1922, payable to shareholders registered on June 9, being at the rate of 10 per cent. per annum. The transfer books of the company will be closed from June 9 to 16, inclusive.

The profits of the INTERNATIONAL AUTOMATIC TELEPHONE Co. for 1921 were £11 799, plus £634 brought in, making £12 433. Of this directors' fees and dividend on preference shares absorbed £11 790, leaving £643 to be carried forward. A dividend on the preference shares for 1921 has already been paid to the extent of 6 per cent., leaving 1 per cent. to be paid on July 1.

The net revenue for 1921 of the MERTHYR ELECTRIC TRACTION AND LIGHTING COMPANY amounted to £21 074. After deducting administration and general expenses, debenture and other interest, and placing £5 000 to renewals account, there remains £5 002 plus £1 429 brought forward, making £6 431. The directors propose to place £1 200 to reserve, and to pay a dividend of 6 per cent. on the ordinary shares (same as previous year), carrying forward £1 331.

The report of the AUTOMATIC TELEPHONE MANUFACTURING Co. for 1921 shows profit of £28 578, plus £6 861 brought in. After providing for directors' fees (£2 560), debenture interest (£9 567), depreciation on patents, etc. (£3 000), dividend on preference shares

(£12 000), £4 313 remains to be carried forward. Owing to the heavy cost of financing orders due to the high Bank rate and the writing down of stock values, the directors are unable to pay any ordinary dividend.

The accounts of the BRISBANE ELECTRIC TRAMWAYS INVESTMENT COMPANY for 1921 show dividends for the year on shares held by the company £99 933, plus sundry receipts £4 381 and £42 837 brought in, making £147 151. After deducting general charges in London (including corporation profits tax) and expenditure in Brisbane, the net balance was £132 487. After paying debenture interest and preference dividend, the directors recommend a balance dividend of 4s. per share, free of tax, making 8 per cent. for the year, carrying forward, subject to corporation tax, £46 162.

The report for 1921 of the LEWES AND DISTRICT ELECTRIC SUPPLY COMPANY states that the total capital expenditure amounted to £35 919, compared with shares and debenture stock issued to the amount of £32 070. Surplus on working showed a balance of £4 575. After adding interest (£50) and deducting administration and general expenses and remaining items charged against revenue, including debenture interest and provision for £1 750 for renewals, totalling £4 170, there remained £455, making with £1 119 brought in £1 574, which the directors recommend be carried forward.

The net revenue of the DELHI ELECTRIC TRAMWAYS AND LIGHTING COMPANY for 1921 was £22 669. In place of a substantial profit on exchange earned during 1920 there was a small loss under that head during 1921. Profit, after charging general expenditure in London and Delhi and debenture interest, was £18 253, plus £982 brought in, making £19 235, less depreciation of plant and equipment £6 000, renewals reserve, £1 500, reserve for taxation £1 000, leaving £10 735. Dividends of 8 per cent. per annum upon the preferred and participating shares, and 1s. 6¼d. per share upon the ordinary shares are proposed, leaving £530 to be carried forward.

New Companies.

H. Haydon and Co.

H. HAYDON AND CO., LTD. (182 123.)—Private company. Reg. May 29. Capital, £1 500 in £1 shares. Electric light and general electrical engineers, etc. First directors: H. H. Haydon (managing director) and R. Dunn. Secretary: R. Dunn. Registered office: 3, Welford Road, Leicester.

Sunray Ltd.

SUNRAY, LTD. (182 199.)—Private company. Reg. May 31. Capital, £2 000 in £1 shares. Manufacturers of and dealers in electric cables, wires, lines, lamps, and all kinds of electrical plant and accessories, etc. First directors:—J. A. Hartley and C. S. Wallbridge. Reg. office: 196, Greengate, Salford, Manchester.

Breward Sales Co.

BREWARD SALES CO., LTD. (182 055.)—Private company. Reg. May 26th. Capital, £10 000 in £1 shares. Manufacturers, designers and importers of and dealers in electrical plant, house-lighting sets, accumulators, batteries, dynamos, and electric fittings of all kinds, etc. Subscribers: W. A. Anderson and L. R. Shaw. Registered office: St. Margaret's House, 57–59, Victoria Street, S.W.1.

L. McMichael, Ltd.

L. MCMICHAEL, LTD. (182 184.)—Private company. Reg. May 31. Capital, £10 000 in £1 shares. Wireless engineers and contractors, dealers in electrical, magnetic, galvanic and other apparatus, etc. Permanent directors:—Hubert Leslie McMichael, Reni H. Klein, and Armand G. Bloch. Secretary: Leslie McMichael. Reg. office: Providence Place, West End Lane, Kilburn, N.W.

Radiola Wireless Telephone Parts Co.

RADIOLA WIRELESS TELEPHONE PARTS CO., LTD. (182 102.)—Private company. Reg. May 27. Capital, £8 000 in £1 shares. Manufacturers, importers and exporters of and dealers in wireless telephones and telephonic and telegraphic apparatus, parts and accessories, etc. First directors: W. Mansfield and J. F. Little. Secretary: W. Mansfield. Registered office: 17, Brunswick Street, Liverpool.

H. D. Butler and Co.

H. D. BUTLER AND CO., LTD. (182 157.)—Private company. Reg. May 30. Capital, £2 500 in £1 shares. To acquire the business of a wireless engineer and electrical instrument maker and agent carried on by H. D. Butler at 222, Great Dover Street, W., as "H. D. Butler and Co." First directors:—H. D. Butler (permanent managing director) and G. A. Huxley. Reg. office: 15, Queen Street, Cheapside, E.C.2.

South Eastern and Chatham Construction and Power Co.

THE SOUTH EASTERN AND CHATHAM CONSTRUCTION AND POWER CO., LTD. Reg. May 29. Nominal capital, £10 000 in £10 shares. To adopt an agreement with the S.E. Railway Co., the L.C. and D. Railway Co., and the S.E. and C. Railway Companies Managing Committee, and to carry on the business of engineers, contractors for the electrification of railways, tramways or similar works, constructors of generating and transforming stations, suppliers of electricity or other energy, etc. First directors: H. C. Orme Bonsor, Brigadier-General Hon. Everard Baring, Viscount Chilston, Sir William Hart Dyke, Charles Sheath, Sir Alfred Waldron Smithers, P. Crosland Tempest. Solicitors: H. N. Groves, 9 and 10, Railway Approach, London Bridge, S.E. File number 182 131.

Arrangements for the Week.

TUESDAY, JUNE 20th.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

9.0 *a.m. to* 9.45 *a.m.* Assembly at Grand Theatre, Lichfield Street, Wolverhampton.

10 *a.m.* At the Grand Theatre, Wolverhampton Opening of the Convention. Welcome by the Mayor; Presidential address by Mr. S. T. Allen, chief engineer and general manager of the Wolverhampton Electricity Supply Department; paper on "The Extension of the Uses of Electricity for Domestic Purposes," by Lieut.-Col. W. A. Vignoles, borough electrical engineer, Grimsby.

1 *p.m.* Luncheon at the Royal Artillery Headquarters, West Park, Newhampton Road, Wolvernampton.

2.30 *p.m.* Visit to Apley Terrace on the River Severn.

8.30 *p.m.* Reception by the Mayoress at the Art Gallery, Lichfield Street, Wolverhampton.

WEDNESDAY, JUNE 21st.

9 *a.m.* Members residing in Birmingham assemble outside the Queen's Hotel (New Street Station), where the conveyances for Stoke-on-Trent will be in readiness; members residing in Wolverhampton assemble at St. Peter's Steps.

11 *a.m.* In the Assembly Room, Town Hall, Stoke-on-Trent. Paper: "The Administration and Control of Electricity Departments," by Mr. E. Calvert, chief electrical engineer, Finchley. (A visit to Pottery Works will be arranged for any of the ladies or others who do not attend the reading of the paper. Conveyances will be in attendance at 11.15 a.m.)

1 *p.m.* Luncheon to members, delegates, and visitors, by the Stoke-on-Trent Electricity Committee, in the King's Hall, Town Hall.

2.15 *p.m.* Visit to: (1) Central Power Station; or (2) Main Electricity Sub-Stations of the Stoke-on-Trent Corporation; (3) Pottery Works*; or (4) Trentham Gardens direct.

4 *p.m.* Assemble at Trentham Gardens, where facilities for tennis and boating are available.

5.30 *p.m.* Conveyances will leave the Gardens for Wolverhampton and Birmingham.

* The following firms have arranged to conduct parties of members through their works:—Pottery Works—Cauldon Potteries, W. T. Copeland and Sons, Doulton and Co., Ltd., Mintons, Ltd., Josiah Wedgwood and Sons, Ltd.; Engineering Works—The Boving Engineering Works, Cowlishaw, Walker and Co. (1920), Ltd., Kerr Stuart and Co., The North Staffordshire Railway, The Potteries Electric Traction Co.

THURSDAY, JUNE 22nd.

9 *a.m.* Members residing in Wolverhampton should assemble at St. Peter's Steps, where the conveyances for the General Electric Company's Works, Witton, Birmingham, will be in readiness.

9.40 *a.m.* Members residing in Birmingham should assemble outside the Queen's Hotel (New Street Station).

10 *a.m.* In the Main Hall, Magnet Club, Witton. Paper: "Sub-Station Equipment, including Automatic Control," by Mr. R. A. Chattock, city electrical engineer, Birmingham.

11.30 *a.m.* Tour round the various branches of the Witton Works.

(The General Electric Co. have placed their club house, with recreation rooms and grounds, at the disposal of members. An exhibition of domestic and other electrical labour-saving appliances will also be held during the visit).

1.30 *p.m.* Luncheon at the Magnet Club.

2.30 *p.m. prompt.* Visit to Nechells Power Station of the Birmingham Corporation.

3.45 *p.m.* Conveyances will leave Nechells Power Station for the Botanical Gardens, where members will be received and entertained by the Rt. Hon. the Lord Mayor of Birmingham.

5.30 *p.m. prompt.* Leave Garden Party.

7.45 *p.m. for* 8 *p.m.* Annual dinner (evening dress), in the Royal Field Artillery Headquarters, West Park, Newhampton Road, Wolverhampton.

FRIDAY, JUNE 23rd.

9.30 *a.m.* Meeting of the Council in the Grand Theatre, Wolverhampton.

10.30 *a.m.* Annual general meeting in the Grand Theatre, Wolverhampton.

Afternoon. Visit to Wolverhampton Corporation Electricity Generating Station, Commercial Road, when the President (Mr. S. T. Allen) will personally welcome members.

TUESDAY, JUNE 13th.

THE RONTGEN SOCIETY.

8.15 *p.m.* At the Institution of Electrical Engineers, Victoria Embankment, London, W.C.2. Annual general meeting.

Tenders Invited and Accepted.

UNITED KINGDOM.

TYNEMOUTH CORPORATION, June 26.—One a.c. booster. Specifications from the Borough Electrical Engineer.

CADBURY AND FRY JOINT BUYING DEPARTMENT.—Electric cables, fittings and accessories. Specifications from ENM, Cadbury Bros., Bournville.

EDINBURGH CORPORATION. June 20.—Thirty tramcar-top covers. Specification from the Tramways Manager, 2, St. James's Square, Edinburgh.

EDINBURGH CORPORATION, June 12.—Underground insulated cables for twelve months. Specifications from Engineer, Electricity Dept., Dewar Place, Edinburgh.

CHURCH OF OUR LADY OF THE ROSARY, NENAGH. June 17.—Wiring and fitting. Specifications, etc., from Messrs. MacEntee, Lavelle and Gregory, 22, Nassau Street, Dublin.

CLYDE NAVIGATION TRUSTEES. June 12.—Electrical stores, rubber, iron and steel ironmongery, etc., for three, six or twelve months. Specifications from the Superintendent of Stores, 1, Graving Dock, Govan.

PORTSMOUTH TRAMWAYS COMMITTEE. JUNE 13.—Supplies for six or twelve months, from July 1, including insulating materials, overhead line materials. Particulars from the Engineer, Mr. V. J. Lironi, Engineer's Office, Vivash Road, Fratton, Portsmouth.

REIGATE TOWN COUNCIL. JUNE 27.—(1) Diesel engines and single phase alternators; (2) two steel tanks, 20 ft. diameter, for oil storage; (3) 12-ton overhead traveller driven by single phase electric motors; (4) alteration in position of existing cast-iron water tank. Particulars from Mr. C. H. Wordingham, 7, Victoria Street, Westminster, S.W., and 11, Mosley Street, Manchester.

AUSTRALIA.

VICTORIAN STATE RAILWAYS. June 28.—2 687 tons 80 lb. rails, 2 200 tons 100 lb. rails, 224 tons fishplates. Specifications from John Coates and Co., Victoria House, Melbourne Place, Strand. London, W.C.2.

JOHANNESBURG CORPORATION have been recommended to accept the tender of Bruce Peebles and Co. for one 2 000 kW Bruce Peebles-La Cour converter, £10 750.

ABERDEEN Town Council have accepted the tender of the Steel Construction Company, of Glasgow, for the steel work for the first section of the new boiler-house at the electricity works, Ferryhill, Aberdeen, at a sum of £8 113.

GLASGOW CORPORATION has been recommended to accept the following tenders: Carron Co., McDowall, Steven and Co., and R. Taylor and Co., c.i. boxes, section pillars, etc.; Stewarts and Lloyds and Scottish Tube Co., tubes and fittings; Enfield Ediswan Cable Works, Callender's Cable and Construction Co., W. T. Glover and Co., and Craigpark Cable Co., cables; Edison Swan Electric Co., Chamberlain and Hookham, and Ferranti, Ltd., d.c. meters; Beacon Carbons, Ltd., carbons; Edison Swan Electric Co. and Metropolitan-Vickers Electrical Co., a.c. meters; Metropolitan-Vickers Electrical Co., reconstructing car magnetic brake equipments and adding skid-proof attachments; Steele, Turner and Wright, T. Lane and Sons, Alexander and Co., General Electric Co., Simplex Conduits, Ltd., Malcolm and Allan, Wm. Brown and Co., and Alston, Scott and Co., electric fittings and accessories; D. King and Sons, Carron Co., M. McCulloch, J. Allen, Senr., and Son, and Philip and Bruce, lamp pillars.

Electric Ovens for Paint Drying.

The issue of the "Electrical World" for May 27 records a case of economy in the use of electric ovens for drying paint by the Schleuter Manufacturing Company, of St. Louis. An operating economy was obtained in drying paint on light metalware of 12 lb. to 60 lb. per kWh, the extent of the saving depending on the bulkiness of the material handled, and the time of day. Three electric ovens, which are used for drying coloured paints at temperatures varying from 160° to 270° F., were installed in place of large gas and low pressure steam ovens because of their speed, cleanliness and even heat, and the improvement in production has been so satisfactory that the Company proposes to use electric heat for a number of other purposes. The existing ovens are of the standard box or kiln design, with large double doors at one end. The loading is done by hand and the ovens are heated by standard air heaters, placed in the lower side walls. The largest oven has a capacity of 36 kW and operates at a baking range of 270° to 450° F, and four inches of heat insulating material, covering all sides, has been built into it. The two other ovens are of 27 kW and are used for light colour work, at from 150° to 180° F.

A cutting from the "Eastern Province Herald," of Port Elizabeth South Africa, which gives the award of contracts in connection with the Municipal electricity supply in respect of sections a, b, c (part 1), d, and e, may be seen by interested United Kingdom firms on application to the Department of Overseas Trade (Room 49).

Books Received.

"Elektro-Auskunftei." By Georg Heber. (Leipsig: Paul Schulze.) Pp. 754. 10s. net.

"The Year Book of Wireless Telegraphy and Telephony, 1922." (London: Wireless Press.) Pp. lxxxix.+1 477.

"Electric Power Systems." By William T. Taylor. (London: Sir Isaac Pitman & Sons.) Pp. xii.+107. 2s. 6d. net.

"High Voltage Power Transformers." By William T. Taylor. (London: Sir Isaac Pitman & Sons.) Pp. x.+117. 2s. 6d. net.

"Modern Practice in Heat Engines." By Telford Petrie, M.Sc. (London: Longmans, Green & Co.) xi.+264. Price 15s. net.

"Practical Profit Sharing." Reprinted from "The Manchester Guardian Commercial," with Introduction by Seebohm Rowntree. (Manchester: Manchester Guardian, Ltd.) Pp. 67. 1s.

Marconi International Directory.*

The first annual edition of the MARCONI INTERNATIONAL DIRECTORY, BUYERS' AND EXPORTERS' GUIDE, just published, marks a new era in directory publishing and will be welcomed by business men everywhere. The volume embodies many new features and is arranged throughout for quick reference to any item. The Alphabetical Section, which gives the full titles, description of business, full postal and cable addresses, of the leading business houses of the world, is arranged in one complete series instead of providing separate lists for each country or state. Similarly, the Buyers' and Exporters' Guide shows under each trade heading the principal firms in each country engaged in that particular trade, and at one opening one is able to select firms in any part of the world. The time-saving advantages afforded by this arrangement are obvious. Another special feature is the indexes to the Buyers' and Exporters' Guide, which have been translated into five different languages. Not the least important section, however, is the Cable Address Register, by which the sender of a cablegram can be identified when an unfamiliar signature has been used.

We learn from the "Electrical World" that business in ELECTRICAL SUPPLIES in the UNITED STATES is steadily improving, as the result of organised sales campaigns. The orders received are much higher than those of 1913 and 1914 and employment in electrical manufacturing is increasing. The electric light and power companies, the largest market for electrical plant and goods, are ordering large quantities of generating plant, transformers and line material, and at least $400 000 000 will be expended during the current year. This will, in due course, involve the increased use of wires and cables, meters, lamps and other supplies. The general industrial situation is also improving and there is a better demand for motors and switchgear, while the electrification of railroad lines and terminals also promises to bring much work to electrical manufacturers.

* "Marconi International Directory of Cable Addresses, Buyers' and Exporters' Guide, 1922." London: The Marconi International Code Co. 25s. Pp. 1 134.

Prices of Metals, Chemicals, etc.

		Price.	TUESDAY, JUNE 6. Inc.	Dec.
Copper—				
Best Selected	per ton	£67 10 0	£1 5s.	—
Electro Wirebars	,,	£71 10 0	10s.	—
H.C. Wire, basis	per lb.	0s. 10½d.	1/16d.	—
Sheet	,,	0s. 10⅝d.	¼d.	—
Phosphor Bronze Wire (Telephone)—				
Phosphor Bronze Wire, basis	per lb.	1s. 2½d.	1/16d.	—
Brass 60/40—				
Rod, basis	,,	7d.	—	—
Sheet, basis	,,	9d.	—	—
Wire, basis	,,	10d.	—	—
Pig Iron—				
Cleveland Warrants	per ton	£4 15 0	—	—
Galvanised steel wire, basis 8 S.W.G.	,,	£18 0 0	—	—
Lead Pig—				
English	,,	£26 0 0	—	—
Foreign or Colonial	,,	£24 17 6	—	2s. 6d.
Tin—				
Ingot	,,	£154 2 6	£3 0s. 0d.	—
Wire, basis	per lb.	2s. 1½d.	½d.	—
Aluminium Ingots	per ton	£100 0 0	—	—
Spelter	,,	£28 3 9	1s. 3d.	—
Mercury	per bottle	£12 10 0	—	—

Sulphur (Flowers)—Ton £10 15s. *Sodium Chlorate*—Per lb. 3½d.
,, (Roll-Brimstone)—per ton £10 15s. *Sulphuric Acid* (Pyrites, 168°) per ton, £9.
Sodium Bichromate.—Per lb. 5½d. *Copper Sulphate*.—Per ton £26 10s.
Boric Acid (Crystals). Per ton £60.
Rubber.—Para fine, 10d.; plantation 1st latex, 7⅞d.–7⅝d.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd.

COMMERCIAL INTELLIGENCE.

County Court Judgments.

[NOTE.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

BOULT AND CO., Slater Street, Liverpool, electric engineers. £23 4s. 2d. April 6.

HAINE, William Ernest, and BLISSETT, Henry Cornelius (trading as STAMFORD BRIDGE ELECTRICAL AND MECHANICAL ENGINEERING CO.), 495, Fulham Road, S.W. £13 10s. 2d. April 5.

MACAULEY, R. A., 48, Ashton New Road, Beswick, electrician. £30 1s. 2d. April 5.

MESSENGER, Mr. G. V., 26, Edna Street, S.W.11, electrical engineer. £29 12s. 6d. March 29.

Bill of Sale.

[The undermentioned information is from the Official Registry. Up to the date the information was obtained it was registered as given below; but payment may have been made in some of the cases, although no notice has been entered on the Register.]

WILLIAMS, Frederick, The Retreat, County Oak, Crawley, electrical apparatus manufacturer. May 30. £300

RECEIVERSHIPS.

S. GILLITT AND CO., LTD.—A. Dees, of 25, James Street, Newcastle-on-Tyne, ceased to act as receiver and manager on April 29, 1922.

YORKSHIRE INCANDESCENT ELECTRIC LAMP CO., LTD.—J. A. Couper, of Stoney Lea, Ilkley, was appointed receiver on May 24, 1922, under powers contained in second mortgage debentures, dated October 1, 1914.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

CALCUTTA ELECTRIC SUPPLY CORPORATION, LTD.—Registered May 25, supplemental Trust Deed dated May 22, 1922, securing £202 500 debentures with a premium of 2 per cent., present issue £90 000; charged on property as charged by Trust Deed registered November 30, 1920. *£500 000. May 26, 1921.

YORKSHIRE INCANDESCENT ELECTRIC LAMP CO., LTD., Leeds.—Registered May 25, £1 400 and £200 1st debentures part of £6 000: general charge. *£11 400. June 21, 1920.

Satisfaction.

WATSON, MARSH AND CO. (HAMPSTEAD) LTD., manufacturers of electrical apparatus.—Satisfaction registered May 26, all moneys, etc., registered April 21, 1922.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Bankruptcy Information.

COATON, Thomas Green, 16, Humberstone Road, Leicester, under the style of T. G. COATON AND CO., electrical engineer. Receiving order, May 29. Debtor's petition.

GRIEVE, Gideon George, MANGES, Archibald Arthur, co-partnership under the style of THE UP-TO-DATE ELECTRICAL AND MECHANICAL ENGINEERS, 14, West Bute Street, late 236, Bute Street, Cardiff, electrical and mechanical engineers. Receiving order, May 31, Debtor's petition.

Partnerships Dissolved.

DAVIES, Frederick Howell, and ROWE, Edward George, under the style of DAVIES AND ROWE, 119, Dunraven Street. Tonypandy, co. Glamorgan, electrical contractors, by mutual consent, and the business will be continued by E. G. Rowe.

DEARDS, Robert, and CUSDEN, George Augustus, under the style of the ELECTRO METAL CLEANING CO., 86B, South End, Croydon, by mutual consent, as from May 20, 1922. Debts received and paid by R. Deards, who will continue the business.

MARSDEN, Herbert John, and HUTCHINSON, Edward Thomas, electrical, etc., engineers, De Montfort Street, Leicester, under the style of H. J. MARSDEN AND CO., by mutual consent as from March 25, 1922. Debts received and paid by H. J. Marsden.

RODDA, William Duncan, and NEUREUTER, Joseph, electrical factors, 37A, Fountain Street, Manchester, under the style of W. D. RODDA AND CO., by mutual consent, as from May 15, 1922.

Bankruptcy Proceedings.

FRANCIS, William, 4, Prospect Place, Cheam, Surrey, electrical engineer. The first meeting of the creditors was held last week. The statement of affairs showed liabilities £711, net assets estimated to realise £9, deficiency £702. Debtor attributed his failure to losses on contracts and high interest paid to moneylenders. Prior to August, 1915, debtor was employed as an electrician. In August, 1916, he started business as an electrician at his present address, without capital. The business steadily increased until early in 1920, when he made a loss on a sub-contract and was sued by a creditor for £36. He had had recourse to moneylenders. A full set of books had not been kept. Debtor became aware of his position in April, 1920. The case being a summary one, was left in the hands of the Official Receiver as trustee of the estate. The following are creditors:—Southern Electric Co., London, £17; B.E. Co., London, £10; General Cable Manufacturing Co., Leatherhead, £40; Times Electric Co., London, £21.

HILL, George, NOBLE, George, and COWLEY, Edgar, trading as GEORGE HILL AND CO., 22, Chantry Lane, Great Grimsby, electrical engineers. The statement of affairs shows liabilities of £426, and a deficiency of £217. The business was commenced by G. E. Hill and G. Noble in January, 1919, with a joint capital of £200, provided in equal shares. In November, 1920, E. Cowley joined them, bringing in a borrowed capital of £150. Debtors estimated their turnover in 1919 at £1 000, in 1920 at £2 000, and in 1921 at £1 400. No balance sheets had been prepared. They became aware of their position about a year ago. At their public examination last week debtors attributed their failure to losses on contracts, insufficient capital and loss on stock owing to fall in prices.

PRINS, Nathan, late Forest Road, Dalston, N.E.—This debtor, who dealt in electrical accessories, attended at the London Bankruptcy Court recently for public examination on a statement of affairs showing a liability of £143 and assets £7. In reply to the Official Receiver he said that he was a Dutch subject who came to this country in 1912. Before the middle of 1919 he was in employment, latterly with a firm of dealers in electrical appliances, but then began business on his own account as a dealer in electrical accessories. He had no capital, and traded at 74, Forest Road, Dalston, until the date of the receiving order. He had not kept any books of account. Debtor attributed his failure to bad trade and to depreciation of his stock. The examination was concluded.

Catalogues, Price Lists, &c.

We have received from J. C. White a copy of the new addition of the J.C.W. WIRING SYSTEM.

THE "KALEECO" WIRING SYSTEM is the subject of a new illustrated booklet issued by Callender's Cable and Construction Co.

No. 9 of the "TRANSFORMER ABSTRACTS," published by Johnson and Phillips, deals with current distribution with inter-connected star static balancers.

The PORTER PATENT SAFETY SEALS, LTD., of 7 and 9, Belfast Road, Stoke Newington, N.16, have just published, in English, French and Spanish, a new catalogue of their seals for electricity meters, cables, etc.

The ELECTRICAL ALLOY CO. have sent us a copy of their latest publication relating to resistance wires and ribbons used for electric heating purposes. The publication contains a useful set of charts for determining the current carrying capacity of ribbon and strip.

The ENGLISH ELECTRIC COMPANY have recently issued several new publications. Nos. 330, 331 and 332 deal with E.E. cylindrical balanced valves, relief valves, and bucket attachments for impulse wheels; No. 357 with the E.E. camshaft control for electric locomotives; and No. 359 contains an illustrated account of Blackburn (East) Power Station, reprinted from the January number of the E.E. Journal.

We have received an advance copy of a new SECTION (X.5) of the G.E.C. complete CATALOGUE. This list deals with d.c. and a.c. motor starters, and includes full particulars and prices of d.c. face-plate starters of the open, semi-enclosed, totally enclosed cover and totally enclosed types, plain a.c. starters, oil immersed rotor starters, auto-transformer starters and star-delta starters. Complete ranges of starting panels, including switches with fuses, both pedestal-mounted and with angle iron framework, are also given and fully dimensioned line drawings for all types are provided.

Reference Index to Recent Wireless Publications.

We continue below our series of references to recently published articles dealing with wireless telegraphic and wireless telephonic communication.

R.200. RADIO MEASUREMENTS AND STANDARDISATION.

J. M. A Simple Generator of High Frequency Current for Measurement Purposes (*Electrician*, 88, pp. 436-438, April 14th, 1922).
Describes the Elwell 100 W arc with examples of laboratory measurements that can be made with it. Full circuit details are given. R.200.

F. Trautwein. New applications of thermionic valves to high frequency measurements (*Elektrotechnische Zeitschrift*, 42, p. 1 249, November 3rd, 1921).
Abstract of paper read at Physics Congress at Jena. Methods are described whereby two valves with the coils of a differential galvanometer in their anode circuits can be employed to determine the phase difference of two alternating voltages or the scalar product of two alternating currents. R.200.

J. Marsten. Inductance, capacity and resistance of coils (*Wireless Age*, 8, pp. 33-35, September, 1921). R. 200.

M. Chatel. Armagnat's method for the measurement of the wavelength of sustained oscillations (*L'Onde Electrique*, 1, pp. 96-100, February, 1922.)
Gives the theory of a null method of wavelength measurement. R.210.

J. R. Weeks. The Dielectric Constant of Mica (*Physical Review*, 19, pp. 272-273, March, 1922).
Variations from one grade to another of mica found to be due to air films. When carefully split to eliminate air films, and using mercury electrodes, no differences were found between different grades. R.220.

S. Rschewkin and **B. Wuedensky.** The measurement of capacity and high resistances by means of the vacuum-tube generator of intermittent oscillations (*Physikalische Zeitschrift*, 23, pp. 150-153, April 1st, 1922).
The valve oscillator with grid condenser and leak adjusted to periodically interrupt the production of oscillations is applied to measure the value of the capacity and resistance inserted in the grid circuit. R.220/230.

M. Bedeau. The Measurement of the Dielectric Constant of Gases and Vapours by means of sustained waves (*Comptes Rendus*, 174, pp. 380-381, February 6th, 1922). R.220.

R. Ettenreich. Capacity measurements on Antenna Models (*Elektrotechnische Zeitschrift*, 42, p. 1 289, November 10th, 1921).
Abstract of paper describing measurements on small models and a comparison of the two results with those obtained from the formulæ of Austin and Howe. R.220.

R. Whiddington. A Laboratory Valve Method for determining the Specific Inductive Capacities of Liquids (*Proceedings of the Cambridge Philosophical Society*, 20, pp. 445-446, November 10th, 1921).
The method employs alternating electromotive forces of low frequency generated by a thermionic valve. R.220.

L. T. Jones and **H. G. Tasker.** A Braun Tube, Undamped Wave Precision Method of Determining Dielectric Constants of Gases (*Physical Review*, 18, pp. 330-331, October, 1921).
Abstract of paper read before the American Physical Society describing a method of carrying out such measurements in which the small changes of frequencies are observed by a Braun cathode ray tube. R.220.

D. N. Mallik. On the Mutual Induction between two Circular Currents (*Philosophical Magazine*, 43, pp. 604-606, March, 1922).
A mathematical article. R.230.

A. Esau. The inductance of a solenoid of rectangular section (*Jahrbuch Zeitschrift für drahtlose Telegraphie*, 18, pp. 453-457, December, 1921).
A criticism of a formula published by Nirva in the Journal of the Electrical Society of Japan, 1919. The formula gives good results when the ratio of length of coil to length of side of square does not exceed 0·05, and the pitch is not more than six times the diameter of the wire. R. 230.

L. V. King. On some New Formulæ for the Numerical Calculation of the Mutual Induction of Coaxial Circles (*Proceedings of the Royal Society*, 100A, pp. 60-66, October 4th, 1921).
A mathematical paper divided into four sections, entitled respectively (1) note on the direct numerical calculation of elliptic integrals; (2) the scale of arithmetico-geometrical means; (3) application to mutual inductance formulæ for coaxial circles and (4) numerical illustrations. R.230.

J. Wallot. Inductance and Capacity of Single layer coils (*Archir für Elektrotechnik*, 10, pp. 233-256, November, 1921).
An investigation of the experimental results obtained by K. Schäfer which are compared with those of Drude, Gothe, Lenz and others. He comes to the same conclusion that the self-capacity of a coil depends very little on the size of wire and pitch, but mainly on the overall dimensions of the coil. R.230.

J. J. Dowling and **Miss K. M. Preston.** On the Resistance of Electrolytes at High Frequencies (*Philosophical Magazine*, 43, pp. 537-545, March, 1922).
The method employed is similar in nature to that employed in Dowling's ultra-micrometer using three-electrode valves. R.240.

P. O. Pedersen. A Method for the Measurement of R.F. Resistances (*Wireless World and Radio Review*, 10, pp. 135-139, April 29th, 1922).
The method described is based on the use of a quadrant electrometer in conjunction with a special vacuum mercury make-and-break key. R.240.

G. Breit. High-frequency Resistance of Inductance Coils (*Scientific Papers of the Bureau of Standards*, No. 430, Vol. 17; *Journal of the Franklin Institute*, 193, pp. 544-545, April, 1922—Abstract). R.240.

L. Frank. High Frequency Resistance (*Radio News*, 3, p. 932, April-May, 1922). R.240.

J. Erskine-Murray and **B. Williams.** The Determination of the Decrement of a Distant Station by means of a Coil Aerial (*Journal of the Institution of Electrical Engineers*, 60, 3p. 347-351, March, 1922).
A frame aerial at 45° to the bearing of the station is used to obtain a current equal to $1/\sqrt{2}$ of the current in the main receiving coil, for the direct determination of decrement. R.240.

G. L. Addenbroke. The Electrostatic Wattmeter (*Electrician*, 88, pp. 466-469 April 21st, 1922). R.240.

R. R. Ramsey. A simplified method of correcting for the decrement of a Decremeter (*Physical Review*, 19, p. 274, March, 1922). R.240.

N. Grösser. The Damping of two Oscillatory Circuits with Capacity Coupling and a Small Decrement (*Archir für Elektrotechnik*, 10, pp. 257-276, November, 1921). R.240.

F. Trautwein. Measurement of Losses at High Frequencies (*Jahrbuch Zeitschrift für drahtlose Telegraphie*, 18, pp. 261-290, October, 1921).
The method described is a null differential method for determining the losses in a condenser. It is discussed in great detail and numerical data are given. R.240.

H. Pauli. Decrement Measurements with Undamped Oscillations (*Zeitschrift für Physik*, 5, pp. 376-386, 1921; and *Jahrbuch Zeitschrift für drahtlose Telegraphie* 18, pp. 338-347, November, 1921). R.240.

H. Pauli. A New Method of Measuring Decrement with Electric Oscillations (*Zeitschrift für Physik*, 6, pp. 118-126, 1921; *Jahrbuch Zeitschrift für drahtlose Telegraphie*, 18, pp. 348-354, November 1921).
This is an ordinary ammeter-voltmeter method of determining the effective resistance in a tuned circuit. The novelty consists in tuning the voltmeter circuit so that it also takes a pure energy component current; this allows the current taken by the voltmeter to be corrected for as in D-C measurements. R.240.

E. B. Moullin. A Sensitive Direct Reading Voltmeter and Ammeter for High Frequencies (*Wireless World and Radio Review*, 10, pp. 1-6, April 1st; p. 54, April 8th, 1922).
The apparatus described is based on the rectification effect obtained when using a grid condenser and leak. The indicating galvanometer is joined in the plate circuit of the valve. R.250/260.

A. Leontiewa. The Discharge Potential of Small Gaps with Very High Frequency (*Physikalische Zeitschrift*, 23, pp. 32-35, January 15th, 1922).
Experimental investigation of the voltage necessary to spark across gaps less than 0·1 mm. with high frequency oscillations. λ=2-40 metres. For a gap of 0·05 mm it requires 1 000 volts if λ=40 but over 3 000 volts if λ=2 metres. R.260.

R. Mesny. Radiation Measurement (*L'Onde Electrique*, 1, pp. 54-61, January, 1922). R.270.

The Properties and Uses of Micas (*Journal of the Institution of Electrical Engineers*, 60, pp. 339-342 March, 1922; *Electrician*, 88, pp. 446-447, April 14th, 1922—Abstract).
A classification of various grades of micas, with an indication of their suitability for various electrical uses. R.280.

F. Schindelhauer. The Atmospheric Vertical Electric Current in Antennæ (*Physikalische Zeitschrift*, 23, pp. 36-39, January 15th, 1922).
A record of systematic observations of the current in both a high and a low antenna due to atmospheric electricity. R.290.

W. Arkadiew. The Production of Very Short Hertzian Waves of small Decrement (*Physikalische Zeitschrift*, 23, pp. 35-36, January 15th, 1922).
A note on the production of waves of a few centimetres length by means of Hertz oscillator and parabolic mirrors. R.290.

M. Brenzinger. A practical Cathode Ray Oscillograph (*Physikalische Zeitschrift* 22, pp. 491-495, September 1st, 1921).
The H.T. supply was obtained from a transformer, rectifying valve and smoothing condensers. The time axis was obtained by deflecting coils in series with a large inductance, only the lower approximately linear portion of the growth curve was employed. Some photographic results are given. R.290.

F. Zacher. High voltage polar oscillograms by means of a rotating Gehrke oscilloscope (*Zeitschrift für Technische Physik*, 2, pp. 250-256, September, 1921). R.290.

L. Kühn. Wireless Telephony (*Elektrotechnische Zeitschrift*, 42, p. 1254, November 3rd, 1921).
Abstract of paper describing the recent methods of modulation. R.412.

G. Pession. Some Experiments in Radiotelephony (*L'Elettrotecnica*, 8, pp. 617-621, October 15th, 1921; *Wireless World and Radio Review*,, 10, pp. 164-168, May 6th 1922).
A description of tests made with a Poulsen arc with a tuned oscillatory circuit with which the aerial is loosely coupled. The modulation is by changing the resistance in a circuit coupled with the aerial. In some tests four carbon microphones were put in series directly in the modulating circuit; in others, three electrode valves were inserted in the modulating circuit, the grids being controlled by other three electrode valves, the grids of which were coupled up to the microphone circuit. The article is illustrated with diagrams of connections and Gehrke tube oscillograms. R.412.

L. Kühn. A new method for Wireless Telephony with Thermionic Valves (*Jahrbuch Zeitschrift für drahtlose Telegraphie*, 18, pp. 419-452, December, 1921).
The method is the well-known choke control which the author says was developed independently by Huth and Co., of Berlin. Very complete mathematical investigation is given of the necessary magnitudes of the choke coil and condensers. R.412.

J. F. Bront. Some Practical Points on Arc Operation (*Radio News*, 3, p. 701, February, 1922). R.422.

A. Meissner. The Development of Tube Transmitters by the Telefunken Co. (*Proceedings of the Institute of Radio Engineers*, 10, pp. 3-23, February, 1922).
A well-illustrated account of various types of valves of German manufacture, and of various radio installations. R.423.

J. V. L. Hogan. Interference in Radio Signalling (*Radio Broadcast*, 1, pp. 5-8, May, 1922). R.430.

L. Hanson. The Super Differential Circuit (*Radio News*, 3, p. 287, October, 1921).
Combined arrangements of loop and elevated aerial and two loops in different directions are described for eliminating interference. R.430.

H. G. Möller. Selectivity and High Speed Wireless (*Elektrotechnische Zeitschrift*, 42, p 1253, November 3rd, 1921).
Abstract of paper pointing out that the attempt to obtain freedom from disturbance by using almost undamped receiving circuits is inconsistent with high speed signalling at the long wavelengths now employed. R.430.

L. G. Pacent. A Radio System for Simultaneous Sending and Receiving (*Radio News*, 3, pp. 812-813, March, 1922). R.460.

L. Jacquot. Duplex Radiotelephony (*La T.S.F. Moderne*, 3, pp. 4-8, January; pp. 58-63, February; pp. 105-108 March, 1922). R. 460/412.

H. R. Miller and H. E. Hallborg. "Breaking-in" with Amplified Signals (*Radio News*, 3, p. 702, February, 1922). R.460.

Successful Duplex Radio-Telephony (*Elektrotechnische Zeitschrift*, 42, p. 1177, October 13th, 1921).
The German Post Office and the Lorenz Company have carried out experiments between Berlin and Copenhagen, using a 4 kilowatt arc at Königswusterhausen. The Berlin subscriber could not detect that ordinary line telephony was not being employed, except that the loudness and clearness were better than usual. The modulation was done by causing the microphone current to vary the saturation of an iron cored inductance in the antenna, thus affecting the resonance.

H. S. Williams. Harnessing Waves to Wires (*Popular Radio*, 1, pp. 14-21, April, 1922). R.470.

Wired Wireless Telegraphy (*Post Office Electrical Engineers Journal*, 14, pp. 191-194, October, 1921). Notes *re* possible developments. R.470.

J. R. Carson. Radiation from Transmission Lines (*Journal of the American Institute of Electrical Engineers*, 40, pp. 789-790, October, 1921).
A discussion of the radiation of energy from overhead lines used for high frequency wire telegraph transmission. It is concluded that there is no additional attenuation of the current due to this radiation but that the radiation energy losses may be regarded rather as terminal impedances. Formulæ are given for the magnitude of the radiation losses. R. 470/190.

Experiments are briefly described in which a message was magnetically recorded on railway lines and read in the locomotive which was equipped with an amplifier and telephone connected to a coil carried close to the rails. R.580.

D. Wilhelm. United States Radio Network (*Radio Broadcast*, pp. 21-27, May 1922).
Includes charts of U.S. Army and Navy radio stations. R.590.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by Messrs. Mewburn, Ellis & Co., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

Complete Specifications.

144 628 Conners, W. W. Method and apparatus for indicating the geographical location or movement of bodies and for control by wireless. (12/6/19.)
172 349 Charlet, H. Dynamo-electric machines. (2/7/20.)
147 033 Schroter, F. Vacuum-discharge apparatus for the protection of electrical circuits. (29/1/14.)
172 350 Taggart, J. Scott-, and Radio Communication Co., Ltd. Modulation systems for wireless signalling and the like. (6/7/20.)

CONTENTS.

Notes of the Week.

A "Char-à-Banc Convention."

This year's meeting of the Incorporated Municipal Electrical Association, which begins at Wolverhampton on Monday, should go down to posterity as the "Char-à-banc Convention." Owing to the hotel accommodation in Wolverhampton being limited it will be necessary for a proportion of those attending to live in Birmingham, and, for political reasons no doubt, arrangements have also been made for meetings to be held in the latter town and in Stoke-on-Trent. This will make essential the organisation of transport arrangements commensurate with those with which we were familiar during the war, and the convergence of a number of brilliantly painted vehicles on the chosen towns should not only add to the impressiveness of the occasion, but make for an increased pleasantness. Our only regret is that at an electrical convention the electric vehicle should not be in the ascendant. For, favoured by the weather and fostered by that care for comfort which is usual at these gatherings, nothing should be lacking to make the function an entire success, on both the technical and the social sides

Electricity Progress in the Far East.

The Municipal Council of Shanghai have every reason to be proud of their electricity department. It is in a very flourishing condition and excels the most enterprising of British electricity undertakings except perhaps Manchester. And while in 1920-21 nearly 200 000 000 units were sold in Manchester, compared with over 185 000 000 units in Shanghai, this year Shanghai takes for the first time the premier position. On the other hand, owing to the heavy power demands which represented sales of about 117 000 000 units in the past year, and to the exceptionally high load factor of 51·5 per cent., Shanghai possesses advantages which no British undertaking enjoys. The maximum load at Manchester in 1921 was 89 500 kW (against 41 074 kW at Shanghai), and the load factor only 25·46 per cent. But as the past year's net profit at Shanghai was £174 754, of which £104 167 was contributed to the municipal fund, it would seem as if the present tariff is too high; so that when the plant extensions on order are completed the prices should be revised, if not before.

Heavy Power Demands.

During the past year the Shanghai electricity undertaking appears to have made substantial progress in every department. The thermal efficiency of the plant at the power station was improved, three new generating sets were put into commission, about 2 700 additional premises (representing 10 519 kW) were connected to the mains, and nearly 41 000 000 more units were sold. Though the new power demands were not as great as were anticipated, yet the sales were over 38 million units more than in 1920; and as local industries are now being consolidated on a permanent basis, there will, no doubt, be a steady increase in the output for power for some years.

The Domestic Load.

We are also glad to notice that a substantial advance is recorded in the electric heating and cooking demands, notwithstanding the relatively high rates for these services. There was a particularly brisk demand for heating and cooking apparatus on hire, and though largely augmented stocks of radiators were carried by the Department, the requirements of customers again exceeded the supply, 1 769 radiators having been issued during the year. The result of the policy in increasing the size of hired radiators

from 2 to 3 kW has been justified, for the larger size is almost invariably selected by consumers. The Department, which is not hindered by the legislative restrictions on hire-purchase which prevail in this country, also let out ranges, motors and other apparatus on hire. Though the customs of the Chinese cook are said to impose a heavy handicap upon electric cooking progress, nevertheless a real advance was made. The hiring and showroom facilities of the Department are much appreciated and have greatly assisted in the rapid development of electricity for power and domestic purposes. We would like to see every electricity authority in this country equally well equipped for meeting prospective consumers' requirements. Meanwhile Mr. ALDRIDGE is to be heartily congratulated.

Are Two Public Inquiries Necessary?

DRAFT Orders constituting two Electricity Districts have recently been issued by the Commissioners, and the second public inquiries will take place later in the month. In both the districts concerned, South-East Lancashire and the South-West Midlands, it is proposed to set up Joint Advisory Committees in place of the Joint Authorities suggested in the Electricity (Supply) Act, but the chief point is of what use is further inquiry. The position was thoroughly investigated at the first hearing, and though there is a statutory obligation to hold a second inquiry after the adoption of a scheme and the preparation of the draft Order, it is only a waste of time and money. We therefore hope that if the second inquiry must be held and is protracted, those responsible will be compelled to pay for it.

A Contrast in Committees.

IN both cases some slight adjustments of the proposed areas, and some small amendments of the original schemes have been made, but each district gets substantially what apparently the majority of the authorised distributors want. That is, South-East Lancashire is to have a cumbersome Advisory Committee of about 50 members, who will, however, be dependent upon a much smaller committee of engineers; and in the South-West Midlands there will be a small Advisory Committee of four, two appointed by Birmingham Corporation and two by the Shropshire, Worcestershire and Staffordshire Electric Power Co. There could scarcely be a greater contrast in method, but then the economic eccentricities of Lancashire had to be placated and the peculiar position of the South-West Midlands taken into account.

Powers of S.-W. Midlands Committee.

THE South-West Midlands Order does not appear to confer many advantages or enlarge the powers of the authorised undertakers much beyond those already authorised by the Electricity Acts of 1909 and 1919. It does, however, define the spheres of influence of the Birmingham Corporation and the Shropshire Co., sanctions three agreements to safeguard the interests of the Leicestershire and Warwickshire Electric Power Co., and of the Worcester and Malvern Councils, and lays down rules for the constitution of the Committee of four, two of whom, we are glad to notice, are to be the chief engineers of the Corporation and company respectively. Three members are to form a quorum, and as the chairman, who is to be elected from amongst the members of the Committee, will not have a casting vote, there may be occasions when no decision can be arrived at. In this event the Committee must report to their principals who, if they cannot agree, are at liberty to submit the matter to the Commissioners for their decision. The Committee's functions are to be purely advisory, and are concerned with the operating timetable of the interconnected generating stations, the best load factor obtainable, the conservation of fuel, the proper return upon capital, the standardisation and regulation of supply, and any other matters that may be referred to it. All this seems to be vague and very general, but we have no doubt that the engineers of the parties will "carry on" without much assistance from the Commissioners being necessary.

That Cheap and Abundant Supply.

WE notice that it is solemnly laid down "it shall be the duty of the Corporation and the company to secure the provision of a cheap and abundant supply of electricity in the District." It is time this clap-trap about cheap and abundant supplies, so dear to ignorant politicians and to popular newspapers, was stopped. It is clearly to the advantage of both undertakings to supply as cheaply and efficiently as possible, and they would have done much more than they have if legislative restrictions had been earlier abolished. Even now the Commissioners can help materially by removing the obstacles to the use of overhead transmission lines, and thus getting rid of the restrictions upon expansion in rural areas, a matter of which a correspondent this week emphasises the importance.

Undue Preference in Methods of Charging.

WE imagine that the recent revival of allegations of undue preference may be ascribed to the increased charges for electricity which have become necessary since the war. Naturally, no one wishes to pay more than he is legally bound to do, but it is clear that charges of unfair preference are more easily made than proved, as shown by the judgment in Westminster Electric Corporation *v.* Wykeham Studios, Ltd., which we reported recently. Though this decision appears to be in conflict with the judgment of a Divisional Court in Linsdell *v.* Paignton Electric Light Co. it is substantially just and in accordance with previous judicial pronouncements upon the construction of sections 19 and 20 of the Electric Lighting Act of 1882, the basis of all methods of charging

The Legal Position.

BY section 19, where a supply of electricity is provided in any part of an area for private purposes, then, generally, every consumer is entitled to a supply on the same terms to which any other consumer is entitled *under similar circumstances* to a corresponding supply. By section 20 the undertakers must not, in making agreements for the supply of electricity, show any undue preference to anyone, and though they may make such charges as may be agreed upon, these must not exceed the limits set out in their Order. These clauses seem to be quite clear and sufficiently elastic for all purposes.

An Important Phrase.

INCIDENTALLY, it is well to remember that there is no reference in them to light or power, but only to electricity Light, power, traction and heating are later distinctions introduced by electrical engineers as the applications of electricity have expanded. In dealing with electricity tariffs many consumers seem to ignore the important phrase, "under similar circumstances," but it must be recollected that this has received a liberal judicial interpretation. It

has been held to embrace the amount of energy consumed, the expense of supplying and getting payment, the uniformity of the demand, and the time when the energy is required. Consequently different charges have been authorised for lighting power, heating, traction and other purposes, according to the load factor, diversity factor and other factors affecting each particular class of consumer. It is satisfactory to see, therefore, that the present judgment is based upon, and professes to maintain, these principles.

Is Electricity for Photographic Lamps Power?

One class of consumers—*viz.*: cinema theatres—will be specially interested in the judgment of Mr. Justice Swift, for it has decided that electricity supplied for photographic lamps is power and not light. As the contrary was held, we think rightly, in the Paignton case in 1920, all electricity authorities will now be called upon to give power rates for the supply to cinema lanterns where they have been charging at lighting rates. We have always contended that the cinema load is so good that special terms should be given to this class of consumer. As a matter of fact, many supply undertakings have introduced a scale intermediate between lighting and power for cinemas, and we hope that where this has not yet been conceded the matter will now be reconsidered. At all events, we should deprecate more litigation on the subject, because it will benefit no one but the lawyers, and will engender friction between the supply authorities and their consumers.

The Inefficiency of the Domestic Range.

The Fuel Research Board has published the results of a scientific investigation into the efficiency of domestic ranges and cooking stoves. Readers of The Electrician will not be surprised to learn that Mr. A. H. Barker, who made the tests upon which the report is based, finds that to design a range to do several things is only relatively economical, when it does all those things at once, and is most uneconomical, when it is only doing one at a time. At best the total efficiency figures only lie between 5 and 11 per cent., while in apparatus designed to do only one thing 30 per cent. is easily obtained. But with a range used for one purpose alone at a time efficiencies as low as 1 per cent. were obtained, the average being only 2½ per cent. It is not stated whether these tests were made with new equipment, but they probably were, and, as is well known, the efficiency of ranges, for reasons connected with the deterioration of the brickwork, cleaning and fixing, falls off very much with use. To overcome this waste it is suggested that a central (or rather communal) heating and water supply should be used even in cottages, as has been successfully done in the United States.

One Job, One Apparatus.

We need hardly say that we consider that matters ought to be carried a great deal farther than this. Without descending to propaganda, in which we are too modest to indulge, the policy in domestic life should be to use specialised apparatus of the most efficient kind for performing one operation and one operation alone. When it is not in use that apparatus should not be consuming fuel. Continuous fuel consumption to little purpose, apart from other considerations, is one of the gravest disadvantages of the kitchen range. To adopt our policy would mean labour saving as well as fuel economy, two objects which are well worth striving for in these stressful days.

Physical and Physiological Aspects of Science.

The Annual Report of the Council, presented at the meeting of the Illuminating Engineering Society on May 25, showed that the Society has of late had much to do with physiological aspects of illumination. The Presidential Address delivered by Sir John Herbert Parsons, who is an eminent ophthalmic surgeon, contained some happy allusions to the need for co-operation of scientists in dealing with that borderland between physics and physiology. For the scientific treatment of a physical problem measurement is a necessity. Advances in methods of measuring illumination have had much to do with progress in the art of artificial lighting, and in the field of natural lighting (notably the conception of the "daylight" factor attributed to Mr. A. P. Trotter) measuring instruments have also proved of value. But physicists too often forget that the basis of physical measurements is biological. The so-called "outer world" only exists for us by virtue of the sensations it arouses in our bodies, and physical measurements are open to the errors of all human observations. In the case of photometry, especially in the comparisons of sources of light which differ in colour, we soon become acutely conscious of the influence of personal error, which we can eliminate only by some system of averaging. Similar considerations arise in connection with the much-discussed problem of glare, to which Sir John also made allusion. We have at present been compelled to resort to practical compromises, such as those embodied in recent reports of the Departmental (Home Office) Committee on Lighting in Factories and Workshops. But there is still a great deal to be done on a joint physical and physiological basis before we can claim to have disposed of the problem in a scientific manner.

British Electric Traction Company.

Seeing that all tramway undertakings of the country have been experiencing a lean time, the British Electric Traction Co., the bulk of whose revenue is still derived from provincial tramway and transport enterprises, are to be congratulated on the results of the past year's working. For though the gross revenue was £262 900, a drop of about £22 000, the net revenue of £134 000 was only £1 000 less than in the previous year, so that expenditure must have fallen in a slightly greater ratio than receipts. An ordinary dividend of 4½ per cent. is recommended, compared with 4 per cent. last year, and, after placing £14 700 to reserve the amount carried forward is £194 200, though this is subject to three years' Corporation Profits tax. We notice that the company's investments, which now stand at £3 987 600, or £125 800 more than the preceding year, are spread over a variety of home and foreign securities, and that the average yield has fallen from 5·39 to 5·24 per cent. The tendency of the company appears to be to widen their sphere of operations, for a number of the new investments are unconnected with electric traction. This portion of the business has so far been quite successful, though some of the foreign Government securities in the list look a little risky.

Electric Power Demands in Lancashire.

One of the modern tests of the industrial progress of a district is the amount of electricity used in it for power purposes. If we judge the area supplied by the Lancashire Electric Power Co. by this standard, Lancashire enterprise cannot be in so bad a way as is sometimes represented. For the company generated (or purchased) nearly 63 000 000

units during the past year, compared with 60 686 500 in 1920, and the connections increased from 44 000 H.P. to 54 700 H.P., by far the highest figure for any year since the company commenced operations in October, 1905. The gross receipts and trading profit also showed a striking improvement, being £294 900 and £94 300 respectively compared with £249 900 and £47 400 in 1920. All the company's financing is done by the Lancashire Electric Light and Power Co., which has raised £800 000 in debenture stock and preference shares during the past two and a half years. Moreover there seems no reason why the company should not do still better once trade begins to revive.

Efficiency of Wireless Watchers.

THE findings of the Merchant Shipping Advisory Committee, which was appointed to report on the efficiency of "wireless watchers" and on the sufficiency of Sec. 1 (2) of the Merchant Shipping Wireless Telegraphy Act of 1919, are singularly lame and inconclusive. Though many witnesses were examined, the Committee state that the time at their disposal was not sufficient to enable them to investigate thoroughly the cases of alleged inefficiency of watchers. But they consider that even if the allegations should, on further inquiry, be sustained they do not afford grounds for altering the present regulations. The logic of this statement is difficult to understand and appreciate. An inefficient watcher is obviously a source of danger to all on board under the present requirements, but in any event the procedure involves delay as recent accidents at sea have shown. Watchers, whose employment cannot be much more economical than wireless operators, should either be thoroughly efficient or else be replaced by men with qualifications of the latter. We hope the Board of Trade will take steps to alter the regulations accordingly.

The Limitations of Broadcasting.

THE "broadcasting boom" shows no signs of diminution. Amateurs are still being pressed to invest in receiving sets, and instructed often with more enthusiasm than wisdom in their use and possibilities. Generally we have nothing to say against this, as it will be of both direct and indirect advantage to the electrical industry. There is, however, a possibility of having too much of a good thing, and when the suggestion is made that the broadcasting can be usefully employed for tracking and capturing mobile criminals that stage has been reached. We have no expert knowledge of criminal psychology, but such authorities on the subject as Sir ARTHUR CONAN DOYLE, MR. WM. LE QUEUX and Mr. JOHN BUCHAN lead us to suppose that operations of this kind are best conducted in secrecy. Now secrecy is no quality of broadcasting, and, as Sir CHARLES BRIGHT rightly points out, to distribute information of this kind by wireless means is more likely to lead to the criminal's escape than to his capture.

The "Commemoration Journal."

THE Commemoration Number of the "Journal" of the Institution of Electrical Engineers, which has just been issued, contains not only a full account of proceedings at the meetings which took place in February, but a number of additional communications from well-known pioneer members, and a series of photographs of both human and historical interest. The whole forms a record of enterprise, high endeavour, faith, with sometimes consummation and sometimes failure as their result, and generally a record which is tinged with humour, pathos, and human interest. It is a record to be read, studied and preserved. In fact, if any electrical engineer is on the look-out for a bedside book, he might do a good deal worse than take this number for that high purpose. For he will find in it qualities which give a quiet mind and lend rest after toil to the weary soul.

The Standardisation of Cooker Types.

WE have always protested against the too early standardisation of electrical apparatus. For, if not in its infancy, our industry is still young enough to make it wise to use every effort to avoid grooves, whether in policies or in more material things. At the same time ultimate standardisation should ever be kept in mind, and an immediately useful way of doing this is by a close and continued examination of all parts of the apparatus so that weak features can be eliminated or improved.

One Type, One District.

THIS is particularly necessary with cookers, and indeed with all domestic electric apparatus, and a step towards this end might be made by electricity supply engineers arranging to use only one type of cooker in their districts. In this way not only would they and their staffs become experts in the qualities of that particular type of apparatus, but consumers would be relieved from an embarrassment of choice, salesmen from embarrassment of another kind, and stocks of spares reduced to a minimum. The argument against this policy is that it is difficult to make the choice, and that specialisation is as necessary to avoid as standardisation. But no cooker on the market at the present time is of outstanding merit, while equally none outstandingly lacks merit. And supply engineers do meet for discussion from time to time when notes can be compared. Now, when the domestic load is growing, is the chance for taking what should be a useful step.

U.S. Power Station Practice.

CONSCIENTIOUSLY to attend the Annual Convention of the National Electric Light Association must be a devastating experience, both mentally and physically. Commenting on the proceedings of this body two years ago we pointed out that no less than twenty-one papers were down for reading, while seventy-three reports were to be presented for discussion. In addition there were the usual dinners, municipal welcomes and social functions which, though a change from the more technical labours, are equally tiring. At this year's convention, held at Atlantic City last month, the figures, though we have not actually taken a census, must be quite as large, and we are not therefore surprised to find the opinion growing that the whole proceedings are too gargantuan to be useful. For not only are the programmes of the various sessions overcrowded, but, two or more sessions being held in parallel, it is difficult for even the most energetic to get the full benefit from them.

The Better Way.

WE cannot help thinking, therefore, that ours is the better way. To take this year's I.M.E.A. Convention as an example. Three papers only, all on important subjects, are to be discussed; and the time provided for this purpose is adequate, if not generous. The social functions and the visits to works are not too numerous or too exhausting, and there will therefore be no excuse for anyone attending not taking his or her full share in every item in the programme. On the other hand, there are conventions even in this country where the programme is over

crowded. We hope that when the British National Electrical Convention comes into being the better example will be followed. For there is such a thing as mental gourmandising with its consequent ill-effects.

Turbine Performances.

In making these criticisms we have no wish to minimise the usefulness of the information published at the National Electric Light Association's Convention. Some of the reports, which represent a year's calm work, should be especially interesting to electrical engineers in this country. For example, the Prime Movers Committee gives data of the performance of seventy-eight turbines with outputs of from 20 000 kW to 45 000 kW. This data shows that much has yet to be learned in the design and manufacture of these large units before finality can be said to have been reached. At present breakdowns are frequent and lengthy. In the case of one 35 000 kW machine running at 1 500 revs. per min., the period during which it was shut down for various purposes amounted to no less than 47·2 per cent. of the total time in service, while in the case of a 20 000 kW machine also running at 1 500 revs. per min. it was 32·6 per cent. It is only fair to say that in several other cases the ratio of time in use to total time was extremely high ; nevertheless we think the committee are justified in stating that 100 per cent. availability of generating equipment is essential from a service standpoint, and that as existing units do not approach this figure it would generally be better to invest money in improving their reliability than to arrive at the same end by purchasing reserve units.

The Question of Turbine Size.

A correlated question is the best and most economical size of turbines for large generating stations. In this country we seem to have become crystallised round about 15 000 kW or 20 000 kW, and it is doubtful whether on the balance anything is to be gained by going much higher. The very large machines now in use in the United States, as Mr. Patchell, among others, has shown, have their own peculiar disadvantages, while the fact that in many cases they cannot be fully loaded for a great part of their life will, we hope, combine to limit their use over here.

Boiler House Practice.

The same might be said about boiler house practice. In the States the trend seems ever upward, a boiler with a normal rating of 2 982 h.p. having been installed in the Congress Street heating plant of the Detroit Edison Company. In this country it may be said that we have gone far enough. In the United States, as over here, there is a continued tendency towards higher pressures, the present maximum being 350 lb. with a steam temperature of 700° F. This compares with the steam pressures of 270 lb. and 300 lb. at Runcorn and Edinburgh, where the total steam temperature is about 700° F. Rumour hath it, however, that the New North Tees station is to show us something extraordinary in this respect.

Boiler House Economics.

As Mr. Mitchell pointed out in his Paper on the Dalmarnock station, read before the Summer Meeting of the Institution of Electrical Engineers, the place where economics in generation are now to be primarily sought for is in the boiler house. A careful record of results is one of the most important means of achieving this end. But equally important is the careful design of the equipment employed and a rigid examination of the materials used in manufacture and of the effect of these materials on the initial and ultimate performance of the plant. Working on these lines, attention has been given by the Prime Movers Committee to the study of refractories both as regards temperature effects and mechanical strength, with a result that the specification of the Panama Canal Commission for firebrick has been recommended for use.

The Auxiliaries Problem.

The problem of how most economically to drive the power station auxiliaries is one that is much exercising the minds of electricity supply engineers in this country. Here again we may obtain some useful hints from the Prime Movers Committee's report. Reliability, they insist, quite rightly, is the first essential, and it is also essential that the equipment should be in duplicate. Otherwise there seems to be as great a variety of practice as in this country. The house turbine is the favourite method to employ either in conjunction with steam-driven sets or with an emergency electric drive for the main bus bars. A third course is to bleed the main turbines to supply the auxiliary steam drive. It is pointed out that theoretically the greatest economy is gained from multiple stage bleeding of the main unit, but that practical operation has limited the bleeding points to two. It is interesting to note the recommendation that the control of the auxiliaries should be in the hands of one man who should be responsible for maintaining a heat balance at all times. There is no question that the proper operation of auxiliaries has a most satisfactory downward effect on the coal consumption per unit generated, and if the introduction of a psychological factor is likely to assist economy it is certainly worth trying.

Other Useful Reports.

In examining at some length the findings of the Committee on this important subject we have been obliged to neglect other reports which are of almost equal interest. These include one on electrical apparatus to which we shall hope to refer in a later issue, as it includes an important discussion on the rating of circuit breakers and automatic substation practice ; another on inductive interference, on which subject agreement has apparently been reached between the electricity supply and telephone authorities, and particularly a mass of information relating to merchandising finance and selling. These reports all show that electrical engineers in the United States are fully alive to the possibilities of the commodity with which they have to deal. They equally show that there is much to be done before that commodity has that universal application which is its right.

A Poll—and its Result.

As an example of this we may quote one incident at which we were more than a little relieved. At a meeting of the merchandising section a count was taken of the number of men in the room who used electric ranges in their own homes. There were twenty less than 10 per cent. of the audience. We really thought they were more progressive in the United States. What would be the result of a similar poll at one of the meetings of the I.M.E.A.—say when Colonel Vignoles' paper on "The Extension of the Use of Electricity for Domestic Purposes" is read next week? But even about this backwardness we may be optimistic, for it shows what a vast deal yet remains to be done, and that electrical engineers at least will not need to look for work just yet awhile.

Considerations Relating to the Design of Oil Circuit Breakers.

By D. R. DAVIES, A.M.I.E.E.

In the first part of the article the author discusses the methods usually adopted for reducing the losses in oil circuit breakers. Information is also given which can be used for estimating the maximum temperature rise of small conductors during short circuit. Such information is, of course, quite applicable to potential transformer connections or the like.

The interruption of alternating current is now almost universally accomplished by means of the oil circuit breaker, and although air break types are used both on the continent and in America, they are only to be found on small subsidiary circuits.

The disadvantages of the air break switch are :

(1) The length of time during which the arcing lasts.
(2) The uncertainty of breaking all three phases simultaneously.
(3) The amount of space required when used indoors.
(4) Impossibility of breaking very heavy currents.

Certain test results for this type of switch were published in the "General Electric Review" for September, 1914, and the average arcing time is given there as about six seconds, whereas in a good oil switch it would probably not exceed half a cycle.

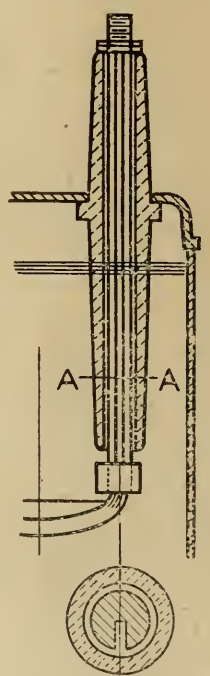

FIG. 1.—SHOWING METHOD OF REDUCING EDDY CURRENT LOSS.

Although the use and manufacture of the oil circuit breaker has been in vogue for the past twenty years, there is still a dearth of reliable information concerning the behaviour of arcs in oil, and consequently designers must rely to a certain extent upon semi-empirical data, derived from tests on existing breakers. An inspection of most recent designs will show that, in the way of tank strength, air chamber, and head of oil, modern breakers are more liberally proportioned than their predecessors. Electrical operation is now the recognised system adopted for central station oil circuit breakers, and to a smaller extent for sub-station work; in fact it would be impossible to close manually some of the larger sizes of breaker with the rapidity necessary for synchronising.

Current to be Dealt With.

The current that must be interrupted under fault conditions greatly exceeds the normal load current, and oil circuit breakers therefore have a normal rating, and a short circuit rating, commonly called the breaking capacity. Breaking capacity may be defined as the maximum kilovolt-amperes which the circuit breaker can break under prescribed conditions, at stated intervals, a specified number of times. The value of the maximum kilovolt-amperes is the product of the rated working pressure in r.m.s. kilovolts, and the actual r.m.s. current at the time of separation of the contacts, multiplied by 1, 1·73 or 2, for single-phase, three-phase or two-phase systems respectively.

The short circuit rating is by far the more difficult one to meet, and is the one mainly responsible for the size and cost of the breaker. It must be remembered, too, that in the case of large breakers there is not the same opportunity for testing the ability of the breaker to fulfil this rating before going into commission as is the case with other electrical apparatus.

The class of service for which a breaker is intended determines to a great extent the amount of consideration that must be given to certain features. Breakers having short circuit ratings up to about 50 000 kVA enjoy a more extensive market than larger sizes, and their manufacture on mass production principles must therefore influence the designer in his conclusions.

Heating during Normal Conditions.

During normal operation the maximum temperature rise should not exceed the following limits :—

(*a*) For breakers rated up to and including 2 000 A, the temperature rise should not exceed 30 deg. C.
(*b*) For breakers rated above 2 000 A, the temperature rise should not exceed 40 deg. C.

Although no difficulty is experienced in keeping within these limits on breakers intended to carry less than 1 000 A, more attention must be paid to heavier currents in order to avoid trouble due to local heating.

The losses occurring during normal service are :

(1) Copper loss (I^2R) in contacts, stems, etc.
(2) Iron loss in top cover and tank walls.

Contact stems intended for currents of the order of 2 000 A may either be built up from a number of copper straps in parallel, or solid round rod may be used. Although the use of straps is undoubtedly desirable for keeping down the heating, such an arrangement lacks the requisite stiffness, and is difficult to insulate at the point where it passes out through the top cover. This is mainly the reason why strap conductors are more suitable for breakers where their length may be comparatively short, and the voltage low. On the other hand, round rod permits the use of porcelain insulators, and also makes a sound job mechanically. It is well known that conductors offer a greater resistance to the flow of alternating current than they do to direct current, owing to the skin effect. By referring to Table 1 it will be seen that when conductors as large as 2 in. diameter are used on 50 period circuits, this increase in resistance becomes quite appreciable.

TABLE 1.

Diam. in.	Ratio $\frac{\text{Resistance A.C.}}{\text{Resistance D.C.}}$
1·00	1·09
1·25	1·18
1·50	1·38
1·75	1·60
2·00	1·75

Another cause of heating in large solid conductors is due to the eddy current loss, and, as this loss increases as

the fourth power of the diameter of the conductor, the heating increases very rapidly. Therefore, when solid conductors as large as 2 in. diameter are used it is necessary to have a small slot milled down nearly its entire length as shown in Fig. 1.

Heating Precautions Unnecessary for Small Currents.

Generally speaking special precautions to prevent heating due to iron losses are unnecessary on breakers designed to carry less than about 350 A. Larger currents, however, demand certain modifications to the top cover, and the designer must either introduce short air gaps into the magnetic circuits, or else specify the use of non-magnetic metal.

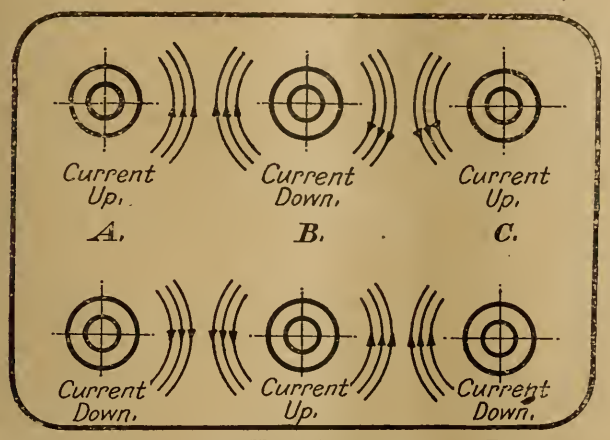

FIG. 2.—SHOWING HOW HIGH FLUX-DENSITY IS PRODUCED BETWEEN PHASES.

Fig. 2 shows the plan of a typical small breaker, and it will be noted that at the particular instant of time when the current in phase B is at its positive maximum, that in phases *A* and *C* is half the negative maximum, so that when the normal load exceeds about 350 A the flux-density becomes great enough to heat up the top cover unless the usual precautions have been taken.

The heat generated in the oil is conveyed by convection currents to the tank side, from which it is then dissipated by radiation to the surrounding atmosphere. In order to assist the oil to circulate in the tank it is essential that :

(1) An oil layer be left between the lining and the tank wall.
(2) The top edge of the lining is beneath the oil surface.
(3) The lining is arranged so that it can only rest on the tank bottom at certain places.

A further advantage of allowing these spaces is that, the oil being in direct contact with the tank side, the heat flux is not constrained to pass through the lining before reaching the tank wall, and the temperature gradient is therefore uniform.

Circuit Breakers for Furnace Equipments.

The rapid development of the electric furnace during the war created a demand for very heavy current breakers for low voltage service. As the heat developed in this type of breaker is great in comparison with the mass of oil and the area available for radiation, certain special features must be incorporated in the design, such as, for example, the corrugated tank, non-magnetic top, or even perhaps the main brushes may be mounted outside, the arc tips only being immersed in small oil tanks.

Heating of Conductors during Short Circuit.

So far the heating of the copper contact stems due to the passage of the normal load current only has been considered, and, even when breakers are intended to interrupt currents of the order of 30 000 A r.m.s. the thermal capacity of the stems is always sufficient to prevent any excessive rise in temperature, although their sectional area may have been determined from the point of view of the normal current carrying capacity only.

Even in an extreme case, where a purchaser would require a breaker capable of carrying, say, 300 A normally, and to interrupt 30 000 A on short circuit, it is very doubtful whether any manufacturer would offer a breaker having a normal current rating of less than 600 A.

The cost of the copper is only a small percentage of the total cost of a large breaker, and from the manufacturer's point of view the saving effected by a design with a normal rating of less than 600 A does not really justify carrying the extra number of parts in stock.

Generally speaking, a breaker having leading-in stems not less than $\frac{7}{8}$ in. diameter is quite capable of dealing with 30 000 A, during short circuit conditions, without producing a temperature rise sufficient to cause damage. We can say, then, that to a certain extent the area of the leading-in stems is independent of the short circuit rating of the breaker.

Design of Arcing Contacts.

When we come to consider the design of the arcing contacts, however, the conditions are very different, and the flimsy pieces of copper which are sometimes provided for this purpose are wholly inadequate for their duty. It is important to remember, when designing arcing contacts, that the sectional area and contact area are both functions of the short circuit current only, and both are therefore entirely independent of the normal load current of the breaker. Arcing contacts which are intended to carry currents of the order of 30 000 A or more during the arcing period should receive special consideration, and anything in the nature of flexible shunt leads should have an ample sectional area, or the danger of fusing them is always present.

Temperature Rise.

The following information, together with the curves, Fig. 3, will enable those interested readily to determine the temperature rise obtainable under the worst possible

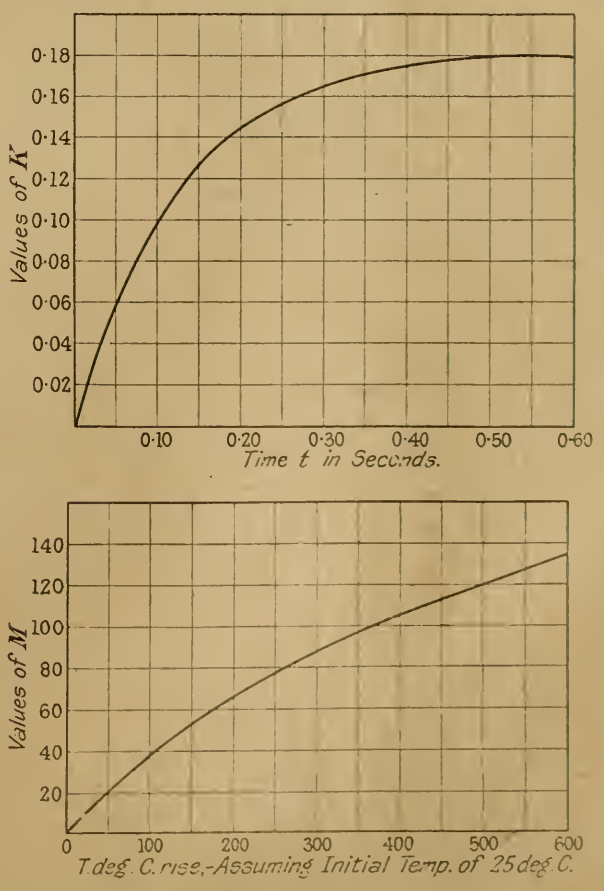

FIG. 3.—HEATING OF CONDUCTORS ON SHORT CIRCUIT.

conditions, *i.e.*, when a breaker is closed on an incipient

fault which develops at the instant at which the arcing contacts separate.

Let t = time in secs. from moment of short circuit.
T = temperature rise in time t (in deg. C.).
i = instantaneous value of the current.
α = temperature co-efficient of copper per deg. C. = 0·428.
A = cross-section of conductor in sq. cms.

Then, neglecting the heat radiated, the necessary condition is :—

$$A^2 = \frac{2\int i^2.dt \times 10^{-7}}{\frac{1}{\alpha} log_{10}(1+\alpha T)}$$

The value of i^2 depends upon the machine constants and the point of the voltage wave at which the short occurs. If we assume that the current falls to about one-half its initial value I in 10 cycles then we can write $i^2.dt = 2I^2 \times K$ where K is given by the curve (Fig. 3), and I is the r.m.s. value of the first alternation.

These values of K are based on the machine damping constants generally found in practice. Substituting for $i^2.dt$ in the above equation we obtain

$$A^2 = \frac{2I^2 \times K \times 10^{-7}}{\frac{1}{\alpha} log_{10}(1+\alpha T)}$$

or

$$M = \frac{2I^2 \times K \times 10^{-7}}{A^2}$$

Where

$$M = \frac{1}{\alpha} log_{10}(1+\alpha T)$$

Values of T corresponding to those found for M may be obtained from the curve, Fig. 3.*

Not only must the sectional area of the shunt path through the arcing contacts be sufficient to deal with the short circuit current, but the contact area of the arcing contacts themselves must also be capable of dealing with the current in the arc. We know quite well that an arc can only be maintained by supplying to the electrodes sufficient heat to keep them at incandescence.

We can imagine this heat as penetrating for a short distance below the face of the arcing contact, and this depth, multiplied by the contact area, would represent approximately that portion which becomes volatilised by the arc.

Clearly, then, according to this reasoning, the greater the contact area the less will be the depth of penetration, and the longer will the arcing contacts give service before requiring renewal.

Heating of Closing and Trip Coils.

Closing coils and trip coils for use with oil circuit breakers are usually proportioned so that the temperature rise cannot exceed 50 deg. C. in 30 seconds.

The effect of radiation is, of course, neglected, and the total watt loss is considered as being consumed in heating up the copper.

The heat loss produced in the coil in 30 seconds is clearly

$$30I^2R \text{ watt-seconds.}$$

Also if

s = specific heat of copper = 0·095 cal. per grm.
θ = temperature rise = 50 deg. C.
M = mass of copper in grms;

then, since 4·2 calories per second = one watt per second, we can write

$$30I^2R = 4{\cdot}2sM\theta$$

Now one lb. = 453·6 grms

Therefore $I^2R = \frac{4{\cdot}2 \times 0{\cdot}095 \times 453{\cdot}6 \times 50}{30}$

Whence $I^2R = 302$ W. per lb. of copper.

Conditions Existing during the Arcing Period.

The interruption of a flow of current is analogous to the introduction into the circuit of a resistance rapidly increasing in value to infinity. In the case of an oil circuit breaker, a thin film of oil is interposed directly in the path of the current at the instant at which the arc tips separate. Such a small quantity of oil must necessarily have a high ohmic value and an extremely low thermal capacity ; consequently, the passage of even a small current in the form of a spark is at this instant sufficient to produce a high temperature in the immediate region of the arc tips, and the original thin film of oil becomes dissociated by the heat into a bubble of ionised gas. A condition is then established which is favourable to the formation of an arc, and this condition will remain so long as a certain relationship is maintained between the voltage and gap length. The intensity of the spark following the interruption must be due primarily to the self-inductance of the circuit, and therefore the initial arcing conditions are to a certain extent independent of the particular values of voltage and current when separation occurs. The E.M.F. of self-inductance is in quadrature with the current, and even when separation takes place at zero current, the gap length can never, with a finite switching speed, increase with sufficient rapidity to prevent the E.M.F. of self-inductance puncturing the oil film and initiating a spark.

When the breaker is operating on normal load it is quite reasonable to regard the line voltage as assisting under certain circumstances in establishing the arc at the moment of interruption ; but obviously under short circuit conditions, when the voltage is practically zero, the creation of the arc must be due to the E.M.F. of self-inductance.

(To be continued.)

* The writer is indebted to Mr. S. Neville, B.Sc., A.M.I.E.E., for the mathematical investigation of this problem.

Indian Trade in 1921-22.

H.M. Senior Trade Commissioner in India, in forwarding to the Department of Overseas Trade the March number of the monthly trade returns of the Government of India, states that the total imports of merchandise into India declined from 335·5 crores in 1920–21 to 206·4 crores in the year under review. Imports from the United Kingdom fell from 204·5 to 150·9 crores (26 per cent.), while those of the United States fell from 35·3 to 21·6 crores (39 per cent.), and those from Japan from 26·4 to 13·5 crores (50 per cent.). The most noteworthy feature was the increase in the imports from Germany from 4·75 to 7·24 crores, the increases being mainly in dyestuffs, hardware, glassware, iron and steel.

Machinery Imports.

The most remarkable feature of the year was the prodigious import of machinery and millwork equipment. In 1920–21, the total was 22·37 crores, but in the past year this increased to 34·25 crores, of which the United Kingdom supplied 28·32 crores and the United States 4·51 crores. British shipments increased during the year by almost 11 crores, and American supplies by ½ crore. The principal increases were under the following heads: Cotton machinery (from 3·67 to 7·64 crores), jute machinery (2·77 to 4·32 crores), electrical machinery (2·19 to 3·90 crores), and boilers (1·59 to 2·55 crores). There were also substantial increases in machinery for mining, oil crushing and refining, paper, rice and flour mills. The only serious competition in machinery at present is that from the United States, but the United Kingdom more than maintained its position. An increase in imports from Germany (from 17 to 55 lakhs) was largely due to rice mill machinery and sugar plant.

The total imports expanded from 14 to nearly 19 crores, of which the United Kingdom supplied 18·4 crores. In this enormous trade there is as yet little competition, the imports from America being only 13 lakhs. Imports from Australia (mainly sleepers) rose from 12·4 to 20·5 lakhs, while those from Canada fell from 20·75 to 2·14 lakhs. The expansion in this valuable trade may be expected to continue in view of the new capital expenditure programme on railways, which amounts to 30 crores per annum for five years.

The trade in iron and steel products showed a considerable reduction, but German and Belgian wire nails, steel bars and channels, etc., showed increases.

Electrical Instruments and Apparatus.

This trade has been well maintained, the total imports in 1920–21 being 4·18 crores, compared with 4·06 crores in the past year. Supplies from the United Kingdom show little alteration, and are roughly 70 per cent. of the total (2·84 crores). American shipments were, however, reduced from 95 to 80 lakhs, while those from Italy rose from 7½ to 16½ lakhs.

Recent Developments in Power Production.*

By D. L. SELBY-BIGGE.

The Paper is a summary of the advances that have been made in the economics of power production during the past eleven years. The need for remodelling steam-raising plants is pointed out, the tendencies in steam-raising methods are noted, and the advances that have been made in turbine and condenser design are detailed. Finally a typical colliery power station is described. The author thinks much remains to be done before the bedrock of economy in power production is reached.

Eleven years have passed since the author read his last paper before the Iron and Steel Institute. Abnormal trade conditions now prevail, and various developments have taken place in power production which tend to greater economy. The main source of power in this country is primarily derived from coal. This is the datum line from which we must start in the investigation of the problems of power production. Immense quantities of combustible fuel of low-grade quality and waste gases, which with modern appliances and treatment can be economically converted into steam or other assets of great value, still remain unutilised.

The Economic Problem.

Of late, however, the economics of power production have been more closely studied. Present methods in the generation and transmission of electric power have reached such a high standard that we can only expect small economies in the engine-room or power station. We must turn to the boiler-houses and the efficient use of various grades of fuel for further savings. Here an immense field for economy exists. Consideration will also be given to the utilisation of waste assets—*e.g.* blast-furnace gas, coke-oven gas, and gas from reheating and regenerative furnaces, for steam-raising for power production purposes. One very important point is the need for skilled supervision and control in the boiler-house. In most collieries and works the boiler staff employed is not of such a high standard as the staffs usually employed in the engine-room. Possibly collieries and iron and steel works have hitherto not required to work on such fine margins as a corporation or public supplies, and have therefore used coal and waste-heat in a prodigal manner.

In collieries advances in washing and grading fuels, and in the installation of coking and by-product plants, have reduced the amount of fuel usually allocated to boilers, and have increased the quantity of low-grade fuel, which will not bear the cost of transport and for which in normal times there is not a ready sale. In iron and steel works the introduction of the more efficient turbo-blower has liberated large quantities of waste gas, which is now available for power production.

Much has been heard during the last few years of the urgent necessity for an abundant supply of cheap power. The right source from which to obtain such power is from the coal at the collieries, and the waste gases at iron and steel works.

Coal Consumption.

There is a wide field for the remodelling of steam plants at collieries, which consume about 18 000 000 tons per annum, or over 7 per cent. of the total coal raised.

In twenty-four collieries studied by the Board of Trade Coal Mines Department in 1918, the consumption of coal varied from 4·5 to 16·5 per cent. of the total production. In certain districts—notably South Wales—much attention is being paid to coal economy, but there are still many cases where little is being done. Interest attaches to the possibility of utilising "pit heaps," many of which have been standing for forty or fifty years. Mr. David Wilson gave, in 1918, a comprehensive analysis of these fuels.

It was calculated that there were some three million tons of refuse coal lying at the pit heads, of an average estimated calorific value of 5 000 B.Th.U.'s.

The author reproduces a table from the paper specified to illustrate the great variety of such waste-heaps. Thus calorific values varying from 3 825 to 10 240 B.Th.U.'s are recorded; the ash percentage varies from 10·51 to 67·65, the moisture content from 1·75 to 27·39. It was proved that a great deal of this material could be used for steam-raising.

For the iron and steel industry the estimated consumption for 1913—the last available normal year—was 31 000 000 tons (including coal used for smelting and blast-furnaces as well as steam-raising). It appears the consumption of coal under boilers in the iron and steel industry is approximately 5 500 000 tons per annum.

In the report issued by the Electricity Commissioners in January of this year the number of stations is given as 403, the total units generated as 4 965 514 403, the average coal consumed 3·32 lb. per unit generated, the lowest coal consumption 1·7 lb. per unit, and the highest thermal efficiency recorded 17·75 per cent.

The Cleaning of Coal.

The Froth flotation processes for cleaning fine coals deserve mention. Coal or coal-bearing waste crushed to pass a screen of about 1-10 in. linear aperture is treated as a pulp consisting of approximately four parts of water to one part of coal. There is a series of units each composed of an agitation box and a frothing box. The pulp is initially mixed with about 1 lb. per ton of coal of a suitable oil reagent; minute air bubbles are then formed and become attached to the coal particles. The pulp then passes from the agitation box to the first frothing box, where it is brought to comparative rest, the air-buoyed coal being permitted to rise to the surface and form a froth, which is automatically skimmed from the surface and contains approximately one part of water to one part of dry coal, and, as it is free from clay or shale slime, filters with readiness. Continuously operating filters can deal with over 2 000 lbs. of dry coal per sq. ft. of surface per 24 hours on this material, delivering a product containing 12 to 14 per cent. of moisture.

Recoveries of 98·9 per cent. and over are recorded. Several units having capacities of 40 tons hourly are now in course of erection, and with an average cost of coal-cleaning (inclusive of power and labour, but exclusive of interest and depreciation) of 4d. per ton treated. The potentialities of these processes are therefore considerable.

Steam Production.

The author then refers to several main tendencies in steam production, leading to advances in efficiency. Water-tube boilers capable of evaporating normally 130 000 lb. per hour have been absorbed; in the Ladd boilers at the Detroit works of the Ford Motor Company 276 000 lbs. of water per hour for fifteen hours, and 327 000 lb. per hour for one hour, were actually evaporated from one of these boilers. There appears no limit to the size of boilers, but with industrial plants 30 000 lb. capacity is a convenient size.

Pressures of 250 lb. are now common and several boilers work at 350 lb. One large new boiler-house is being even operated at 475 lb. per sq. in. Higher pressures seem feasible if desired. Integral superheaters to give a final steam temperature of 650-750° F. are available. This maximum is unlikely to be exceeded, as it approaches the limiting temperature of steel tubes.

The stokers employed are now largely mechanical, and include the chain grate type with natural and forced draught, sprinkler and coking stokers and multiple retort types. These varieties are described and illustrated in the original paper. Among the advantages claimed for the underfeed stoker are (1) greater economy and boiler efficiency with a given coal; (2) ability to burn a wider variety of fuels; (3) ability to meet sudden demands for steam, and other constructional advantages such as less space occupied in front of boilers, examination and repair of stokers without removal, no necessity for high chimneys, self-dumping clinker plates, etc. The chief feature of the multiple retort stoker is that no refractory brickwork setting is needed. Such a stoker can be assembled from any number of retort units, without limit to size and capacity of furnace The type is specially useful for modern large unit boilers. The development of these stokers has been very interesting, a feature being the continuous automatic slicing of the fire-bed whereby incombustible residues are reduced to a minimum. Maximum thermal efficiency is attainable both with good and very bad coals. A brief account is also given of the well-known Bennis sprinkler with compressed air furnace, with which very poor coal, containing up to 53 per cent. of incombustible material, can be used.

Production of Power from Waste Gases.

(A) *Blast-furnace Gases.*—In general, blast-furnace gases in this country are uncleaned. When using such gas for firing boilers an external chamber is provided. This does not give such a good intermixture of air and gas as a Bunsen type burner, but has the advantage of not becoming clogged up with

* Abstract of a paper read before the Iron and Steel Institute.

dust. With the advent in iron and steel works of gas-cleaning apparatus, the tendency is now to fit boilers with Bunsen or multiple-type burners. With clean gas and burners the efficiency can be raised and 73 to 75 per cent. (as compared with 63 to 65 per cent.) obtained, so that for each lb. of actual steam evaporated about 16 cub. ft. of gas at 100 B.Th.U.'s per cub. ft. is required.

In a test using blast-furnace gas in conjunction with a Harrison furnace, the water evaporated per hour from and at 212° F. was 12 495 lb.

(B) *Coke-Oven Gases.*—There is a wide field for the use of surplus heat from coke-ovens and by-product coke-oven plant. As an average 80 per cent. of the gas will be available in the form of waste heat at a temperature of 1 800° to 2 000° F., and 20 per cent. in the form of surplus live gas with a calorific value of 450 to 500 B.Th.U.'s.

By using waste heat and surplus live gas 1¼ tons of water can be evaporated from and at 212° F. per ton of coal carbonised. This gas is generally burnt in Bunsen burners. Efficiencies for the boiler and economiser combined as high as 80 per cent. have been obtained. Under normal working conditions, an efficiency of 70 per cent. can be relied upon for the boiler alone.

(C) Great scope for the use of waste heat from reheating puddling and other furnaces, where burned gases are available at 1 800 to 2 000° F., also exists. With a well-designed boiler 5½ to 6 lb. of water can be evaporated per lb. of coal burnt.

One firm installed a water-tube boiler for utilising the waste heat from two hoop-mill furnaces consuming about 10 cwt. of coal per hour, and was able to save approximately 42 tons of coal per week.

(D) *Gases from Regenerative Furnaces.*—In furnaces of this type, with gases available at 1 000° to 1 150° F., the draught requirements are generally about 1 in. W.G. This difficulty is overcome by installing a boiler combined with an induced draught fan.

As a general rule, the coal consumption at the producers is 5½ to 6 cwts. per ton of steel produced. An average evaporation of about 2 000 to 2 200 lbs. from and at 212° F. can be obtained per ton of steel with gases entering at 1 100° F.

Waste-Heat Boilers.

Kirke Waste-Heat Boiler.—This boiler consists of a drum traversed by straight tubes of abnormal length relative to their bore, through which hot products of combustion already burnt in some other furnace are drawn at a high mean velocity not less than 40 ft. per sec., by means of an induced draught fan or other mechanical means.

In the front of the boiler a superheater may be arranged, over which the products of combustion pass before entering the boiler tubes. An economiser is not absolutely necessary, but the heat available for transference to the water therein is so much reduced that the whole of the water heated in the economiser can be usefully used in the boiler instead of only a portion of it.

This type of boiler claiming tube efficiencies of 90 per cent. or over, minimum radiation losses and exceptional cleaning facilities, justifies its use with even very low grade heat.

Thus, in a case mentioned, an evaporation of 2 300 lbs. from and at 212° F. per hour was obtained. This boiler is suitable for generating steam from blast-furnace gas which, owing to its poverty, produces products of combustion at a moderate temperature (say 1 000° C. only).

A brief description of the Kirke gas-fired boiler, which is generally similar to the above, is also given. It is mentioned that a boiler 7 ft. diameter, working on producer gas, with 2 in. draught, can evaporate 12 000 lbs. of steam per hour.

Pulverised Fuel.

The idea of pulverised fuel is not new. In 1831 an English patent was issued to Mr. J. S. Daws, and this was rapidly followed by a number of patents in England, the United States, and on the Continent.

There are not many applications of the system in this country, and more attention has been given to the subject in the United States and on the Continent. Two years ago, in the United States 11 000 000 tons of coal were used per annum in powdered form. The amount is now much increased. In France progress has also been rapid. Installations were only commenced in 1918, and there are now more than 200 turbo-pulverisers alone in successful operation.

The pulverised coal system for steam generation at the plant of the Puget Sound Power and Light Company consists of ten boilers, with a total heating surface of 41 000 sq. ft., together with complete drying and pulverising plant. The combustion volumes of the furnaces per square foot of heating surface were 0·2 cub. ft. under four 3 000 sq. ft. boilers and three 4 000 sq. ft. boilers; 0·3 cub. ft. under one 5 000 sq. ft. boiler and one 6 000 sq. ft. boiler; and 0·45 cub. ft. under one 6 000 sq. ft. boiler. The coal used is refuse material accumulated during the last twenty years, and is very fine, practically all of it passing through a 20-mesh screen. The heating value averaged 9 300 B.Th.U.'s. About 190 000 tons of this coal have been burned with an average boiler efficiency of 80 per cent., and very high evaporation was obtained. Altogether the results appear to be remarkable.

Other instances in America are the powdered coal installation at the boiler plant of the Missouri, Kansas, and Texas Railway at Parsons, Kan.; the new Lakeside Generating Station of the Milwaukee Electric Railway and Light Company, and at the comparatively new River Rouge Boiler Plant of the Ford Motor Car Works at Detroit.

At the Ford installation the boilers, which are without economisers, and are four in number, have each 26 400 sq. ft. of heating surface. It is said that 276 000 lbs. of water per hour were evaporated from one of these boilers for fifteen hours, and for two hours 327 000 lbs. of water from one boiler per hour. These boilers are probably the largest boilers ever installed. At the maximum the evaporation was just under 12½ lbs. of water per square foot of heating surface. Favourable experience of powdered fuel installations on the Continent is also quoted, and a brief account is given of the use of powdered fuel in reheating processes.

Steam Turbine Progress.

Recent improvements in steam comprise the use of higher steam pressures and higher superheat, and the adoption of higher turbine speeds.

Mixed pressure turbines have played a prominent part in connection with steam-driven winders and rolling-mills utilising the exhaust steam. However, the centralisation of power production in collieries and steelworks and the electrification of the entire plant tends to lessen the field of application of the mixed pressure turbine.

Figures are given for pressure, temperature, &c., steam consumption, &c., of various types of turbines. Thus, with some Metropolitan-Vickers (Rateau) types values ranging from 12·6 to 16·8 lbs. per kWh are recorded, with Parsons high-pressure type consumptions from 13·5 to 14·92 lbs. per kWh.

Reducing turbines have recently been preferred. This machine is arranged automatically to bleed steam at a certain pressure for process work, mainly in paper mills, oil factories, distilleries, &c., or for heating purposes. When large quantities of low-pressure steam are required—*e.g.* in paper-mills, the saving is considerable.

Turbo-compressors find an extensive application where compressed air in pneumatic tools for mining operations, for coal cutting, for riveting in shipyards, &c., is needed. One of the largest compressors built in this country has a normal capacity of 30 000 cub. ft. of air per minute, compressing this quantity against 100 lbs. per sq. in. G.

Turbo-blowers are machines working against moderate air pressures, up to 40 lbs. per sq. in. The 35 000 cu. ft. is a common size, but upper limits are determined solely by economic considerations.

Condensers.

With reciprocating engines little can be gained in steam economy by the installation of condensers to give more than 26 in. Hg. vacuum with the barometer at 30 in. This does not apply to steam turbines with which the highest obtainable vacuum can be fully utilised.

Available types of condensers include: (1) Surface condensers; (2) Jet condensers with water extraction pumps and separate air pumps or other air extraction appliances; (3) Ejector condensers with water-circulating pumps and no separate air pumps.

With surface condensers condensed steam can be used for the boilers, but the first cost is high, and their use, where clean condensing water cannot be obtained, necessitates troublesome and costly cleaning of tubes and periodical renewal. The modern method of dealing with boiler feed water by heat and soda ash has extended the application of condensers of the jet or ejector types.

Industrial sites are only rarely near a natural and adequate supply of water for condensing. However, with a loss by evaporation of about 80 per cent. of the boiler feed, the condensing water can be re-used after cooling in towers or by spraying over ponds.

For high vacuum plants with artificial cooling the ratio of condensing water to steam condensed should not be less than 60 : 1. This gives a maximum requirement of temperature reduction of 10° F. for the cooling installations.

The area required for cooling towers is 0·8 to 1 sq. ft., and for spray cooling plants 4 to 5 sq. ft. per kW of plant installed. Where space is available, spray cooling is preferable to tower cooling, as the first cost is lower and better cooling is obtained with sprays. Moreover, maintenance charges are negligible, whereas with cooling towers maintenance and depreciation may involve a heavy charge.

Example of a Typical Industrial Power Station.

It is of interest to describe a typical industrial power station, *viz.*, the actual case of a colliery power station in this country.

This station supplies a group of collieries principally for underground power (pumping, hauling, coal cutting, and general purposes, and also for main shaft winding). The system of supply settled in 1907 was 3 000 V 3 phase, 50 cycles.

The station equipment now comprises one 1 500 kW and two 3 000 kW turbo-alternators. The condensing plant is of the multi-jet type, all the water for condenser purposes is re-cooled through spray nozzles. A vacuum of 28 in. under full load conditions on the large units (with bar. at 30 in.) is maintained. There are six large boilers of the water-tube type, each capable of evaporating 22 000 to 27 000 lbs. of steam per hour. The steam pressure is 200 lbs. per sq. in., with superheat to 588° F. The condenser equipments are all joined together; any of the three circulating pump equipments will operate any condenser.

No. 1 condenser is operated by a steam-engine, the other two by motors. There is also a steam-driven exciter and a motor-driven exciter, the latter of full capacity for all the units in the station. The exhaust steam from the condenser and exciter engines, feed pumps, and fan engines is used for heating up the feed water, which is treated in a heater softener by the temperature and soda ash method.

The Erith stokers are each of the seven retort type and are capable of burning approximately 4 340 lbs. of low-grade fuel per hour. The first four are operated by electric motors, the fifth and sixth are operated by steam. Hydraulic wagon coal-tippers are used. Each boiler is fitted with an independent elevator and all elevators are separately driven.

The fuel was charged at approximately 11s. 7d. per ton. With low-grade fuel charged, as is possible in many cases, at 5s. per ton at the colliery, the fuel cost would be reduced to 0·077d. per unit, and the cost of production would then become 0·13d. per unit.

Gas Engines.

Single installations of from 15 000 to 20 000 H.P. of gas engines working upon blast-furnace gas are already in operation in this country.

In a modern furnace producing 1 million cub. ft. of gas per hour, only 0·55 of this is required for the furnace, leaving 0·45 million or 450 000 cub. ft. of gas available per furnace for other purposes. This at 150 cub. ft. per kWh is equal to about 3 000 units per furnace per hour. With fifty furnaces the aggregate would be 150 000 units per hour and 1 030 510 000 per annum; this with the boiler saving represents an economy of about 400 000 tons of coal per annum.

Results are presented for a 1 500 H.P. gas engine, the B.Th.U.'s per B.H.P.-hour being 10 400 in the first half-hour and 9 650 in the third half-hour's working. Particulars are also given of a 450 H.P. engine using coke-oven gas at a colliery a thermal efficiency of 28 per cent. on overload and 24·4 per cent. on half load being attained. In the former case 9 100 B.Th.U's per B.H.P. was consumed.

Oil Engines.

Some particulars for internal combustion engines working on oil are given. Thus, in a test on Sultzer-Diesel engines of 2 000 B.H.P. the total running cost of 0·384d. per B.H.P. hour.

Other cases are mentioned where cost per kWh worked out to 0·745d. and 0·810d. respectively.

Conclusion.

Much remains to be done before the bedrock of economy in power production is reached. Water power and tidal power have not been discussed in this paper. Coal, however, remains the basic source from which we derive the bulk of the power in this country.

Attention may with advantage be directed towards the following points :—

1. The cleaning of fuel from ash and other impurities prior to combustion.
2. The reduction of labour, and economical burning of fuel :
   (*a*) by the use of efficient mechanical stokers ;
   (*b*) by fuel in powdered form.
3. The purification, softening, and heating of boiler feed-water and provision of efficient cooling plant for condensing purposes.
4. A closer and more scientific control in the boiler-house.
5. A more comprehensive utilisation of waste gases from blast-furnaces, coke-ovens, and producers.
6. The development of markets, either industrial or public supply, to absorb the surplus power available from collieries and iron and steel works.

Reviews.

Rays of Positive Electricity and their Application to Chemical Analyses. By Sir J. J. THOMSON, O.M., F.R.S. (London : Longmans, Green & Co.). Second Edition. 16s. net.

This is a well-known work devoted mainly to a new method of determining atomic weights by the simultaneous electrostatic and magnetic deflection of positively charged atoms. Since the magnetic deflection is inversely proportional to mv, and the electrostatic deflection is inversely proportional to mv^2, where m is the atomic weight and v the velocity of the atom, the simultaneous deflection allows us to determine both m and v. If both deflections are recorded on a screen normal to the original direction of the atomic "rays," a gradual increase in the velocity of projection will trace out a parabola on the screen, which is then measured for the purpose of the above determinations.

The present second edition of the book is about double the size of the first edition, which was published in 1913. It contains many new chapters, notably on the use of hot cathodes covered in the lime, and on Aston's focus method, by which particles of the same e/m but different velocities are made to converge towards the same point. There is also an account of the Doppler effect in positive rays and of the polarisation of the light from them, both discovered by Stark. The author discusses the origin of the mysterious parabola indicating an atomic weight 3, and guardedly refers to Fabry's discovery of a line in the spectrum of certain nebulæ, which also indicates that atomic weight.

The value of the new method of chemical analysis lies chiefly in that it is not affected by impurities. It has already led to the discovery of two forms of chlorine, of atomic weights 35 and 37 respectively, and has brought the atomic weights closer to integral numbers than ever before.

E. E. FOURNIER.

Practical Testing of Electrical Machines. By L. OULTON and N. J. WILSON. (London : Sir Isaac Pitman & Sons, Ltd.) Pp. iii+158. 6s. net.

This is a useful book on the testing of electrical machines and transformers, which should be of value to the college student or apprentice, as well as to the engineer actually engaged on a works test plate, or in working up tests in a design office. A full description is given of the tests which are usually employed commercially to determine the satisfactory operation of any machine, both from the standpoint of design and manufacture. Numerical examples are included, which are worked up into curves, thus explaining the uses to which test figures are put, and indicating the information to be obtained from them. It is regrettable that in revising the book for this, the second, edition, the symbols have not been brought into line with the recommendations of the International Electro-technical Commission.

A useful appendix is formed by the inclusion of the principal rules of the B.E.S.A. for the standardisation of electrical machinery.

L. H. A. CARR.

The C. M. and M.-Delas Air Extractor.

Interesting Test Taken in Paris.

A short while ago we gave an account of a new air extractor which had been designed for use with condensing plant, and we are now able to give details of some tests on this equipment which were carried out in the Paris workshops of the Société Condenseurs Delas, by whom the apparatus is made. The tests were carried out with an air pump made for a large turbo set to substantiate the claims with regard to steam consumption made by COLE, MARCHENT and MORLEY, who are licensees for the manufacture of these condensers in this country, and who had put them forward in connection with an extension scheme at a Corporation Power Station. The air pump makers made satisfactory arrangements to reproduce working conditions. These consisted of complete means for loading the air pump, both with air and vapour in any desired proportions, and for regulating a supply of water at any desired temperature to an intermediate condenser, and thereafter extracting it.

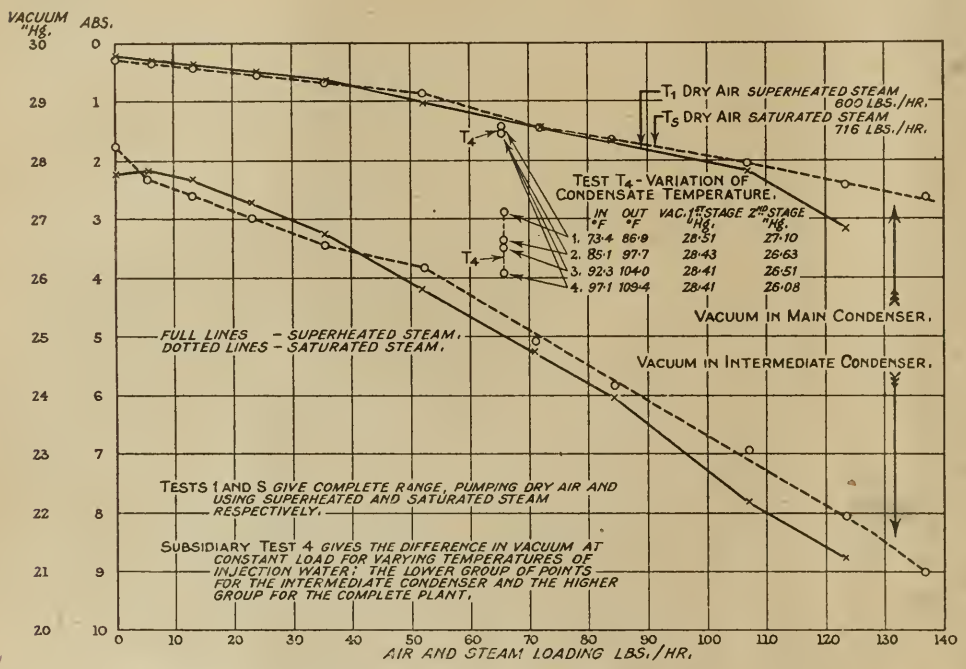

FIG. 1.—CURVES GIVING RESULTS OF TESTS ON DELAS EXTRACTOR

The Air Pump.

The air pump in question is one in which the air and vapour to be extracted from the condenser is compressed in two stages. Each of these stages is operated by a single steam jet and diffuser. The steam used by the first jet is condensed by a portion of the condensate used as the condensing water of a small jet condenser. The special features of the pump are that the diffuser is of the parallel type in each case, and is completely water-jacketted. It is claimed that this construction does away with the instability observed in other makes of pump when used for very high vacuum with very little loading. It is stated that the water-jacket to the diffuser is a necessary feature in connection with the use of a parallel diffuser, the tendency of the combined stream of " working steam " and " gases pumped " to diverge being counteracted by the rapid condensation caused by the water-jacketted diffuser.

Details of the Tests.

The pump was tested for the full range of the experimental apparatus when pumping dry air, and also when using for its working steam superheated and saturated steam alternatively. A series of supplementary tests were taken in which to the dry air were added definite quantities of saturated steam, all the results being tabulated in the following tables and plotted in the curves which are given herewith.

It will be noted (from the curves Fig. 1) that the pump does not give the same vacuum weight for weight when part of the duty is steam. This is obviously because the steam has a much greater volume than the equivalent weight of air and the pump has, to some extent, a " volume " characteristic as well as a " weight " characteristic. The difference is not very serious.

We understand the pump showed an extraordinary stability over all working ranges explored, and no change was made in the apparatus or adjustments in changing from superheated to saturated steam.

It will be noted from the curves and tables that the steam load was entirely condensed in the intermediate condenser, since the second stage compression was just the same when steam load was added to the air load as when air load alone was dealt with.

A further subsidiary test was made in which the load of air and steam was kept constant. The temperature of the injection water was varied by heating it up with steam previously to its use. The vacuum in the intercondenser naturally followed this injection temperature, but the net result was that the first stage took up almost all the work that the second stage was compelled to drop. This shows that the pump is not particularly sensitive to condensate temperature, and can therefore work at a high efficiency when connected to the actual condenser.

Limit of Load Obtainable.

The limit of the load obtainable with the experimental apparatus can be seen by reference to the diagram of the experimental apparatus (Fig. 3). In this diagram it will be noted that an artificial " U " or water seal had to be provided to imitate working conditions. When the pressure in the intermediate condenser was greater than the vacuum in the hypothetical condenser A, then, of course, the water on the right-hand side of the limb was depressed. As the pressure in the intermediate condenser increased, it is naturally seen in the limit that the water seal would be blown. With a greater water seal, of course, the range of the pump could have been taken further, but this would have served no useful purpose as being outside the working range of the pump.

When considering the above report and results of tests allowance should be made for the condensation of the steam which passes through the nozzle to extract a mixture of air and steam. As is well known, this is very detrimental to the results.

Again, the vacuum in the intermediate condenser remains approximately the same for any variation in temperature of between 86·9° F. and 109·4° F., and it should be remembered that in practice the condenser temperature never varies between such limits, otherwise the vacuum in the main condenser would drop because the temperature of the circulating water would be too high for the same vacuum to be obtained as with circulating water at a lower temperature. Therefore too much steam is used by the nozzles of the first stage without gain in vacuum. A vacuum of 28·5 in. is never required with the condensate at a temperature of 97·1° F.

After taking the above into account it has been found that in practice nearly half the steam used by the first jet could be saved.

Working Conditions.

As mentioned above, the experimental apparatus only admitted of a limited range for the test. The reporter, therefore, arranged to inspect a pump actually working and was enabled to do this by a visit to Billancourt Station, where a Delas pump was seen maintaining an excellent vacuum on a 6 000 kW set. A photograph of this pump *in situ* (Fig. 2) is given herewith. The pump exhausted the condenser to a vacuum of 25·3 in. eighteen minutes from the start,

using the second stage of the pump only, and completed the exhaustion to 29·5 in. on adding the first stage after a further three minutes' operation.

The actual steam consumption of the extractors at this station was approximately 500 lb. of steam per hour for a vacuum of 28¾ in., but the jets had been designed according

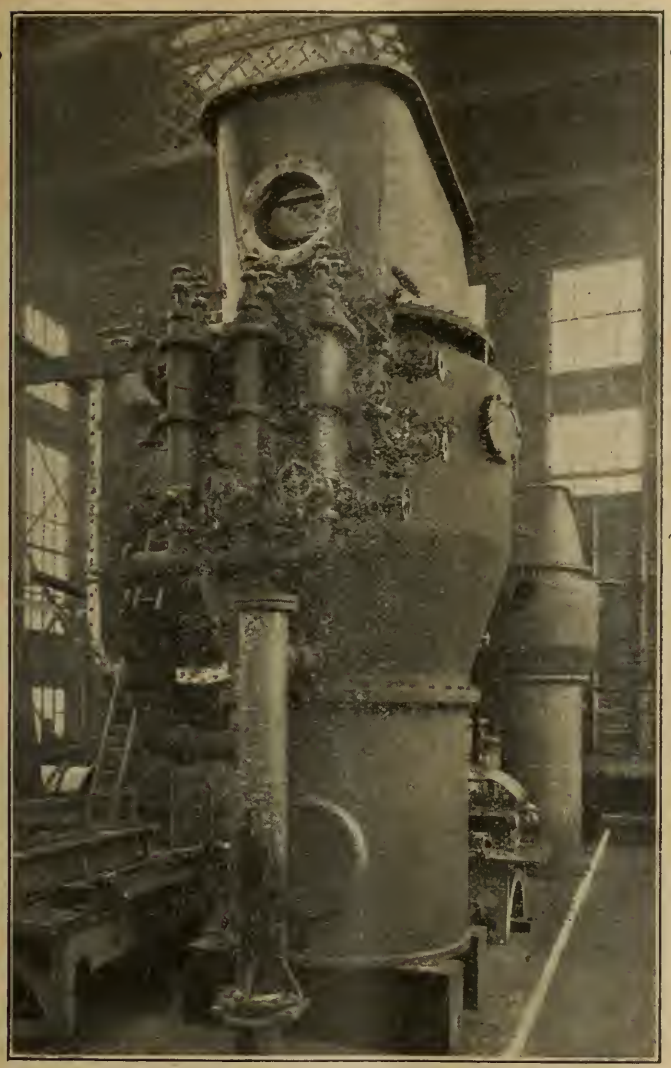

FIG. 2.—C. M. & M. JET CONDENSER, HAVING A CAPACITY SUFFICIENT TO DEAL WITH 82 000 LB. OF STEAM PER HOUR, FITTED WITH THREE SETS OF C. M. & M.-DELAS STEAM JET AIR EXTRACTORS OF THE INTERMEDIATE CONDENSER TYPE.

to the French method—*i.e.*, for securing the best results when extracting dry air. When dealing with saturated air the first jet is, of course, too large in diameter; and if designed according to English practice for dealing with saturated air, the steam consumption would be very considerably reduced, as only about half the amount would be required for the first jet.

In support of the statements made by Cole, Marchent and Morley, Ltd., as to steam consumption, which was the primary object of the inquiry, it was found that, on comparing results of the C. M. & M.-Delas air extractor with other first-class makes of a similar type, the reporter was able to give the following comparative results :

Vacuum maintained inches.	Steam used by the C. M. & M.-Delas Pump per cent. less.
28·25	24·9
28·5	19·0
28·75	22·4
29·0	20·0

As a result of the test it was considered that the claim made by the firm that this pump is an improvement on existing equipment was substantiated by the tests made, and the

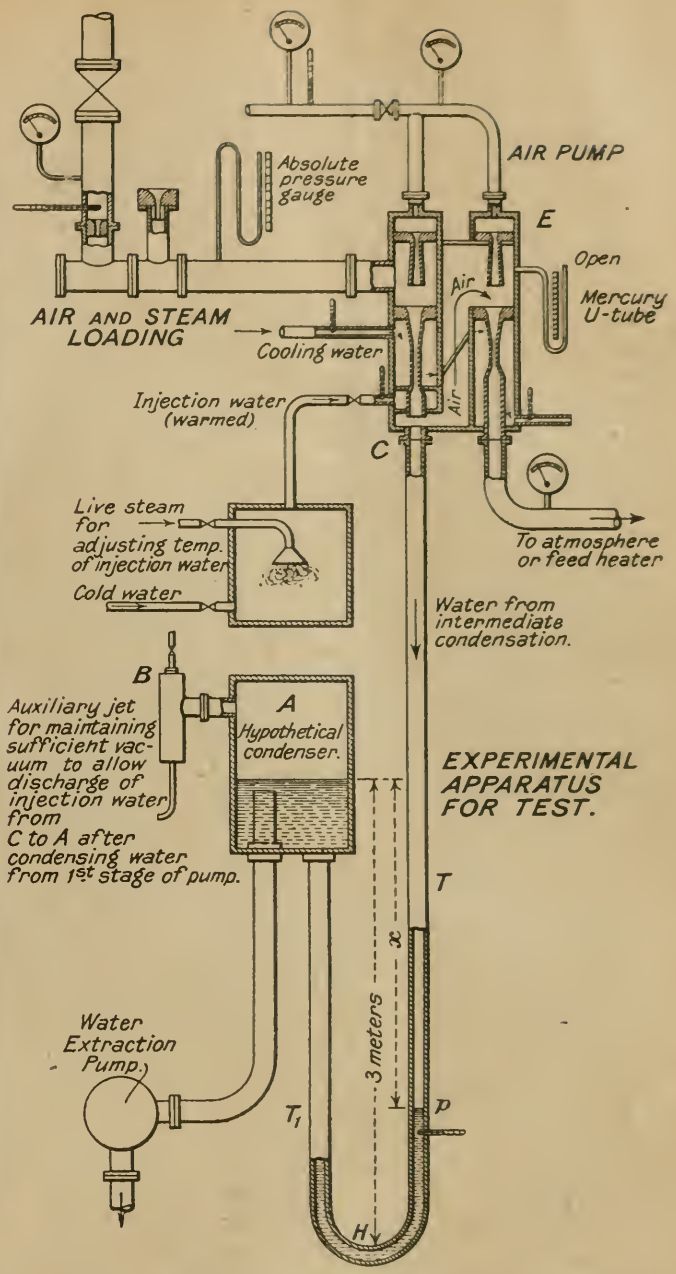

FIG. 3.—DIAGRAM OF THE EXPERIMENTAL APPARATUS USED FOR THE TESTS.

C. M. & M.-Delas pump was recommended for the plant for which the test was carried out.

The Problems of Technical Education.

At the annual conference of the ASSOCIATION OF TEACHERS IN TECHNICAL INSTITUTIONS, held last week in London, the necessity for the immediate appointment of a special committee of inquiry to investigate the whole field of technical education in its relation to education generally and to industry was urged. In his presidential address Mr. J. PALEY YORKE pointed out that it was now forty years since any national inquiry on technical education had been made, and that the advance of scientific knowledge and the development of the applications of science to industry and manufacture since that time had been tremendous. Technical education had developed too, but it had developed furtively and unobtrusively; and it had developed beyond the recognition of many of those who were supposed to be its guardians. The conference urged that some qualified committee should advise whether or not technical education should be promoted, and, if so, to advise what measures were necessary for that promotion in the interests of those industries and professions which depend upon the applications of science.

Lord Burnham's Opinion.

Lord BURNHAM expressed the opinion that technical education was slowly gaining its proper place in the assessment of national values. In reality it was only thirty years old, and it had not proceeded from motives of State policy in this country as it had in Germany, nor had it been created by the wands of multi-millionaires as in the United States. It had not come from the urgent demands of the great industries, and comparatively little had been done for its foundation either by employers or employed. Lord BURNHAM thought, however, that employers were showing a livelier sympathy with technical training, though he noted that the Trades Union Congress agenda paper contained small reference to it.

Real Scientific Education.

The PRESIDENT also urged that technical education, which is definitely scientific education, was as essential educationally and culturally as any other brand of intellectual activity. He said that the time had come when reconsideration should be given to the essentials of "a good general education," and whilst he would not urge for too early specialisation, yet submitted that the sum total of knowledge was so great that it was inevitable that each individual should be a smatterer in most things and something of a specialist in one. He asked for careful investigation of the old idea that any subject which approaches the region of usefulness could not possibly be of any educational value. Sir William Noble had said that those would have the best chance and hold the field who had 70 per cent. of specialised knowledge and 30 per cent. of the habit of dealing with men. Lord BURNHAM did not think that education should exist in water-tight compartments such as that which prohibited the teaching of modern languages in junior technical schools, and, having regard to the world-wide problem, he would say to technical teachers that they could not make their field too wide, provided that it was in accord with and in subordination to the first principles upon which they had drawn.

Need for Research Facilities.

Attention was also drawn to the fact that the opportunity for research work in technical institutions was scant, and that it was essential that teachers of technology should have both the opportunity for research and for contact with industry. The difficulties and the possibilities of abuse were recognised, but the mutual advantage which would accrue both to education and to industry was so great that it was suggested some scheme might be devised whereby industrial directors could submit problems to the education authorities and through them to the technical institutions in the area. It was recognised that, owing to a certain amount of necessary publicity, all research problems could not be dealt with that way, but much good work could be done.

No Reduction in Grants.

The proposals to reduce the grants for scientific research and national scholarships for higher education were criticised. It was pointed out that these reductions would imperil scientific and industrial development; and that the percentage reduction in the estimates for these items was greater than that for items in other branches of educational work.

Useful Co-operation.

Reference was also made to the scheme of examinations which had been inaugurated by the Institution of Mechanical Engineers in conjunction with the Board of Education. It was foreshadowed that other professional institutions would inaugurate similar schemes. Whilst the conference looked with considerable interest upon the scheme, which seemed to be full of promise, it was made clear that that interest would speedily evaporate if it developed merely into an examination.

Our Spoon-fed Traders.

By SIR ERNEST BENN.

Our business men are not rising to their opportunities. There never were so many opportunities in the world, and trade was never so slow. So far as I am able to diagnose the position this unfortunate situation arises from the habit of spoon-feeding into which trade and industry has sunk. For the purposes of war everything had to be arranged for everybody, military discipline had to be imposed upon us all, we were enjoined to obey and to submit our will and our opinion to higher authorities. We absorbed this habit so thoroughly that we have almost forgotten how to act upon our own initiative. If anything is wrong the only thing we seem capable of doing is to pass a resolution and send it to some Government department. If, as of course happens, we get no satisfaction in that way, we then content ourselves with pious reflections upon the plight of the foreigner or the follies of somebody else, and we fold our hands and wait for trade to revive. Could anything well be more silly?

Getting Back to Smiles.

As a nation of business men we need to get back to Samuel Smiles; we want a big dose of his old-fashioned self-help. If some of the great men whom Smiles catalogues for us could come back to life and compare present conditions with those with which they had to struggle they would be amazed at the apathy, the indifference, the helplessness, of the modern commercial mind. The working-man no longer thinks for himself, he does what his trade union leader tells him. His master is following in the same foolish way.

Now trade is what we make it and will never be anything else. The conditions of which we complain are very largely the result of our own actions. Politicians and Government departments can only deal with them after they have arisen.

Progress and Individual Effort.

It is not necessary to go back so far as dear old Samuel Smiles in order to illustrate these points. Such men as Westinghouse and Stokes in modern times have not relied upon trade associations, upon Government development departments, upon outside agencies or public opinion. They have invariably had all or most of these things against them. A study of progress shows that everything we enjoy has been forced upon us by individual effort on the part of someone who was strong enough to believe that his salvation rested in his own hands, and that he had a duty to perform quite independent of anybody's opinion. Other people cannot arrange our fortunes for us, nor can we arrange a fortune for other people. Our salvation is in every case in our own hands, and that salvation is spelt WORK.

A Contrast.

These truths are so evident to-day that it seems almost absurd to state them. We can see them demonstrated in individuals and in nations. In Russia we have one great and valuable illustration which ought to satisfy the world for all time of the futility of organisation, administration, and all those other fetishes which we call Bolshevism when we see them in the Russian form, but fail to describe them properly when we are ourselves practising the same vices in our own arrangements at home. In Germany we see the other side of the matter; the whole world is busy arranging affairs for Germany; every Government in Europe is telling Germany what it ought to do; supreme councils and world-wide conferences meet regularly in order to put Germany right. Germany the while goes on quietly working, and by that simple expedient will, in course of time, defeat the lot of us.

It is no good bothering what other people do or what other people think. From a business point of view this attitude of mind is fatal; the business man who talks of trade as bad, who tries to find in the faults of others excuses for his own failings, who is waiting until others make trade good, before he will himself become active, is no business man at all; he ought to join the most socialistic trade union he can find.

New G.P.O. Chief Engineer.

Major T. F. Purves, O.B.E., the new engineer-in-chief of the Post Office, was born at Blackadder Mount, Berwickshire, on December 31, 1871. He was educated at Greenlaw and at the Duns Academy. He entered the Post Office service by open competitive examination in 1889, and was appointed telegraphist at Edinburgh. He studied science at Heriot-Watt College and Edinburgh University, and in 1892 won the first medal of the Heriot-Watt College in electricity and technical telegraphy, as a result of which he was in that year selected for transfer to the engineering department in Edinburgh. In 1894 he secured, by departmental examination, an appointment as mechanical and electrical draughtsman in the Engineer-in-Chief's Office, London, and in 1900, after a further competitive examination, he was appointed Technical Officer on the Headquarters staff of the Engineer-in-Chief. In 1905 he became assistant superintending engineer for London, and the following year he was transferred to a similar position in the Southern District of England. In 1907 he returned to headquarters as staff engineer in charge of the designs section.

War Services.

On the outbreak of war he took a keen interest in the supply of electrical equipment to the Army Signal Services, in which many thousands of the P.O. engineering staff were engaged. To meet

Major T. F. Purves, the New Engineer-in-Chief of the Post Office.

modern trench warfare conditions he devised and sent out special adaptations of telegraph and telephone apparatus. As a result he took up a commission in the Royal Engineers as a liaison officer between the Army Signal Services and the Post Office. He also designed a series of new types of electrical signalling and detecting apparatus for military purposes, and controlled their manufacture and supply.

Assistant Engineer-in-Chief.

In June, 1919, Major Purves was appointed Assistant Engineer-in-Chief, in succession to Sir William Noble, whom he now succeeds, at the age of 50, in the premier position of Engineer-in-Chief. As the position of the Engineer-in-Chief is one of the most onerous in the country, involving the supervision of almost every type of electrical engineering plant, to the value of nearly one hundred millions sterling, the responsibility for an expenditure of about fifteen millions per annum on new construction and maintenance, and the control of a highly technical staff of about 25,000, this wide experience will be a great advantage.

Future Developments.

In the course of an interview with a representative of "The Times," Major Purves said he hoped to be Engineer-in-Chief for ten years, and in that time, if the country continued to prosper, the number of telephones in use should approach four millions. All overhead wires and aerial cables in our large towns would be cleared away. Exchange accommodation and line plant would overtake requirements, and in all parts of the country the service would be available at short notice to any subscriber. The underground trunk system of telephones and telegraphs would be extended to link up all important centres of population. The main telephone cables would each contain from four to five hundred speech channels. The equipment of the London telephone service with automatic exchanges would be two-thirds completed, and the automatic would have become the standard system in most provincial towns.

Correspondence.

OVERHEAD WIRES AND PRIVATE PROPERTY.

To the Editor of THE ELECTRICIAN.

Sir,—Further to your Editorial Notes on Overhead Equipment in this week's Electrician, as I have had untold difficulty over this matter I think the following observations might interest your readers.

Originally when roads were being constructed and fields divided the owners marked out a length 6 ft. wide, the earth from three of which they threw on to the other three to form a bank or "cop." In the centre of this they planted a hedge, the excavated portion becoming a ditch for irrigation purposes, so now in conveying land the hedge belongs to the man with the ditch. By the above you will see a landowner can only claim 18 in. from the centre of the hedge to the road, however wide the hedge or bank may be.

At various times walls have been erected which in course of time have become covered with soil, but this concealed wall is the boundary, as no sane man would set his wall back so as to present land free to the highway, and this boundary also applies to fences unless in the latter case there are only a few yards fixed in the centre of the bank to make good a dilapidated hedge.

Care should be taken, however, that no wire be over a bank or wall. In one case an owner looked up from the top of his garden wall and found my wire above it, and it cost me nearly £10 to remove.

Should trees be overhanging a road they are trespassing and the highway authority can demand their removal or, on giving due notice, can themselves prune or cut them, but the difficulty is for a private company to get the authority to move in the matter.

At the present time it is advisable to watch the Post Office, as they are overhauling all their overhead lines and are demanding very serious alterations, but I would far sooner deal with their engineers than with private landowners.

For small companies where there is, say, gas competition, it is better to get the prospective consumers to obtain wayleaves, as then the dispute and insults are between them and their neighbours.—I am, etc.,

C. A. Coppinger.

Bentham.
June 10.

RADIO TELEGRAPHY IN CHILE.

To the Editor of THE ELECTRICIAN.

Sir,—In your issue dated May 26 there appears the following paragraph under the heading "Submarine and Radio Telegraphy."

The Chilian Government concluded a contract in October, 1921, with the Siemens-Schuckert Co. for the erection of eleven radio telegraph stations at Santiago, Valparaiso, and Punta Arenas (all capable of communicating with Buenos Aires) and at Iquique, Antofagasta, Taltal, Tocopilla, Caldera, Concepcion, Valdivia and Chiloe, with a maximum radius of 1,550 miles. The contract price is $1 385 000, and the Telefunken system will be installed.

We should like to say that according to our information, that statement is incorrect, the Chilian Government not having concluded such contract with the Siemens-Schuckert Company or any other company.—We are, etc.,

Marconi's Wireless Telegraph Co., Ltd.,
Henry W. Allen,
Joint General Manager.

London, W.C.2.
June 7.

[This information was taken from the report of Mr. W. F. Scott, Commercial Secretary at Santiago.—Ed. E.]

Railway Companies' Power Supplies.

The inquiry by the Electricity Commissioners into the proposals of the S.E. and C. Railway Companies and the West Kent Electric Company for the erection of power stations at Angerstein's Wharf, Greenwich, and at Belvedere, respectively, was concluded on Wednesday.

West Kent Company's Scheme.

In opening the West Kent Electric Co.'s case, Mr. Tyldesley Jones said the Kent Electric Power Act of 1902 authorised the incorporation of a company to supply electrical energy in Kent. An Act of 1906 made some amendments, and authorised the company to supply to authorised undertakers, to anybody for power, and for lighting in any area which at the date of the Act of 1902 did not form part of the area of supply of any authorised undertaker. The company could be required to supply to authorised undertakers, and to anybody for power purposes, on terms which had to be settled by arbitration failing agreement. In 1909 the West Kent Electric Power Act was passed, transferring the powers and obligations of the Kent Electric Power Co. to the West Kent Electric Co. In the latter company's area for bulk supplies and for supply to railway companies were Dartford, Bexley, Beckenham, Penge, Chislehurst, Erith, Woolwich and other districts in which there were already authorised undertakers. The company could only supply for power within the limits of authorised distributors with the consent of the authorised distributors, or, if such consent be unreasonably withheld, with the consent of the Ministry of Transport. The company could, however, supply for railway traction purposes without the consent of any authorised distributor, and the energy could be used by a railway company anywhere on its system, with the consent of the Minister of Transport. Provisions in the company's 1917 Act removed all restrictions with regard to capital. They had expended over £155 000 on capital account. The company was promoted by the South Metropolitan Electric Light and Power Co. In 1917 it was determined to ask Parliament to remove the restrictions upon the development of the West Kent Co. as a generating company, and to enable it to perform the functions of a power company on a large scale. The money spent so far was found by the South Metropolitan Co. The bulk of the ordinary shares in the South Metropolitan Co. were acquired in 1918 by a group of companies including Vickers Ltd., and the Metropolitan Carriage, Wagon and Finance Co. The total issued and paid up capital of the South Metropolitan Co. (ordinary and preference) was £404 834.

Mr. P. C. Tempest, general manager of the S.E. and C. Railways, said he preferred that the railway companies should have their own generating station, as there would be less risk of failing to comply with the terms of the Government guarantee on the 6½ millions capital, viz. that the station should be completed in three years.

Financiers' Evidence.

Mr. R. McKenna, chairman of the City and Midland Bank, gave evidence as to the ability of the Metropolitan Carriage, Wagon and Finance Co. to finance the West Kent Co.'s project.

Sir E. Wyldbore Smith, chairman of the Metropolitan Carriage, Wagon and Finance Co., and a director of the West Kent Electric Co., said the former company were prepared to advance forthwith to the latter company, as a permanent investment, 3½ millions for the construction of the proposed station, laying mains, etc., and would be satisfied with a general return of 7 per cent. on the capital spent. The West Kent Co. s application to the Commissioners would be dropped unless an agreement were arrived at with the S.E. and Chatham Companies to supply energy to them. He believed the L.B. and S.C. Co., which had a contract with the London Electric Supply Corporation until 1927, would at some time take current from the West Kent Co. When that time arrived he believed the West Kent Co. would be able to supply more cheaply than the London Co.

Engineering Details.

Sir Philip Dawson, M.P., consulting electrical engineer, said he prepared the estimates for the West Kent Co.'s proposed station at Belvedere. In the first stage of the scheme there would be 100 000 kW of plant (in units of 25 000 kW each) running, and 50 000 kW of spare plant. The cost of the first stage would be £840 000. The West Kent Co. would be prepared to supply the S.E. and C. Companies three years hence at 0·575d. per unit, after transmitting the current 10 miles, assuming coal cost 15s. per ton. This charge for current would be varied as follows: The charge per kW per annum would be £4 5s. up to and including a maximum demand of 25 000 kW, and £3 5s. per kW for any excess above 25 000 kW, and then an amount equal to 0·252d. per kWh. As soon as all other demands outside the S.E. and C. Companies became equal to their demand, a rebate would be given them of 1 per cent., when other demands were double that of the railway companies they would be given a rebate of 2 per cent., and when the other demands were three times that of the companies they would be allowed 3 per cent. There must also be a sliding scale according to changes in cost of coal, rates of wages and improvements in machinery, which might justify renewals. Mr. Sparks's figure of 0·5d. for energy supplied at Lewisham was based on a thermal efficiency of 17·1 per cent. That was nearly 1 per cent. higher than he (witness) allowed for in a larger station with larger units and boilers. He allowed 16·2 per cent. The efficiency of his station should be 2 per cent. better than that of Mr. Sparks, according to his calculations, and assuming 15 per cent. efficiency for the Angerstein's Wharf station, that would increase the coal bill by 1·4 per cent. Assuming, also, 5 per cent. interest on the capital for the Angerstein station, instead of 4 per cent., and an addition of £0·31 to the £17·8 estimated as capital cost per kW of plant, an addition of £8 750 for cost of pilot and telephone cables, and £70 000 as the value of the generating station site, it brought the cost of current to 0·588d. At the 90 000 kW stage he estimated that Mr. Sparks's station would cost £18·2 per kW (compared with the estimate of £17·8), at the first stage—60 000 kW—the figure would be £18·45. A 150 000 kW station with 10 units of 15 000 kW must cost more per kW than his proposed station with 25 000 kW units. The greater the number of units the greater the cost per kW, and the smaller the units the more rapidly the cost increased. If Mr. Sparks' figure was correct for 150 000 kW, his figure for 60 000 kW was too small. On the debenture for £6 500 000 to be created by the Construction Co., it was agreed to pay interest not exceeding 6 per cent., so it was clear that 4 per cent., or even 5 per cent., was not the rate at which capital was expected to be obtained. He did not think many modern designers would plan a station with 10 units, particularly units as low as 15 000 kW. He had had information from all the railway power stations that were running. Higher steam pressures and higher temperatures were now being dealt with, but there were no stations running which enabled one to know the resulting increase in efficiency. The thermal efficiencies of some of the largest railway generating stations to-day were 9, 10, 11 and 12.

Advantages of Diversity.

Replying to Mr. Miller (for the S.E. and C. Companies), witness said he thought it could not be assumed that the efficiency at Angerstein's Wharf would be 17·5 compared with 14·2 at the South-Western power station at Wimbledon. The West Kent load, assuming they got the L.B. and S.C. demand, the S.E. and C. demand and a big industrial load, would give them an advantage over the S.E. and C. Companies' proposed station, because of the better diversity. It was not always a disadvantage to produce energy at two sites. It was an advantage if they had a big and a varied business and a high density factor, and could work their boilers at a high efficiency. It was a disadvantage to produce at two periodicities 50 and 25, but the S.E. and C. Companies had the disadvantage of a smaller demand and lower diversity factor.

Replying to the Commissioners, he said the West Kent Company would supply at the price which he suggested for the railway load (£4 5s. per kW per annum plus 0·252d. per unit, with reductions at certain stages) if the conditions as to power factor, etc., were similar. He did not think it followed that even if the price quoted to the railway companies proved unprofitable the general consumers would have to bear the extra cost. Four of the generators would be 25 cycle machines because that was the L.B. and S.C. periodicity, and two would be on 50 cycles, plus two converters to enable the higher efficiency to be obtained. The cost would be less for the same kW capacity if the plant were all 50 cycles. The extra cost was incurred because of the desirability of catering for the railway load, which would cheapen the general supply. If the S.E. and C. scheme were passed the general consumer would have to wait.

To Mr. Turner (for the Joint Conference of Local Authorities), Sir Philip said a Joint Electricity Authority, which included delegates of local authorities, could not compete with the railway companies as to price of energy. A private undertaking had to give its word to supply at a reasonable rate, but the Joint Electricity Authority would be able to charge what it liked to cover interest and sinking fund.

Re-examined by Mr. Tyldesley-Jones: The advantage the S.E. and C. had by having their generating station nearer Lewisham would be counterbalanced by the West Kent Company having increased generating facilities at Belvedere. The disadvantage in regard to transmission would tend to disappear as the load shifted eastward. The West Kent Company's charge to the railway companies would be 0·584d. with coal at 17s. 6d. Anybody else could be supplied at the same price under similar conditions. The price to the railway companies would come down to 0·55d. when other loads – the L.B. and S.C. and the industrial loads—were approximately equal to three times the S.E. and C. Companies' demand.

Replying to the Commissioners, Sir Philip said Mr. Sparks estimated a cost of £65 000 for cables from Angerstein Wharf to Lewisham. He (Sir Philip) suggested that with spares and pilot and telephone cables the total would be £200 000. He thought the 60 000 kW station could not be carried out for anything like the amount Mr. Sparks estimated. If the Commissioners assented to the West Kent Company's scheme orders for boiler plant and turbines could be placed within two or three weeks, and operations on the site could start at once.

Further Evidence for the Railways.

Mr. C. P. Sparks was recalled (for the S.E and C. Companies) and said 17·1 per cent. thermal efficiency had been obtained in stations with units the same size as those he proposed, and with a slightly lower load factor. Sir Philip Dawson had worked out the thermal efficiency on the basis of units delivered at Lewisham. He (witness) had calculated it on units sent out. About 18·1 might be assumed

for the larger station. The efficiency at the power station might be 1 per cent. higher than that at Lewisham. He did not think it could be substantiated that the power company were in a better position to give this supply than the railway company. Out of a demand of 57 000 kW the main load—43 000 kW—would be given at Lewisham, and the centre of gravity was in that neighbourhood. The railway companies started with an advantage of £155 000 as regarded expenditure in the first stage and at stage 1D that figure would rise to £310 000.

Trade Facilities Committee's Views.

Mr. W. J. SAINSBURY, secretary of the Trades' Facilities Advisory Committee, said, in reply to Sir John Snell, when the S.E. and C. Railway Companies first approached the Committee with regard to a guarantee they did not propose to generate their own power. The Committee said they would require to be satisfied that the power would be available when the line was ready for it. Later, when the railway companies proposed to generate the energy themselves, the amount was increased from 5 million to 6½ millions, but the guarantee was not to be given unless a satisfactory arrangement had been entered into for the supply of the power required. The Committee would be prepared to recommend a guarantee provided the Commissioners were satisfied that the power would be available when required, and that the price was acceptable to the railways.

In reply to the Hon. EVAN CHARTERIS (for the County of London Electric Supply Company) witness said he did not think the reduction of the 6½ million to 5 million would entail any delay.

To Sir HARRY HAWARD, he said a condition of the guarantee was that contracts for plant and equipment must be let to British firms, with the exception of small amounts for which sanction would be given for expenditure abroad. If the Commissioners decided in favour of the West Kent Company the Committee would instruct the consulting engineers that the contracts must be all placed on competitive prices, and that the Committee's sanction must be obtained for any purchase outside this country. These would be the conditions to whomsoever the guarantee were given.

Mr. TYLDESLEY JONES said it had been pointed out to him that the West Kent Company had not stated the load factor at which the 89 million units were to be taken by the S.E. and C. Companies. It was meant that they should take them with a load factor not less than 35 per cent. The maximum demand that had been specified was to be taken over half an hour or an hour. Coal cost was taken on a basis of 15s. and the wages were based on the present rates. He wished to explain more definitely the arrangement for reduction of the charge to the S.E. and C. Companies with the growth of the general demand. When the S.E. and C. Companies took 89 million units per annum, and the L.B. and S.C. and the industrial loads amounted to 216 million units the S.E. and C. would get the full benefit of the 3 per cent. rebate. The 1 per cent. and 2 per cent. rebates would apply when the S.E. and C. consumption was below 89 millions under the conditions stated. It was proposed that the agreement should be for 60 years and the terms of purchase were suggested to be 20 years' purchase on the average production for 5 years, subject to the parties being safeguarded if one or more of the five years were abnormal.

County of London Company's Case.

The Hon. EVAN CHARTERIS, opening the case of the County of London Electric Supply Company, said his clients had always taken the view that the capital station was the correct solution of the electric supply problem, would be able to give a supply at a price not higher than the railway companies could generate it themselves. The erection of a station for a specialised purpose was a proposition opposed to the interests of electrical development. The County of London Company were prepared to begin the construction on their Barking site of a 100 000 kW station.

Mr. CRAIG HENDERSON (for London County Council) pointed out that the Commissioners had issued a Memorandum last month stating that the consent given to the County of London Company for the Barking station was for the company's own needs. Notice ought to have been given of the company's intention to apply for sanction to supply the railway companies.

Sir JOHN SNELL said they must put in a formal application.

Mr. CHARTERIS said the Company were entitled to supply within their area, and the terms of their proposal would in due course be laid before the Commissioners. Cheap capital had to be considered in relation to the purposes for which the capital was to be used. Was it to be devoted to an economical purpose or squandered on a system which all the evidence of the last 10 years showed did not produce the best results and which was only to be justified in the event of there being no alternative which could commend itself to the Commissioners? Was the smallness of the cost of money commensurate with the capital saving which it would be shown could be effected by the County of London Company? Mr. Sparks said he started with a predilection for 50 cycles, which was used by the majority of authorities in the London district. He submitted that there would be no advantage in the adoption of 25 cycles. It was hoped that 50 would be the standard periodicity for London, and therefore it was a mistake to adopt 25.

Sir JOHN SNELL said if Mr. Charteris could show that the railway companies could still adopt the system they proposed to adopt if they used 50 cycles that was a matter the Commissioners must consider. His clients were not there to oppose the West Kent Company's application, except so far as putting forward an alternative involved criticism. It was estimated that there would be a capital saving of £483 000 by taking a supply from the Barking site, after allowing for transmission mains. £624 800 was the difference between (*a*) the station being erected for the purposes of the railway, and (*b*) the provision for the railway being part of the combined load, and the cost of the transmission mains being taken from the £624 000 brought it to £483 000, which was the saving in capital cost by combining the load compared with that at Angerstein's Wharf.

In reply to Sir JOHN SNELL, Mr. Charteris said if his company had the S.E. and C. load and constructed a tunnel under the river to contain the cables it was not suggested that it would necessarily take the place of the West Kent Company's proposed station. The cables through the tunnel would supply the County of London Company's area south of the river—which was the largest portion of its area. The question was whether the railway companies' load should be added to the County Company's load south of the river, thereby cheapening the whole supply north and south of the river. They had 30 000 kW industrial load, and were turning down demands for further supply owing to want of facilities.

Sir JOHN SNELL said that sanction was given on the Company's representations that it wanted the plant to comply with its statutory obligations. He understood that they wanted to shut down one or two of their existing stations on account of the risky condition of condensing water facilities.

On Tuesday, Mr. C. H. MERZ gave evidence on behalf of the County of London Company, and Mr. R. H. HOUGHTON was called for the railway companies.

Mr. W. F. FLADGATE went into the witness-box on Wednesday, after which counsel addressed the Commissioners.

Shanghai Electricity Undertaking.

The annual report and accounts of the SHANGHAI MUNICIPAL ELECTRICITY DEPARTMENT for the year 1921 have come to hand, and show the undertaking to be in a prosperous condition, further progress having been made during the year. The total capital outlay is now 20 771 469 taels (about £3 461 911) and on plant in operation 17 654 556 taels (£2 942 426), the return on the latter being 10·56 per cent., against 10·34 per cent. in 1920.

Year's Profits and Plant Extensions.

The gross profit on the year's working was 1 863 810 taels (£310 602) and the net profit, after meeting interest, providing for depreciation, etc., was 1 047 608 taels (£174 641), against an estimated amount of £171 636, and of £191 970 in the current year. From 1916 to 1921 a sum of 2 170 000 taels (£361 667) has been handed over to the general funds of the Council out of the profit of the electricity department, including £104 167 from the past year's revenue. The generating plant at the Riverside power station was increased by 46 000 kW (two 18 000 kW and one 10 000 kW sets), making the total capacity of the generating plant at that station 79 000 kW. Two 20 000 kW turbine sets and two 3 000 kW machines (the latter for providing independent supply for operating the auxiliary plant) are on order and will be available during next year. When these have been installed two 2 000 kW sets will be discarded, leaving plant of 121 000 kW at the station. The old Fearon-road generating station will also be shut down.

Cable Extensions and Sub-Station Development.

During the year 168 miles of overhead cable were erected and 66 miles of underground cable laid by the staff of the Department. The average capacity of the modern sub-stations is about 2 000 kW, though for supplying large mills and other purposes larger sub-stations have been equipped. The Tonquin-road "super sub-station" is already supplying 20 000 kW, and is being equipped to deal with 50 000 kW. At Robinson-road a large switch-house has been completed and is designed for ultimately handling 28 000 kW. The Department is now supplying electricity to 33 334 premises, an increase of 2 692 over 1920. The highest maximum load was 43 554 kW (Riverside 42 000 kW, and Fearon-road 1 554 kW), and the estimated maximum for 1922 is 64 000 kW. The load delivered to feeders was 41 074 kW, an increase of 16 per cent. Eight of the boilers have been equipped for burning oil fuel, experiments having shown that by supplementing coal-fired boilers with oil burners the steam capacity could be raised by about 25 per cent. The load factor has improved from 46·7 to 51·5 per cent.

The total units generated were 226 418 958, of which the Riverside station accounted for 219 251 888. The total units sold were 185 364 746, an increase of 28·24 per cent. over 1920. The largest increases were for power (over 38 million) and private lighting (over two million units), though the sales for public lighting, traction and heating and cooking were also larger. The new industrial power demands were not, however, as high as anticipated, but the existing consumers' requirements were higher. Owing to post-war conditions, delay in delivery of plant and other causes, the motors connected only amounted to 9 900 H.P., compared with 12 242 H.P. in 1920, which was a record year. The motor installations increase, but the number on hire shows a steady decrease, proving the popularity and established position of electric power. At present there are only 927 motors (of 15 888·5 H.P.) on hire.

Progress on the extensions at the Riverside station have not, it is stated, progressed as rapidly as might be desired owing to the amount of constructional plans required and to labour shortage.

Conference of Employers and Employed.

The first of a series of week-end conferences of employers and employed, which have been organised by the INDUSTRIAL LEAGUE and COUNCIL, was held on Saturday and Sunday last at the house of Sir Ernest Benn, at Oxted, Surrey. Among those present were: Mr. John Ames (general secretary Industrial League and Council), Sir Ernest J. P. Benn, Bart., C.B.E., Mr. W. Vincent Boby (W. Boby and Sons), Mr. H. J. Cash (National Federated Electrical Association), Major A. G. Church, D.S.O., M.C. (general secretary National Union of Scientific Workers), Sir Ernest Clarke, Mr. W. F. Dawtry (A.E.U.), Mr. H. H. Elvin (general secretary, National Union of Clerks), Sir Alfred Herbert (chairman, Machine Tool Trades Association), Mr. H. Wilson Howes (general secretary, Printing Machine Managers' Trade Society), Mr. K. A. Scott-Moncrieff (J.I.C. Electrical Supply Industry), and Mr. H. G. Williams.

Paper on Unemployment.

The Conference was divided into four sessions, presided over respectively by Sir Ernest Benn, Bart., C.B.E., Mr. H. Elvin, Sir Alfred Herbert and Mr. H. Wilson Howes. The subject for discussion was "The Fundamental Causes of Unemployment," and the case was presented by Mr. H. G. Williams, M.Sc., A.M.I.C.E.

Mr. WILLIAMS said that many excuses were given for unemployment, but in his view unemployment was due to bad trade. That was too often overlooked, and in consequence people sought to solve the problem of unemployment, instead of the problem of trade fluctuation which caused it. The immediate general causes of trade fluctuation were changes either in the volume or the direction of expenditure, or both combined. The Governments or large corporations had spent unwisely large sums of money. That had its present reflection on the unemployment in this country. The three causes of the changes in the volume of expenditure were :—(1) Economic disasters, (2) abstention from buying, and (3) inflation or deflation of currency or credit. Numerous disasters—*e.g.*, failure of harvests, war, revolution, industrial disputes—each deprived the people directly affected of their buying power, and that caused bad trade in other countries or industries. War, after its first stage, had the reverse effect when future production was mortgaged to raise loans. Abstention from buying might be caused by fear of war, revolution, abnormal legislation, bad trade, or resentment at high prices and the desire to reduce them.

Inflation and Deflation.

With regard to the inflation or deflation of currency and credit, the State or the banks, by the creation or destruction of credit in any way, *e.g.*, the printing of paper money or its withdrawal, the creation of book credits or their cancellation, could increase or diminish the amount of purchasing power available and thus raise or decrease the demand for commodities. Experience had shown that inflation or deflation produced appropriate reactions. Wherever deliberate inflation had taken place, disaster followed.

Unemployment was caused by changes in the direction of expenditure and changes which were partly changes in volume and partly changes in the direction of expenditure. Goods manufactured in anticipation of a demand which failed to materialise owing to a change of fashion become unsaleable, and persons who would have continued to produce such goods had to find fresh employment. Capital sunk in such products would be lost wholly or in part. In changing production the employer had a tremendous responsibility placed upon him, and should endeavour to make arrangements for displacing as little labour as possible.

Changes of State policy also tended to cause unemployment. Extravagance in spending an undue proportion of individual or national income on goods of immediate consumption and not enough on capital goods, *e.g.*, factories, machinery, railways, etc., would render idle both plant and people in constructive industries, and had its influence on the future efficiency of other industries.

Improved Methods.

Increase in the efficiency of firms in one part of the country might throw temporarily out of employment numbers in the same trade in another part of the country, and the same applied to firms producing goods in another country of the same quality, but at a cheaper rate. Improved methods resulted in cheaper production because each person's output was increased. The ultimate effect was to increase the demand through lowering prices. The immediate effect of it might be the temporary unemployment of some of the men. Those, however, were much more readily taken up when an increase of output was increasingly distributed.

It was possible for bad trade to be avoided, but only if all the causes which led to it were removed. Some of the causes were beyond human control, while others could be completely avoided if everyone was not only good but also wise. Better understanding of the consequences of the unwise acts on the part of Governments and employers and of workpeople which led to trade dislocation, and the more we could educate people on those lines the less bad trade we should endure in future.

There was a considerable need for an economic fly-wheel, which, like the fly-wheel of an engine, would take up undue speed and assist to regulate action when energy was reduced. In that way, during periods of prosperity, the State, municipalities and Governments should accumulate the funds needed for capital expenditure and use them when trade was slack.

Resolution of Conference.

There was considerable discussion, in which all those present took part. The conference, at the last session, unanimously passed the following resolution :—

"That this week-end conference of employers and employed after considering 'The Fundamental Causes of Unemployment,' find that discussion discloses varied and complex causes of unemployment which are unknown to the great majority of the people; they are of opinion that the incidence of unemployment should be fully inquired into and they respectfully recommend to the Joint Industrial Councils and Joint Interim Reconstruction Committees that each Council should appoint a special committee of inquiry who shall make a full investigation into the whole question of unemployment as it affects each industry and that each Council be requested to issue individual reports of each inquiry."

Efficiency of Wireless Watchers.

The report of the MERCHANT SHIPPING ADVISORY COMMITTEE, which was appointed in December last to inquire into the efficiency of wireless watchers, has been issued. The committee (of 12 members) state that they have had the advantage of hearing the views of representatives of the Association of Wireless Telegraphists, of witnesses nominated by the Shipowners' Parliamentary Committee, the Institute of Marine Engineers and the Imperial Merchant Service Guild, and of Commander F. G. Loring, R.N., of the General Post Office. The time at the disposal of the Committee was, however, not sufficient to enable the members thoroughly to investigate the cases submitted by the Board of Trade. As, however after examination of the cases it appeared that in only four of them was technical inefficiency on the part of watchers alleged, the committee consider that even if the allegations made should on further inquiry be sustained, they do not afford ground for advising any alteration in the present regulations.

At the same time, the evidence reveals in some cases a want of friendly co-operation between operators and the watchers, and the committee are of opinion that shipowners, masters and seamen's organisations should be impressed with the desirability of taking all steps open to them to encourage such co-operation in the interests of all on board. Further, watchers should not be removed from their duty during their period of watch.

In a reservation by Mr. J. Henson it is stated that if technical inefficiency is proved that justifies alteration in the regulations, and also that an alteration is required providing that before a certificate is issued by the Post Office to any person acting as a watcher, more technical knowledge should be required.

"Permoil" Lubrication.

LOCO AND AUTO ECONOMY ACCESSORIES, LTD., of 183, Westminster Bridge Road, London, S.E.1, have devised the "PERMOIL" system of greasing for axle boxes which, it is claimed, when once installed, requires no re-oiling until after 60 000 miles running on a railway coach or wagon and 90 000 miles on a tramcar. A special oversized pad, constructed of horsehair and wool, is used. This is strung together to keep its form, and is so arranged as to keep its tension like a collection of springs. This special construction prevents the usual rapid compression of the packing. The pad is soaked in a specially prepared oil which has a viscosity of from 15 to 16, and is without impurities or acid content. After 60 000 or 90 000 miles have been run a fresh supply of oil poured on the pad will enable another run of similar length to be made before the pad is discarded. The initial cost of filling an axle box is only 10s. to 12s. 6d., and the cost per mile on a life of 90 000 miles is about 0·01d. compared with 0·24d., which is said to be the lowest figure reached under the old system. The old method of using a wick to conduct oil from a container to the pad is entirely dispensed with. The thin layer of the "Permoil" lubricant between the bearing and the axle gives the lowest possible coefficient of friction without loss of permanence of the film, and a dry or semi-dry condition of the bearing does not occur, even under the greatest pressure. The "Permoil" E.B.5 lubricant, which is used for railway and tramway axles, is said to act perfectly in the hottest climate without getting thin and down to 30 degs. without congealing. It is not necessary to change the construction of axle boxes in order to instal the system.

A table prepared by the company shows comparative results of tests with the "Permoil" system and with ordinary oil lubrication. On a G.E. 52 motor one charge of ordinary lubricant in summer gave three days' running on an axle bearing and two days on an armature bearing, compared with 120 days and 160 days respectively with the "Permoil" system. With a G.E. 800 motor the figures were three days and one day with ordinary lubricant and 100 days and 80 days with "Permoil." In winter the figures were with ordinary lubricant four days (axle) and three days (armature) on a G.E. 52 motor, and six days and four days on a G.E. 800, while with the "Permoil" 160 and 140 days were run on the G.E. 52 and 150 and 130 days on the G.E. 800.

The "Permoil" system is now being used on the Great Western Railway, amongst other traction undertakings, and it is said to be regarded with favour by the managers of many railways and tramways. Tests will be made shortly on the L.C.C. Tramways.

Association of Consulting Engineers.

The annual general meeting of this association was held on the 29th ult., Mr. W. Vaux Graham, M.I.C.E., presiding.

The report of the committee stated that nine new members (including one from Cape Town and one from Calcutta) were elected during the year, the total membership being now 84. A letter was received last summer from the Belgian Association of Consulting Engineers inviting the association to attend a meeting in Paris in connection with a proposed International Federation of Consulting Engineers, but after consideration it was decided that no useful action could be taken at present. Owing to the coal strike, the annual dinner was postponed until November. The result showed that this period of the year was more convenient than the spring and it is proposed this year to adopt the same course.

Conditions of Contract.

The association had a representative on the Committee of the I.E.E. to revise the model general conditions of contract, but during the year it became evident that the association could not accept the conditions in the form in which they appeared likely finally to take, and the representative was withdrawn. After discussion with representatives of the B.E.A.M.A. it was decided that the association should itself draft a set of conditions for use where members of the association and members of the B.E.A.M.A. were jointly concerned. A draft was accordingly prepared by a sub-committee. One principle underlying these conditions was that the responsibility for the design of the works should rest with the engineer, and that the work should be carried out to his instructions and satisfaction, but that in the event of the contractors being dissatisfied with any of his decisions they should have the right to refer the matter to an independent arbitrator, who should hold a single arbitration on the completion of the work to decide whether such decision of the engineer had entailed additional expense to the contractor. This principle was mutually approved, and the conditions were agreed, except clauses 27 and 34. These were held over for further discussion at the end, as the committee found themselves unable to accept the limitations of the B.E.A.M.A.

Limiting Contractor's Liability.

The first was an addition to clause 27, limiting the liability of the contractor for damage or loss caused to the purchaser, owing to neglect by the contractor or to improper workmanship or design of the plant, to a sum not exceeding the value of the contract. The B.E.A.M.A. claimed that such a clause had already been included in the draft agreed by the representatives of the I.M.E.A. on the Committee of the I.E.E. The committee of the A.C.E., however, felt that as the liability of contractors to make good such damage was not limited under Common Law, they could not agree to recommend the members to put before their clients a set of conditions by which the contractor was relieved of this legal obligation. The addition to clause 34 limited the penalty of 1 per cent. of the contract value of any portion of the plant for every week by which the "Time of Completion" was exceeded, to 25 per cent. of such contract value. Unfortunately the B.E.A.M.A. finally decided that without the inclusion of these two additions the conditions could not be issued as agreed, but as so large a measure of agreement had been arrived at, the committee issued them in the name of the association and recommended its members to make use of them, leaving the B.E.A.M.A. to raise those questions in any particular case.

The report and accounts were adopted, and the following members were elected to serve on the committee:—*London:* Mr. A. T. Cooper, Mr. J. Mitchell Moncrieff, C.B.E., Mr. Arthur Henry Preece, Mr. Henry John Rofe. *Country:* Mr. Harry Prescot Hill (Manchester) and Mr. John Alex. Warren (Glasgow).

Electricity Companies Officers' Association.

In the 1921 report of the Executive Committee of the Association of Officers and Staff Members of Electricity Companies of Great Britain it is stated that Sir Alex. B. W. Kennedy, F.R.S., has again kindly consented to accept the Presidency of the Association. Mr. F. Wood has resigned his seat on the Committee and the hon. treasurership of the Association, and Mr. A. C. Tappenden (of the City of London Company) has undertaken the duties of hon. treasurer. The Committee have watched the proceedings at the local inquiries of the Electricity Commissioners with the view of keeping before the Commissioners the desirability of the foundation of superannuation schemes by any new authorities.

In regard to the Morley award, the Committee are of opinion that all questions as to the detriment suffered by officers and servants of an undertaking by operations under the 1919 Act would best be dealt with by referees fully acquainted with the nature of the industry; and they have (in conjunction with other Associations) submitted this opinion to the Electricity Commissioners. Many of the powers of combination conferred on undertakers by the Act of 1919 are similar to those given by the Acts of 1908 and 1909, but any such combination as may take place in future will be in consequence of the Act of 1919, and the Committee think that any member who may suffer detriment should be entitled to the protection given by Sec. 16 of that Act. They were afforded an opportunity of laying their views before Sir John Snell and Sir Harry Haward, with the result that a new section has been inserted in the Bill now before Parliament favourably amending the section.

The accounts shows a credit balance of £517 12s., which sum, except for the amount which it is necessary to keep on current account, has been placed on deposit at the bank. The members of the Executive Committee who retire are Messrs. V. A. Hitchman, W. A. Mackenzie, A. W. Seabright, and J. H. Willis. Mr. Mackenzie has resigned his seat, but the other gentlemen offer themselves for re-election. The hon. secretary (Mr. O. M. Andrews) having found it impossible, owing to other engagements, to devote the necessary time to the business of the Association, an assistant hon. secretary (Mr. R. Litt, of the Westminster Company) has been appointed.

Small Ironclad Cut-outs.

In Henley's new pamphlet dealing with CUT-OUTS we notice that the company have made a departure which will be appreciated by many engineers. Extracts are given of tests carried out at the National Physical Laboratory, part of which we produce below. With this information confidence can be reposed in a cut-out, whereas previously the performance of a cut-out depended too much upon theoretical assumption. In many cases engineers, for the sake of safety, install a higher capacity cut-out than is necessary. Obviously this is an expense which could be reduced considerably.

The Henley "Isco C" cut-out, dealt with in this pamphlet, is rated for a working current of 10 A and a fusing current of 30 A, and the test certificate of the National Physical Laboratory states that:—"The cut-outs are rated for 10 A 250 V, fitted with fuse wire of 0·018 in. dia. tinned copper. A battery of 1 000 Ah. cells giving 240 V was used for the test. The resistance was adjusted to give a short circuit current of 1 000 A. The positive pole of battery was connected to the top terminal and also with a resistance of 0·100 ohm, to the earthing screw of the metal box, the negative

FIG. 1.

pole being connected to the bottom terminal. The result of five tests was as follows: The fuse opened the circuit clearly without arcing. The blowing of the fuse blackened the asbestos lining in the lid, but this was purely superficial."

There are a number of other interesting features in this Henley cut-out, including a patent slam catch and sealing device (shown in Fig. 1) so that there is no loose sealing pin to wrestle with; the

FIG. 2.

carrier is fitted with self-aligning contacts, and solid brass terminals fitted with a pair of brass cheesehead pinching screws. These cut-outs are specified for a *working current* of 10 A, and Messrs. Henley inform us that although the fusing current of this new cut-out is 30 A they consider it is more important that engineers should know the actual working current. This is, or should be, standard practice. We also illustrate a Home Office type of fuse carrier, showing the method of wiring and the patent self-aligning contacts. A copy of pamphlet W.L.3 may be obtained from W. T. Henley's Telegraph Works Co., Blomfield Street, London, E.C.2.

Legal Intelligence.

Re Corona Lamp Works, Ltd.

A petition by the British Thomson-Houston Co. for an order to wind up the Corona Lamp Works, Ltd., came before Mr. Justice Astbury on Tuesday.

Counsel for the company asked for an adjournment. He said the petition was the result of an appeal to the House of Lords for a decision of the Court of Appeal. There was a sum of £5 529 from costs which were ordered by the House of Lords to be repaid to his clients. There was also a subsequent action, tried by Mr. Justice Astbury, between the same plaintiffs and defendants, and that resulted in judgment against defendants. It was alleged in the petition that negotiations had taken place for a compromise on the different matters between the parties, and the matter was allowed to stand over for some scheme to be carried through. Unfortunately, while the negotiations were pending the petitioning creditors put in an execution on the goods of the company. A receiver was appointed by the debenture holders, and the sheriff came out. Then the petition was launched. If the negotiations had been allowed to proceed the Corona Co. had every reason to believe that there would have been no necessity for the petition, and a scheme would have been brought forward to satisfy everybody. The nominal capital of the company was £2 000, but there were debentures in three classes for £32 000; and the receiver was in possession. He asked that the petition should stand over for a month to allow of the negotiations between the petitioners and the company to be continued.

Mr. Turner (for the petitioners) said his instructions prevented him making any concessions.

His lordship then made a compulsory winding-up order.

Is a Motor Repairing Waggon a Tractor?

Sheriff Robertson, of Falkirk, has given his considered judgment in the case against the Falkirk and District Tramways Company for having used, on February 26 last, a motor tower repair waggon for which a licence under the Finance Act, 1920 (as amended by the Roads Act, 1920), was not in force. The company had applied to the Stirling County Council for a licence, for which a postal order for 5s. was enclosed, but the Council, not being satisfied that that was the appropriate duty, declined the 5s. and communicated with the Ministry of Transport, who expressed the opinion that the correct duty payable on the vehicle was £25. The company maintained that the waggon, which was not used solely in the course of trade or agriculture or in carrying goods from one place to another, was a tractor, and should be licensed as such at 5s.

In the course of his judgment, the Sheriff said that for effecting the repair of the overhead wires the company used a motor tower repair waggon, which was an ordinary four-wheeled lorry propelled by an internal combustion engine capable of developing 24 to 25 H.P. On the front part of the lorry there was a telescopic tower, by means of which a platform could be raised to enable workmen to carry out repairs to the wires. The rear part of the lorry contained a box, in which tools, pieces of spare wire and other fitments necessary for the repairs were carried. The Finance Act of 1920 provided that on mechanically propelled vehicles used on public roads duties should be paid at the rate specified in the second schedule of the Act, but for vehicles used solely in the course of trade or in agriculture (locomotive ploughing engines, tractors, and other agricultural engines) the duty was to be 5s. If the vehicle was not a "tractor," the company's argument failed. He could not conceive any definition which would be wide enough to include the vehicle in question that would not also include every motor lorry used to carry any kind of burden. The general feature of all "tractors" must be that they draw their burden behind them and do not carry it. He had no doubt but that the company when they asked for a licence failed to tender the appropriate amount of the duty payable by them. Therefore he imposed a fine of £10, three guineas of which he allocated to the County Council.

Parliamentary Intelligence.

Key Industries.

In the House of Commons on Monday, Mr. S. BALDWIN stated, in reply to Major Mackenzie Wood, that he was aware of Sir J. J. Thomson's general attitude on the Safeguarding of Industries Act and on the alleged difficulties in getting apparatus for research. He would point out, however, that the inferiority of apparatus and materials could not be ascribed to that Act, since there was no prohibition of importation, and the duty was not of sufficient magnitude to deter an investigator from obtaining foreign goods if their quality was appreciably higher than that of domestic products. There was conclusive evidence that Germany was far from maintaining her pre-war standard of quality. He could not consider Sir J. J. Thomson's suggestion that a system of licences under the Act for research institutions should be set up.

Supply Companies Charges.

Answering Viscount Curzon in the House of Commons on Monday, Mr. A. NEAL stated that the increases in the maximum charges authorised to be made by electricity authorities had sometimes been made under the terms of their provisional orders, which incorporated Sec. 32 of the Schedule of the Electric Lighting (Clauses) Act, 1899, but in the majority of cases under the Statutory Undertakings (Temporary Increase of Charges) Act, 1918. In each case the Minister had considered a report by the Electricity Commissioners, and under these circumstances he did not think that the appointment of a Committee to deal with the matter would be useful.

Suburban Railway Electrification.

On Monday, Mr. J. D. Gilbert put a long question to the Minister of Transport on the subject of the electrification of the suburban lines of the S.E. and C. Railway Companies. Mr. Gilbert asked whether, seeing that the Government had undertaken to guarantee capital expenditure of six and a half millions by the companies for their electrification scheme; that it was a condition of the guarantee that the work should be started at an early date and be carried out within three years, and that the generation of the necessary power should be done at cost price; that the formal application of the railways for consent to erect a generating station was opposed by the West Kent Co.; that the latter company were themselves promoting a scheme for putting up a station at Erith; that practically all the shares in the West Kent Co. were owned by the South Metropolitan Co., who had recently joined a large group of London electricity companies; that the opposition of the West Kent Co., if successful, was likely to delay the electrification of the railway lines and to increase the cost of power supply for the lines; and that the erection of a non-purchasable capital station at Erith would seriously affect the purchase rights of the London County Council, he would state whether the Advisory Committee under the Trade Facilities Act were aware, when they came to the agreement to assist the railway companies, that the consent of the Commissioners would be necessary for putting up the station; and whether there was any consultation between the Treasury and the Ministry of Transport on the subject?

In reply, Sir R. HORNE said the answer to both parts of the question was in the affirmative. He must not, however, be taken to concur in all the statements of the preamble, many of which were matters for argument.

Motor Transport by Railways.

On Monday it was announced that, owing to the opposition, it had been decided to withdraw the L. AND N.W. AND MIDLAND RAILWAY BILL for road transport powers.

Overhead Transmission Line Material.

B.S. specification No. 137 for PORCELAIN INSULATORS FOR OVERHEAD POWER Lines, the first of a series covering overhead transmission line material, has been issued by the British Engineering Standards Association, and copies may be obtained (at 1s. 2d. each) from the Secretary.

In preparing the Specification the Committee considered that, in view of the number of designs available at present, none of which could be said to represent finality, it was not desirable to standardise the shape or dimensions of the insulators. The Specification is, therefore, confined to the conditions of test and performance of two types of insulators. Considerable difficulty was experienced in finding suitable terms for these types, and finally the terms "Supporting" and "Tensioning" were adopted. They are defined as follows:—

"Supporting Insulator" denotes one which supports the conductor but is not intended to withstand the load due to the full tensile stress in the conductor. Pin type supporting insulators are generally used for declared pressures up to about 60 kV and suspension type are employed generally for declared pressures in excess of 60 kV.

"Tensioning Insulator" denotes one which is designed to withstand the load due to the full tensile stress in the conductor. Tensioning insulators are of the disc and shackle type, but the latter are practically obsolete. Disc type insulators are divided into interlinked and metal hooded types.

I.E.E. War Memorial.

The unveiling and dedication of the WAR MEMORIAL in memory of the members of the Institution of Electrical Engineers who fell in the Great War will take place at the Institution building on Wednesday, the 28th inst., at 4.30 p.m. The Memorial will be dedicated by the Rt. Rev. Bishop Ryle, K.C.V.O., D.D., Dean of Westminster, and unveiled by Air Chief Marshal Sir H. M. Trenchard, Bart., K.C.B., D.S.O., assisted by the President of the Institution, Mr. J. S. Highfield, and the Senior Vice-President Dr. W. H. Eccles, F.R.S.

The Entrance Hall, where the Memorial will be erected, will be reserved for nearest relatives, and special tickets will be issued to them for this purpose. Members (other than relatives) and their ladies will take their places in the lecture theatre, for which no tickets will be required. It is requested that those attending should arrive not later than 4.15 p.m., and it is desired that officers who have uniforms should attend in service dress with decorations.

Electricity Supply.

For the year ended March 31 the Bacup Electricity Department made a profit of about £29.

KENDAL Town Council have decided to spend £11 685 on extensions and plant in connection with the electricity undertaking.

CANTERBURY City Council has applied to the Electricity Commissioners for a loan of £4 650 excess expenditure in respect of new generating plant.

DUMFRIES Town Council has now received the terms upon which the undertaking of the Electricity Company can be acquired, and the offer is to be investigated.

BLACKROCK (Dublin) Urban Council have applied to the Provisional Government for a Special Order to authorise the supply of electricity in the township.

GLASGOW Electricity Committee have decided to purchase 240 000 tons of coal during the next twelve weeks at a price which is about 10s. a ton less than last year.

BLACKPOOL Tramways and Electricity Committee have decided to allocate £4 000 of their balance of £6 286 to reserve fund, and £1 000 to third-party insurance, carrying forward £1 236.

A meeting of residents of ABBEYFEALE (co. Limerick) was recently held in support of a scheme for the formation of a company to establish electricity works. Canon Cregan presided over a representative gathering.

WORKSOP Urban Council is being sued by the Grafton Angling Association for damage caused by alleged negligence in permitting heated water to enter the Chesterfield Canal from the condensing plant at the electricity works.

BLACKPOOL Electricity Committee will support the scheme for the improvement of the existing organisation for the supply of electricity in MID-LANCASHIRE ELECTRICITY DISTRICT, and for setting up a Joint Advisory Board.

The large power consumers having complained of the high charges for electricity, the Corporations of both Bacup and the adjoining Borough of Rawtenstall are in negotiation with a view to a new scale of charges being adopted in the two towns.

Mr. A. Ellis, of Cardiff, who was appointed to report on HULL electricity undertaking, states in his report that if it was a case of wishing to find work for the unemployed he would say the Committee had succeeded beyond the limits of anticipation.

The institutions under the control of the BLACKBURN Guardians are apparently quite up to date, for Mr. P. P. Wheelwright, who is acting as electrical adviser to the Board, has been instructed to instal six electric irons at the laundry, and also to lay a cable to the Sanatorium.

Owing to the delay in making known the proposals for dealing with electricity supply in the area which includes BURLEY-IN-WHARFEDALE, the Urban Council find themselves unable to proceed with their scheme for providing public and private electric lighting in the village.

On February 23, STEPNEY Borough Council applied to the Electricity Commissioners for sanction to a loan of £492 140 for extensions to the electricity undertaking. They have now received permission to borrow £268 000 on account, a former sanction to £125 000 for the same purpose given in May, 1921, being cancelled.

The Bursar of MARLBOROUGH College has applied to the Town Council for permission to carry cables under and above roads in connection with an electric lighting scheme for the college buildings and boarding-houses. It is suggested that the Council should take advantage of the scheme by endeavouring to obtain a supply of electricity for the town.

CROOK (co. Durham) Urban Council are applying for a Special Order to authorise the Council to purchase, and the County of Durham Electrical Power Distribution Company to sell, so much of the company's undertaking as is situate in the Council's district, to authorise the Council to take a supply of electricity from the said company or any other body or person, etc. Objections to the Electricity Commissioners by July 10.

HACKNEY Borough Council have passed a resolution asking the Electricity Committee to consider and report on the question of initiating a scheme whereby electricity for all domestic purposes may be made available to families of limited means without the necessity of appreciable initial expenditure; and requesting the borough electrical engineer to prepare a report on the matter for submission to the Electricity Committee.

The Electricity Commissioners have informed BACUP Corporation that although the town has not been included in the S.E. Lancashire Electricity District, that fact does not preclude the possibility of Bacup obtaining a supply or giving a supply of electricity to an authorised undertaking or to a consumer in that district if it be established that such a course is the most economical and is in the best interests of the parties concerned.

Colonel Ekin held an inquiry last week into the application of LYME REGIS Town Council for a Special Order to enable them to purchase the undertaking of the Lyme Regis Electric Light and Power Co. It was stated that the purchase price agreed upon was £3 750, and it was proposed to expend an additional £8 000 on extensions and improvements. The price charged by the Company was 1s. per unit, and it was proposed to increase this to 1s. 2d., with a maximum charge of 1s. 6d.

ST. PANCRAS Electricity Committee, in a report on the Council's scheme for supplying electricity to small dwellings, states that at present there are 285 consumers, and that Flaxman Terrace and Prospect Terrace Dwellings have been wired for 488 lights, but the supply to these houses has been delayed pending a decision of the Special (Housing) Committee as to the wiring of the staircases, the caretaker's residence, etc., as the tubing for the rising mains can be utilised for both schemes. Instructions have now been given for the work to be proceeded with.

The fourth and last of the new gas-driven sets for BUXTON electricity undertaking has been installed, and it is confidently anticipated that the works, which have shown a loss since 1918, will now show a substantial profit. The loss for 1918 was £1 863; for 1919, £2 057; and for 1920, £3 378. But when the first portion of the new plant was installed matters began to improve. In 1921 the loss was reduced by £2 000, by a further £400 in March, 1922, and would have been wiped out if the coal strike had not occurred. It is hoped soon to reduce the charges to consumers.

New Schemes and Mains Extensions.

The NAVAN (Ireland) Urban Council have started work in connection with the erection of the new electricity works.

YORK City Council have applied for sanction to loans of £1 200 for two air filters, £2 000 for transformers, and £3 000 for services.

CHEADLE (Lancs) Council has decided to canvass the residents in Cheadle Road in order to ascertain the demand for electricity supply.

FORMBY (Lancs) Council have received offers of electricity supply from Liverpool and Southport Corporations and the L. & N. W. Railway Company.

WARRINGTON Rural Council will consider at their next meeting the application of the Corporation for authority to lay an extra cable along Padgate Lane.

HASTINGS Corporation Council has applied for authority to borrow £7 000 for mains, including £1 113 over-spent, and £5 418, excess expenditure on various loans.

The Electricity Commissioners have sanctioned the borrowing of £26 050 for electricity extensions at LYTHAM and ST. ANNES, where there are now 3 222 electricity consumers, against 2 553 last year.

The talk of utilising IRISH WATER POWER for generating electrical energy is still going on, but it is obvious that no real progress in that direction can be achieved till a calmer political atmosphere prevails.

ELGIN Town Council are supporting an application by Edmundson's Electricity Corporation for a Special Order authorising the supply of electricity in the burgh. A limited company is to be formed with a capital of £20 000.

HENLEY-ON-THAMES Council have before them two schemes of electricity supply, one being by means of overhead cables from Reading, which would also link up other parishes, and the other by utilising the water-power of the river.

Messrs. Armstrong, Whitworth and Co. have obtained an extension of time from INVERNESS Town Council in regard to the Loch Luichart hydro-electric scheme. The firm have alternative proposals for utilising the water-power of the Caledonian Canal.

BURY (Lancs) Corporation has applied to the Electricity Commission for sanction to borrow £2 700 for laying a third main between Chamber Hall and Rochdale Road power stations, and the permanent laying of the two existing trunk mains along Tanpits Road.

HAWARDEN Rural Council has applied for a Special Order to authorise the supply of electricity in Connahs Quay Council area, but the application is opposed by Chester Corporation, who have applied for an order to distribute electricity within a radius of five miles of Chester, and also by Wrexham Corporation

The question of providing additional generating plant is being considered by CARNARVON Corporation. Ald. J. Pritchard, chairman of the Electricity Committee, explained at last week's meeting that the proposed plant would cost about £8 000, while the cost of providing bulk supply from the North Wales Power and Traction Company would be about £12 000. The arrangement with the National Construction Company would end in three years, but there was an understanding by which the period might be extended to eight years.

An inquiry was held at LIVERPOOL on Tuesday into the application of the Corporation for a special Order to authorise the purchase of the Bootle Municipal Electricity Works and to extend the Liverpool area of supply to Bootle, Litherland, Waterloo, Seaforth and Great Crosby. The inquiry was conducted by Col. Ekin, and there was no opposition, save from a section of Bootle ratepayers, who demanded an annual payment of £12 500 to Bootle, instead of the £7 500 agreed upon by the two corporations, and for a periodical review of the price per unit to be charged to Bootle consumers.

Electric Traction.

BLACKPOOL Tramways Committee has declined an offer to rent the electric standards for advertising purposes.

BURNLEY Tramways Committee has applied for sanction to borrow £4 950 for relaying the double line between Park Lane and Padiham, and a single line in Manchester-road to Towneley, and Rosegrove.

Work was started on Monday last on the schemes for the improvement and extension of the railways of the UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON. Part of the City and South London line will be closed on August 8, when the widening of the tube will be commenced. The first sod of the ground for the Edgware extension was cut on Monday.

GLASGOW Tramways Sub-Committee are to consider and report on the revision of fares and the improvement of the services.

The wages of the tramway employees were reduced by 3s. a week on June 1, and by a further 2s. on the 1st prox.

The shareholders of the GLASGOW SUBWAY CO. have now authorised the sale of the undertaking to the Corporation for £385 000. It is probable that electric traction will be adopted when the transfer has taken place.

For some time the tramways department has been employing men each alternate week on relief work, and under arrangements with the Employment Exchange these men received an out-of-work donation for the week of enforced idleness. The Ministry of Labour has decided that this practice must be discontinued, and men employed on such terms are not to get the out-of-work donation in future. The Tramways Committee are endeavouring to secure the continuance of the practice.

It is reported that satisfactory trials have taken place of the NORTH EASTERN RAILWAY CO.'s new electric passenger locomotive. It is intended to haul a 450-ton express train at an average speed of 65 m.p.h., but the running gear is designed for a maximum safe speed of 90 m.p.h. The trials are stated to have clearly indicated that the full h.p. for which the engine was designed—1 800 h.p. one-hour rating, or 1 260 h.p. continuous rating—could be developed, and that the heavy gradients could be dealt with in the manner anticipated.

The demand for a reversion to penny tram fares was renewed at last week's meeting of LIVERPOOL City Council. It was stated that since the minimum twopenny fare was introduced about eighteen months ago there had been a falling off of passengers amounting to 40 000 000 per annum. Councillor Wilson, chairman of the Committee, said an effort would be made to cheapen fares towards the end of the present year, but the department must first get out of debt. Liverpool was paying higher wages to its tramway employees than any other municipality in the country, and nowhere were there better cars or better tracks.

The inauguration of the electric train service between Goldau and Lucerne on the 28th ult. completed the ELECTRIFICATION OF THE GOTTHARD RAILWAY, about 140 miles in length. The steam line was opened in 1882 and work on its electrification began in 1913. The scheme, which was delayed by the war, also involved strengthening some bridges and viaducts. Electrical energy is supplied by Lake Ritom hydro-electric station but as soon as the Amstey power station is capable of furnishing a supply the electric service will be extended to the Lucerne-Basle line. Some particulars of the electrical equipment have already appeared in THE ELECTRICIAN.

The proposal of GLASGOW Corporation to purchase the Airdrie and Coatbridge Tramways is severely criticised in the report issued by the Ratepayers' Federation. It is thought that the present is an inopportune time to purchase the tramways. The Federation are, apparently, reconciled to a railway monopoly but a tramway monopoly is to be opposed, for the report states: "Were it proposed simply to link up Glasgow tramways with those of another burgh no objection could be offered, but it was a different matter for municipalities to borrow money in order to create great tramway and omnibus monopolies, which in turn were to become destructive of the capital supplied by the same public to run the railway companies." It is also objected that though the Corporation are now promoting a Provisional Order to purchase the tramways they paid the purchase price of £82 250 in December last. The purchase scheme has been before the ratepayers for a long time and the promotion of the Order was approved. In fact as no petitions have been lodged against the Provisional Order it is now proceeding as an unopposed measure.

A large installation of ELECTRICALLY OPERATED SUGAR PLANT, consisting of centrifugals, has been sent to JAVA by Pott, Cassels & Williamson, of Motherwell. The centrifugals have been delivered to the Tjomal sugar factory, and comprise 73 electrically driven units, arranged in two double rows, batteries of 42 and 33 machines respectively, with steel baskets, 36 in. dia., 18 in. deep. Each machine has its own 3-phase overhead motor, running at 1 200 revs. per min. The centrifugals are driven by the motors through a special form of friction clutch which also acts as a flexible coupling between the motor and centrifugal. The switches are also of special design and are interlocked with the brakes of the centrifugals. Each of the four distributing mixers has its own motor, operating through suitable bevel and worm gear. There are altogether 83 electric motors.

Municipal Accounts.

WALSALL MUNICIPAL ELECTRIC TRAMWAYS DEPARTMENT shows a net profit in the year ended March of £3 987, compared with £3 107 in the preceding year.

The profits of the WALSALL ELECTRICITY SUPPLY DEPARTMENT for the past year amounted to £1 110, compared with £1 613 in 1921. Receipts from the sale of current fell from £94 658 to £85 117, but generating expenses dropped from £10 458 to £7 935, and management expenses from £6 556 to £5 944.

ABERDEEN Corporation Tramways department has completed a record year. The total revenue of the tramways and motor omnibuses was £196 119, against £195 312 last year. There was a decrease of £6 968 on the tramways, but an increase on the 'buses of £7 775, or a net increase of £807. The estimated net profit will be about £2 248.

The net profit on the past year's working of the SWANSEA electricity department was over £3 400, although there was a large drop in consumption owing to trade depression. In 1920–21 the profit was £3,878. Arrangements have been made for the construction of a railway siding at the electricity station which will effect a saving of 2s. 6d. per ton on coal delivered, or £2 000 a year.

The accounts of TYNEMOUTH ELECTRICITY Department for the year ended March 31, 1921, have only recently been issued and show a surplus of £2 895, compared with a loss of £293 on the previous year. The capital expenditure during the year amounted to £23 623, against £5 578 in 1920, bringing the total capital expenditure up to £127 761, less £67 408 repaid. The units sold numbered 7 516 571, an increase of 1 704 687. The total works cost per unit sold was 0·892d. against 0·868d. the previous year.

At LINCOLN City Council meeting last week, Alderman W. S. White (chairman of the Electricity Committee, said the accounts of the ELECTRICITY UNDERTAKING showed a loss on the year's working of £12 833, making, with the deficit of £6 833 brought forward, a total of £19 666. The Ministry of Health had granted permission to spread the repayment of this deficiency over a period of five years. The balance standing to the credit of the depreciation account at the close of the year was £5 166, and in addition works of replacement and renewal to the value of £27 213 had been met by that account.

With regard to the TRAMWAYS UNDERTAKINGS, the year began with a deficiency of £410, and the loss on the year's working was £644, leaving a deficit of £1 054. A reduction of £1 368 in the working expenses was more than counter-balanced by a fall of £1,403 in the revenue.

The gross profit of WORCESTER ELECTRICITY UNDERTAKING for the year ending March 31 last amounted to £13 758. After allowing for interest (£5 845), repayment of capital (£5 418), and income tax (£1 149), there remains a net profit of £1 346, which is carried forward to the appropriation account, bringing the balance up to £5 018 10s. Of this sum a contribution of £1 500 has been made to the relief of rates, leaving £3 185 to be carried forward. In several previous reports, special reference has been made to the desirability of building up an adequate reserve fund. About two years ago the Council approved of this policy, but up to the present no contributions have been made for this purpose, all surpluses being appropriated for the relief of rates. In addition, the accounts have been further burdened by increased charges for rates and taxes. To meet increased demands it has been decided to extend the power station and generating plant at an estimated cost of £53 950. £157 048 of the capital expenditure has been repaid, leaving the outstanding debt at the end of March, £104 176.

The units sold during the year were 4 583 621, compared with 3 663 349 last year; 25 new motors and 27 heating devices of a capacity aggregating 630 H.P. were connected; 3 599 653 units were sold for industrial service, heating and traction; and 742 108 units for lighting and domestic heating, compared with 589 204 units last year.

The annual report of LIVERPOOL CORPORATION TRAMWAYS Undertaking for 1921 shows a decrease of 47 989 531 passengers carried compared with 1920, but an increase of £105 006 in the receipts. The average earnings per car mile amounted to 27·48d. against 22·82d., or an increase of 4·66d. The gross profit was £258 122. Interest, however, required £54 787, and sinking fund and repayment of loans £46,650, leaving a surplus of £156 685. The sum of £205 261 was spent on renewals. The reserve, renewal and depreciation fund was practically exhausted at the end of 1920 so that the whole of the surplus (£156 685), together with an additional sum of £48 576, was spent on renewals. This latter amount has been carried forward to next year's accounts. The committee approved of the introduction of an improved type of car designed by the general manager (Mr. P. Priestley), and certain new cars of this type were placed in service, and 16 of the older type were re-built and re-modelled. Progress was made in the installation of the new type of route indicator boxes and side screens. Some of the old motor equipments, which were in the works, were converted into an electric welding plant, and the saving effected by being able to carry out repairs with this plant instead of buying new material considerably lessened the cost of repairs and maintenance.

Imperial Notes.

Electricity supply was commenced in BELGRAVE (Victoria) early in April from a power house at Upwey.

The Corporation of JOHANNESBURG have decided to spend £35 000 on extensions of the electric supply mains to the suburbs.

The Municipal Council of SALISBURY (South Africa) recently raised a loan of £70 000, of which £30 000 is to be expended on electricity generating plant.

The Provincial Government of QUEBEC have now decided to, enforce an Act passed in 1921, and commonly known as the "Electricity Licensing and Inspection Act," for the licensing of electricians, for the inspection of wiring installations in public buildings, etc. At first it is proposed to enforce it in Montreal, Quebec and a few of the larger towns.

According to the Toronto correspondent of "The Times" agreements have been completed for the purchase of the radial railways and electric power companies by the Province of ONTARIO and the city of TORONTO, which will require Toronto to assume obligations amounting to $30 000 000 (£6 000 000) and the Provincial Government $18 000 000 (£3 600 000).

A correspondent of the "Times Trade Supplement" states that reports are current that the Government of Ceylon are going to raise fifteen million rupees to start work in connection with a HYDRO-ELECTRIC SCHEME and other important public works, by imposing the Indian Tariff Scale. This will mean a large increase on the existing Customs tariff. It is also stated that preparations are being made to raise another loan in London shortly to finance the hydro-electric scheme as a whole.

The Dominion Steel Corporation has recently been organised for the manufacture of ALLOY STEEL IN CANADA. Works are to be erected at Sarnia (Ontario), and the plant will contain two 75-ton open hearth furnaces, together with two electric furnaces (one 20-ton and one 6-ton), rolling, blooming and sheet mills, etc. The capacity of the works will be 100 000 tons of alloy steel a year, and the initial demand for power, to be supplied by the Hydro-Electric Commission, will be about 15 000 H.P.

A deputation from the KURANDA (Queensland) Progress Association recently received an assurance from the Home Secretary that he would give all the assistance in his power to the scheme for utilising the Barron Falls in the generation of electrical energy. The State Government have agreed to support the scheme provided a load (apart from the Cairns lighting) sufficient to justify the expense can be relied upon. A committee has been formed to endeavour to secure the establishment of power-using industries in the district.

The Johannesburg correspondent of the "Financial Times" states that Mr. Bernard Price, chief engineer in South Africa of the VICTORIA FALLS AND TRANSVAAL POWER CO., in the course of his evidence before the Rand Mining Board, said that the unions seemed under the impression that by the company's refusal to meet them in conference they had been unfairly treated. His view was that when it was impossible to acquiesce in a request it was insincere and useless to engage in a conference. Shareholders in the company had been paid out of reserve funds ever since the establishment of improved conditions after the strike. Certain men had not been reinstated because the company recognised that it was better without them. Such action did not constitute victimisation. He did not agree that it was incumbent upon the companies to re-engage everybody. The machinery created for the purpose of securing the settlement of disputes had been rendered valueless by the extreme action of certain sections, who were always active. His company had been compelled to sell current at the fixed rate prevailing in 1914, being unable to pass the increased charges on to the consumers.

Mr. Forbes Mackay, general manager of the SYDNEY (N.S.W.) Electrical Department, who, returned recently from a visit to Great Britain and Europe, has submitted his report to the Municipality. The report deals with boiler pressures, stokers, ash handling, pulverised coual, ad the automatic protection on the h.t. distributing system. Mr. Mackay thinks it is not desirable in the case of Sydney to go beyond a gauge pressure of 350 lb. to the square inch. With this pressure, and a steam temperature of about 700 degrees F., the steam consumption of turbo-alternators could be brought down to slightly over 11 lb. per kWh. The reduction which might be obtained by going as high as 450 lb. or 500 lb. to the square inch would not justify the extra first cost and probable extra cost of maintenance of boilers, pipework, etc. Provided prices quoted were suitable, the Council should consider the installation of retort automatic stokers. The best method of dealing with ashes which he had seen was that of allowing the ashes to fall continuously from the back of the grate into a trough kept automatically full of water, in which trough there was travelling under the water an endless chain conveyor. The use of pulverised coal under the boilers should not be adopted yet. It is not advisable to provide full automatic differential protection for the whole high tension distributing system. Under Sydney conditions of high temperature of circulating water and therefore comparatively low vacuum, there is no reason why a turbo-alternator to run at 3 000 revs. per min., and rated at from 14 to 16 000 kW, should not be ordered. The armour-clad type of switchgear would be better for Sydney Council's purpose if it was decided to establish a new power house. At present the use of the mercury arc rectifier was not advisable.

Foreign Notes.

From June 17 to June 26 an INDUSTRIAL GOODS FAIR will be arranged by the BUDAPEST Chambers of Commerce and Industry.

The first 100 000 V transmission system in AMERICA dates from the year 1909, and since then about 20 electric supply companies in the UNITED STATES have adopted a transmission voltage of 100 000 or over. Four companies use 100 000 V, two 102 000 V, two 104 000 V, and seven 110 000 V lines, the remainder employing 120 000 to 150 000 V. On the Pacific coast one company is making preparations to introduce 220 000 V in a portion of its area.

The "Times" correspondent at Cairo states that the RUTENBERG CONCESSION has caused considerable indignation in Palestinian and Syrian circles there. The opinion, he says, is freely expressed that the concession, if allowed to stand, would give Mr. Rutenberg and his backers a position of control which would be intolerable; and the Government of Palestine is blamed for its action, which is regarded as being in every respect an abuse of the mandatory powers.

Mr. W. F. Vaughan Scott, who has been Commercial Secretary to H.M. Legation in Santiago, Chile, is in the United Kingdom pending transfer to another post, and will be in attendance at the Department of Overseas Trade (35, Old Queen Street, S.W.1) until June 24. He can be interviewed by firms interested in TRADE WITH CHILE, and he will also (if desired) furnish information concerning trade with Bolivia. After the 24th inst. Mr. Vaughan Scott will visit important industrial centres in the provinces. Applications for interviews should be addressed to the Department (reference 3808/TG/GP).

H.M. Consul-General at New York (Mr. H. Gloster Armstrong) has written to the Department of Overseas Trade calling attention to the facilities now available to representatives of U.K. firms visiting NEW YORK, at the offices of the British Empire Chamber of Commerce (Cunard Building, 25, Broadway). The Chamber has arranged for the formation of a sample room where British commercial travellers can, for a moderate charge, exhibit their goods, take orders, obtain office facilities and clerical assistance, and generally make it their headquarters during their stay in New York. Firms requiring the use of the sample room for their representatives should communicate with the Chamber well in advance. Further particulars can be obtained from the secretary.

Institution Notes.

The annual meeting of the ASSOCIATION OF OFFICERS AND STAFF MEMBERS OF ELECTRICITY (POWER AND SUPPLY) COMPANIES OF GREAT BRITAIN will take place at 8 p.m. on Tuesday next, at Caxton Hall, Westminster.

The Swansea meeting of THE INSTITUTE OF METALS will be held on September 20 to 22 next. Swansea is a metallurgical centre of great importance. Those who are desirous of attending the meeting can obtain membership particulars from the Secretary. An election of members will take place on the 13th prox.

At the last meeting of the DIESEL ENGINE USERS' ASSOCIATION Mr. H. F. P. Purday, B.Sc., A.C.G.I., read a paper on "Marine Diesel Engines." He referred to the main points of difference in the design of marine Diesel engines compared with land engines, and after dealing with the principal types of marine Diesel engines the author dealt with the four-stroke and two-stroke engine and referred to opposed piston two-stroke engines using solid injection and air injection of fuel. He discussed the thermal difficulties of large Diesel engines and pointed out that the trend of modern design seemed to be to eliminate extensive temperature stresses by dividing the castings into smaller pieces having considerable freedom from expansion. He favoured the provision of concave crowns to pistons, as the further the centre of the crown was away from the fuel valve the less heat it would presumably receive. He considered that the Diesel engine must be seriously considered in the near future for propelling large ships.

In the ensuing discussion the view was expressed that further development of the marine Diesel engine was likely to follow along the lines of the double acting two-stroke engine. Further interesting information was given concerning the cylinder construction of the "Still" engine.

A.C. House Meters.

A well designed series of watt-hour meters for alternating current domestic circuits has been put on the market by MEASUREMENT, LTD. These are made in two types, for two and three wire single phase circuits respectively. Both meters are manufactured in sizes up to and including 30 A, and are made throughout in accordance with the B.E.S.A. specification. In addition, the makers call attention to the simplicity of their design and their easy accessibility, while another important point is the light weight of the moving element. Electrically the meter follows the usual lines, and an accuracy within 2½ per cent. from 25 per cent. overload to $\frac{1}{10}$th load at any power factor from unity to 0·5 is claimed. These claims are borne out by test curves.

Telephone and Telegraph Notes.

The BELGIAN TELEPHONE SERVICE, which was of course very much disorganised by the war, last year exceeded the number of subscribers (54 700) existing in 1914 by over 4 000.

Mr. J. Milward, the manager in Australia of the Pacific Cable Board, is at present in London in connection with the proposed scheme for the DUPLICATION OF THE PACIFIC CABLE, and a decision is expected in a few days.

An important fusion of telephone interests has been recently arranged between the L.M. Ericsson General Telephone Co. and the H.T. Cedergren General Industrial Company, manufacturers of telephone wires and cables. This amalgamation has been brought about for the purpose of effecting economies and to increase the competitive value of the Swedish telephone industry.

The telephone and telegraph lines connecting LUNGCHINGTSUN with the neighbouring marts of YENKI and TOWTAOKOW, erected last year by the Japanese military authorities, are now being operated by the Japanese post office. A telephone system is to be established in KAIFENG, Honan; the PEKING Telephone Administration will shortly establish a new south office with facilities for 2 000 additional subscribers. The equipment is being obtained from America.

According to a return which has been prepared for the Postmaster-General, during April last the number of telegrams which passed through the Central Telegraph Office was 3 600 000, the highest figure since July, 1921, when 3 625 143 messages were dealt with, and 660 000 more than in April, 1921. The instances of complaints of delay from all causes during April, 1922, were only eight. The number of telegrams received from subscribers to the telephone system during the financial year was 785 622, an increase of 49 859 over the corresponding period of 1920–21. The number of telegrams delivered by telephone was 663 754, or 2 per cent. less than in the previous year. The number of telegrams which passed through the cable room of the Central Telegraph Office was 9 324 825, as compared with 9 408 297 in 1920–21. This small variation is regarded as not unsatisfactory in view of the trade depression which affects Europe generally. Direct wires are now worked from the London Stock Exchange to Paris and Amsterdam, and have fully justified themselves. There was an increase of 11 per cent., or 1 116 218 words, in the traffic sent by the Imperial Cable, the respective figures for 1920–21 and 1921–22 being 9 885 640 and 10 999 858.

Wireless Notes.

A reduction from 4½d. to 4d. a word is announced in the rate for DEFERRED WIRELESS MESSAGES via Marconi from Great Britain to the Eastern zone of Canada.

The BELGIAN merchant service, which before the war included ten wireless units, now possesses more than 120, which are controlled by the Administration des Télégraphes.

Messrs. Cross Bros., Ltd., have installed a WIRELESS RECEIVING STATION at their premises in St. Mary Street, Cardiff, engaged a wireless engineer and announce daily demonstrations to which the public are invited.

The Central Telegraph Office is now carrying on wireless services to Berlin, Cologne, Posen, Rome, and Egypt. News handed in at that office is broadcasted from the Post Office wireless station at Leafield, near Oxford, and is picked up in India and Australia, except when atmospheric conditions are unfavourable; while a regular wireless news service is carried on with Halifax, Canada.

In his report for 1921 on the economic, commercial and industrial situation of SWEDEN, Mr. H. Kershaw H.M. Commercial Secretary at Stockholm, states that serious attention is being paid to the possibilities of the practical use of the wireless telephone, and during the summer exhibition in Lulea wireless telephone communication was carried on largely between that city and Boden. Experiments were also carried out during the early part of the year with the object of examining the possibilities of the use of high frequency power cables.

Personal and Appointments.

The Albert Medal of the Society of Arts for 1922 has been awarded to SIR DUGALD CLERK, K.B.E., for his important contributions to the development of the internal combustion engine

The marriage took place on June 1, at St. Paul's Church, Halifax, of Mr. Eric N. Johnson, A.M.I.E.E., elder son of Mr. S. C. Johnson, of Manchester, and Miss Lena Barnes, third daughter of Mr. F. J. Barnes, of Luddenden Foot.

The ENGAGEMENT is announced between Norman Felix Herbert Freudenthal, late Grenadier Guards, only son of Mr. and Mrs. J. Freudenthal, Eton Avenue, London, N.W., and Iris Hilda, elder daughter of Mr. and Mrs. M. J. Railing, of "Whiteknights," Reading, and Duke Street, W.

MR. J. H. TAYLOR, assistant engineer, Central Argentine Railway, has been awarded the "George Stephenson" Gold Medal of the Institution of Civil Engineers for his paper on "The Application of Electric Traction to the Suburban Lines of the Central Argentine Railway." Mr. Taylor is also a Miller Prizeman of the Institution.

Miscellaneous.

Cambridge University have gratefully accepted the offer of Sir Ernest Moir, Bt., to endow a PRIZE IN THE ENGINEERING DEPARTMENT in memory of his son Reginald, an engineering student, who was killed in the war.

A Berlin special message to the "Temps" says that following the example of Herr Hugo Stinnes, his rival, DR. RATHENAU, is buying up big industrial concerns in Austria, and has just acquired the large establishments of Woellersdorf.

The 12-cylinder Sunbeam Racer, on which Mr. K. Lee-Guinness surpassed many previous WORLD'S RECORDS AT BROOKLANDS on May 17 and 20, was equipped with B.T.-H. magnetos. A B.T.-H. magneto was also fitted to the Triumph machine on which Mr. W. W. Brandish secured second place in the Senior T.T. race.

We regret that in the Editorial Notes referring to Mr. Mitchell's paper in last week's issue we said that the COAL CONSUMPTION AT THE DALMARNOCK GENERATING STATION was 10.65 lbs. per unit generated. This, of course, should be the steam consumption, the coal consumption given by Mr. Mitchell being 1.98 lbs. per unit delivered.

The result of the ENGINEERS' BALLOT is a majority of 36 000 (nearly two to one) in favour of returning to work at once. Only about one-third of the members voted. The lock-out, which has now been lifted, occurred on March 11. Arrangements have been made for resuming work at once, and some returned on Wednesday. As the Foundry Workers' Union have also accepted the masters' terms, only the Boilermakers remain to be settled with.

During the year 1921 there were 35 132 APPLICATIONS FOR PATENTS, or 1 540 fewer than in 1920, and the complete specifications filed numbered 19 159, (2 637.). The applications from women inventors were 297 (against 311) and those made by way of communication from abroad 1 339 (compared with 1 265). The total receipts were £525 500 (against £487 542), including £445 947 from patent fees, £9 648 from designs, and £47 803 from trade marks fees.

The new WHITE STAR LINER "PITTSBURGH," is interesting because she is propelled by steam generated by oil fuel, but apart from that nearly every other service on the ship is performed by electricity. The electric generating plant is capable of supplying over 1 000 h.p., and upwards of 80 miles of electric cable are used. The steering is by the Wilson-Pirrie electric gear, the boats are lowered electrically; there are seventeen electric winches for cargo handling; the lifts, sounding machines, printing press, bilge pumps, etc., are all operated by electricity. Moreover, the "Pittsburgh" has a very complete electric cooking outfit. Mr. W. J. Willett Bruce, superintendent engineer of the White Star Line, is making the voyage for the purpose of observing the way in which the electrical installation operates.

Business Items, etc.

Mr. W. M. Selvey, consulting engineer, of Sheffield, is opening a London office at 23, Old Queen Street, Westminster, S.W.1, and from July 1 he will reside in London.

An agreement has been concluded between the MINERALS SEPARATION, LTD., of London, and the Electro-Osmose Aktien-Gesellschaft, of Berlin, which includes a mutual exchange of patents.

Messrs. Owen & Palmer have taken over the business of Messrs. H. D. Carter, Ltd. (Bangor), carried on at Faraday House, High Street, Bangor. Mr. Owen was manager for Messrs. Carter and Mr. Palmer has been with Vickers, Ltd., and the General Electric Co.

The board of the INDUSTRIAL PUBLICITY SERVICE has been reconstituted and the following have been appointed directors: W. Rutherford (Chairman), Major J. Proctor Humphris (appointed by the F.B.I.), T. C. Elder (appointed by the B.E.A.M.A.), R. H. W. Hope, M.C. (C.M.A.), and C. J. de B. Sheringham, D.S.O., M.C. (British Engineers' Association).

The SOCIÉTÉ ANONYME FAMA, of Paris, has the exclusive licence under the Riley patents to construct and instal Riley stokers for Great Britain and its Dominions, as well as for France, and a British company will shortly be formed, but meanwhile inquiries for the stokers should be addressed to 64, Mark Lane, London, E.C.3. The company has recently installed the stokers at the Gennevilliers power station of the Union d'Electricité, Paris.

Catalogues, Price Lists, &c.

The monthly magazine and price list of HIGGS BROTHERS for June is, as usual, full of both entertaining and useful information.

The June price list of motors and dynamos manufactured by the A.C.E.C. (ATELIERS DE CONSTRUCTIONS ELECTRIQUES DE CHARLEROI) is to hand.

The SWEDISH GENERAL ELECTRIC, LTD., have issued the following new stock lists:—No. 42 F, single-phase a.c. fans; No. 111 d.c. "K" motors, and s.p. Century motors; No. 111a, 3-phase and 2-phase motors, s.p. commutator motors, transformers, etc.

An illustrated leaflet (Supplement 1 to Catalogue 600) is to hand from SIEMENS BROTHERS AND CO., and contains detailed information regarding the primary cells and batteries (dry and fluid) manufactured by the firm for the h.t. circuit of wireless apparatus using thermionic valves.

Tenders Invited and Accepted.

UNITED KINGDOM.

BRIGHTON Guardians. June 20.—Electrical fittings, etc. Tender forms from the Clerk, Mr. H. Burfield, Prince's Street.

WEST DERBY (LIVERPOOL) Guardians. June 20.—Electric lamps. Tender forms from the Clerk, Mr. H. P. Cleaver, Brougham Terrace, Liverpool.

WARRINGTON Guardians. June 20.—Electrical goods for three months. Tender forms from the Clerk, Mr. A. Bottomley, Bewsey Chambers.

SALFORD CORPORATION, July 3.—E.h.t. and l.t. switchgear and transformers. Specifications from Borough Electrical Engineer (Frederick Road), and tenders to Town Clerk, Town Hall, Salford.

KIRKCALDY CORPORATION.—July 10.—Converting plant specifications from Kennedy and Donkin, consulting engineers, 17, Victoria Street, Westminster, S.W.1.

INDIA.

EAST INDIAN RAILWAY. June 21.—Electric overhead travelling cranes. Tenders to the secretary of the company, 28/30, Nicholas Lane, London, E.C.4. Particulars from the Department of Overseas Trade.

EAST INDIAN RAILWAY Co., June 21.—Electric overhead travelling crane. Specification at company's offices, 28-30, Nicholas Lane, London, E.C.

SOUTH AFRICA.

MUNICIPALITY OF ROBERTSON. August 14*.—Supply, delivery and erection (optional) of *two 75 kW steam sets and equipment for power station (Contract No. 1); one 300 A.h. battery (Contract No. 2); material for the outside distribution system (Contract No. 3).

CHILE.

CHILEAN STATE RAILWAYS. July 11.—Structural steel for repairing bridges; insulated copper cable for welding purposes, 440 V.

CANTERBURY City Council has accepted the tender of Meldrum, Ltd., for a dust destructor at £1 395.

BRAY (Co. Wicklow) Urban Council have accepted the tender of Mirrlees, Bickerton and Day for a Diesel engine and alternator at £5 233.

YORK Corporation have accepted the tender of the British Thomson-Houston Co. for a rotary converter, switchgear, etc., at £2 753.

BLACKPOOL Gas Committee have accepted the tender of Mr. Thomas Barton for the supply of electricity controlling gear at the gas works.

BARROW Corporation have accepted the tender of Johnson and Phillips for e.h.t. and h.t. transmission lines to Rampside and Roa Island at £2 816 3s. 7d.

NAVAN Council have accepted the tenders of Hay, Maryon and Co. for turbines, at £2 983, plus £280 for erection; and British Mannesmann Tube Co. for 120 poles, £616.

HALIFAX Corporation are recommended to accept the tenders of the British Thomson-Houston Co. for feeder equipment and control panel, £945; and A. Reynolle and Co. for nine e.h.t. switch panels, £3 100.

LIVERPOOL Corporation have been recommended to accept the tender of R. Dempster and Sons for ash conveyor and accessories and coal-handling plant at Lister Drive, No. 2 power station; British Insulated and Helsby Cables, for 33 000 V main; and A. E. and T. H. Chesters for wiring 24 houses.

STEPNEY Borough Council have accepted the following tenders:—RANSOMES AND NAPIER (lowest tender received), a 50-ton electrically driven overhead travelling crane at Limehouse generating station; the provision of spare parts and accessories and the dismantling of the existing 20-ton hand-operated crane and its re-erection at Mile End sub-station, £3 455. Eighteen tenders were received, the highest being that of Isles, Ltd., £6 200. PERRY AND CO. (BOW), LTD., circulating water pipes at Limehouse, £2 134; GENERAL ELECTRIC CO., three motor converters, £10 114; E. AND F. WRIGHT, cast iron pavement boxes, frames and covers, £60 6s. 7d.; SUTTON AND CO. (OVERSEAL), LTD., troughs and covers, £452 9s. 8d.

The MADRAS GOVERNMENT have ordered from the Marconi Co. seven sets of wireless apparatus for erection in the MOPLAH country. One will be set up at the headquarters at Malapuram, and the others at the various auxiliary police posts.

H.M. Chargé d'Affaires at Havana has prepared a report on the market for wire and wire products in CUBA, which can be seen at the Department of Overseas Trade. A recent catalogue of an American wire company, who have secured a large proportion of the Cuban trade in wire and wire products, can also be inspected at the Department, as well as samples of certain goods referred to in the report.

Companies' Meetings, Reports, etc.

Great Northern Telegraph Company.

The report of the directors for the year 1921 states that the company succeeded in repairing two of the three cables (one Anglo-Danish and one Franco-Danish) which were difficult to repair on account of mines, but it has not yet been possible to repair the Petrograd-Libau cable. The Russian Government is, however, taking the necessary steps to clear the mines from the area where the cable is broken, and there are, consequently, good prospects of the cable being repaired this summer. Besides these repairs, the company has had to deal with 21 interruptions on 8 cables in Europe, and 12 interruptions on 5 cables in the Far East. The c.s. "H. C. Orsted" has been occupied in European waters for 253 days, of which 12 have been for the account of other administrations, whilst in the Far East the "Store Nordiske" and "Pacific" have been in commission for 191 days, including 120 days on charter by other administrations.

Communication with the Far East.

Both the Russian Government and the company have done everything in their power to re-establish telegraphic communication between Europe and the Far East *via* Siberia. Whilst the lines through Russia and Siberia are maintained in good condition by the Russian Government, it is impossible to establish communication between the Russian telegraph system and the cables and landlines in the Far East, either *via* Wladiwostock or *via* Kiachta, owing to the total interruption of both routes. The restoration of the Wladiwostock route is hindered by the state of war between the Governments of Tchita and Wladiwostock, whilst the restoration of the Kiachta route is dependent upon the Governments of Peking and Urga succeeding in arriving at an agreement. Under the circumstances, the company has had to fall back upon another scheme which became possible of realisation, thanks to the facilities granted by the Russian and Chinese Governments, resulting in the establishment of a quite new route by means of a wire placed at the exclusive disposal of the company by the two administrations between Irkutsk and Peking, *via* Blagowestschensk—Helampo—Harbin, and worked in connection with the company's direct wire between Petrograd and Irkutsk. A repeater station, equipped by the company and manned by Danish operators, has been established at Harbin. Communication was thus re-established on March 26 last after an interruption of nearly four years.

The company's negotiations with Russia, mentioned in last year's report, have been brought to a successful issue, and in the course of the summer an agreement, covering a long term of years, was signed whereby the company is enabled to renew its former activities in Russia. Although the preparations for reopening the company's telegraph office at Petrograd proved very difficult, as well as long and costly, the company was, nevertheless, able to re-establish telegraphic communication with Petrograd on January 18, 1922. The concession granted by the Government binds the company to open a telegraph station at Moscow, thereby placing the Russian capital in direct telegraphic communication with the company's European system. Various causes have, however, hitherto prevented the carrying into effect of this undertaking. The Russian terminal traffic exchanged with Western Europe and America is, so far, quite inconsiderable compared with the corresponding traffic in pre-war times.

Concessions and Year's Working.

Negotiations with England and Sweden in connection with a prolongation of the company's concessions have been carried on during the year, but have not yet been brought to a final conclusion. Preliminary discussions with the Chinese Government were commenced last year by the company, in conjunction with the Eastern Extension Australasia and China Telegraph Co., with the object of obtaining a prolongation of the existing agreements between China and the two companies. Owing, however, to the decision come to by the International Conference in Washington to include the question of telegraph communication in China amongst the items for discussion there, it became necessary to suspend temporarily the companies' own negotiations in Peking. A new cable steamer destined to replace the "Store Nordiske" is being built at a Danish shipyard. The company's new building at Shanghai and the dwellings for the staff at Peking were completed during the year. The directors record with regret the death of the honorary Chairman (Commodore E. Suenson), for so long associated with the company.

In spite of the fact that the net profit is about 32 per cent. less than the previous year, and that the traffic as a whole does not as yet show any tendency to increase, the directors consider themselves justified in recommending a total dividend and bonus of 22 per cent., a decrease of only 2 per cent. compared with last year. The reserve fund will be credited with the usual amount (£33 333), whilst it is proposed to contribute £55 555 to the pension fund of the staff, and to carry forward about the same amount as the previous year. The traffic receipts, etc., are about £533 670 less than the previous year, mainly due to the loss on exchange showing a drop of about £395 700. The decrease in traffic receipts is partly counterbalanced by a reduction under expenditure of about £331 625. The latter decrease is mainly accounted for by only £116 980 having been taken to meet the payment of taxes, against £416 666. The actual working expenses show a decrease of about £32 000 only.

Aluminium Corporation.

Addressing the shareholders at the annual meeting of the Aluminium Corporation, Ltd., last week, Mr. Kenneth M. Clark (the chairman), who presided, said that the accounts submitted covered a period of two years. The gross profit for the two years amounted to £87 434, or an average of just over £43 000 per annum. The net balance of profit and loss account, after paying the preference dividend for 1920, amounted to £25 150, and this enabled the directors to recommend payment of the 7 per cent. preference dividend for the past year, leaving a balance of £13 261 10s. to be carried forward to next year's accounts. A sum of £321 421 had been expended during the past two years on constructional work. The depreciation reserve now amounted to £26 000. Shares and loans in subsidiary companies stood at £102 957. Stocks of metal, raw material, etc., showed an increase of £43 775, which was not abnormal, and sundry debtors were up about £27 000. Cash at bank and in hand amounted to £7 443. The accounts did not include any returns from the very heavy expenditure incurred during the last five years in the construction of the dams at Cowlyd and Llugwy.

The great difficulty in the development of water power was the time required to make the necessary reservoirs and to negotiate the various rights. He was glad to say that the whole rights had now been acquired; the dams had been completed, and the work of constructing the canal connecting the two lakes was in active progress, and should be completed within three months. Once this was carried through they would have a greatly increased supply of electrical energy at their disposal, both for the supply to the power company and for the manufacture of aluminium. During the whole period of depression they had been able to obtain sufficient orders to keep the rolling mill in continuous operation. An extraordinary general meeting of the company had been called to follow this meeting for the purpose of increasing the directors' borrowing powers. If this resolution was agreed to the directors proposed to increase the capacity of the rolling mill, to instal a second and larger pipe line with pen stock reservoir, and to erect a new power house with the necessary machinery. This would enable them to utilise a considerable amount of water power at present partly developed, and was called for by the business they were able to do in aluminium sheet and by the demands that would be made upon them for energy by the North Wales Power Co.

At the meeting which was afterwards held, the directors were empowered to borrow for the purposes of the company (in addition to the amount authorised by clause 83 of the articles of association, and the extraordinary resolution passed December 13, 1920) sums not exceeding in the aggregate £500 000.

The directors of the Electrical Apparatus Co., Ltd., invite applications for 50 000 8 per cent. cumulative preference shares at par. The lists close on or before the 17th inst.

A petition for confirming the proposed reduction of the capital of the British Power Railway Signal Co., Ltd., and reduced from £50 000 to £25 000, will be heard by Mr. Justice Astbury on June 27.

The net profit of Doulton and Co. for 1921, after providing for depreciation, was £75 568, making available with £54 251 brought forward £129 820. A dividend of 5 per cent. has been declared, carrying £53 243 forward.

The transfer books of the Automatic Telephone Manufacturing Company will be closed from the 17th to the 24th inst. for preparing the dividend warrants on the preference shares for the half-year ending the 30th inst., when the warrants will be posted.

The directors of the Yorkshire (West Riding) Electric Tramways Company have decided to pay on July 1 an interim dividend of 3 per cent. (being at rate of 6 per cent. per annum) on the 6 per cent. cumulative preference shares for the half-year ending June 30.

The net profit of the British Electric Traction Co. for the past year amounted to £218 494, plus £177 319 brought forward. A dividend on the ordinary shares of 4 per cent. is proposed, placing £14 677 to reserve, and carrying forward £194 238, subject to corporation tax for three years.

The Stock Exchange have allowed dealings in £94 200 6½ per cent. cumulative "A" preference, and £177 100 7½ per cent. cumulative "B" preference shares of the General Electric Co. This represents the whole of the unissued balance of the "A" and "B" preference capital.

At the annual meeting of the Penarth Electric Lighting Company last week, the chairman, Mr. Geo. J. Somerville, presided. The report and the accounts were adopted, and dividends of 7 per cent. on the preference shares and of 7½ per cent. on the ordinary shares were agreed to, leaving £2 532 17s. 7d. to be carried forward.

At the ordinary general meeting of the Merthyr Electric Traction and Lighting Company on the 8th inst., it was reported that the available balance for the past year was £6 432. A sum of £1 200 was placed to reserve, and dividends of five per cent. on the preference and six per cent. on the ordinary shares were declared, £1 332 being carried forward.

The profit of the Chloride Electrical Storage Co. for the year to March 31, 1922, after providing for depreciation and taxation, was £73 968, plus £23 340 brought in. The directors recommend a further dividend of 5 per cent. on the ordinary shares, making 10 per cent. free of tax, placing £20 000 to employees' benefit fund, £20 000 to reserve (making it £60 000), carrying forward £31 613.

The directors of the Brazilian Traction Light and Power Company have decided that, although the exchange value of the milreis continues considerably lower than was generally anticipated, there are clear indications of such improvement in general conditions as to justify the resumption of the payment of dividends on the ordinary shares. The Board have accordingly declared a dividend of 1 per cent. on the ordinary capital, payable September 1 next. The last ordinary dividend was paid in 1917.

The net receipts of the Pernambuco Tramways and Power Co. for 1921 totalled £69 731, plus £18 373 brought in. After providing for interest, reserve, amortisation fund, etc., £1 107 remains to be carried forward. The directors regret it was not possible to pay any dividend on the preference or ordinary shares. The reduction in the net revenue was entirely due to the fall in Brazilian exchange. If exchange had remained the same as in the preceding year, net results would have shown an improvement over the previous year.

The accounts of Ransomes, Sims and Jefferies (associated with Ruston and Hornsby) for the year ended March 31, 1922, after making provision for depreciation and bad and doubtful debts, more particularly those debts affected by the war, also after deducting interest on debenture stock and deposits, show profit of £3 997, against £15 457 for the previous year. The dividend on the preference shares to June 30, 1921, absorbs £2 750, leaving with £40 811 brought forward, £42 058. Owing to the continued adverse trade conditions the fall in selling values and the necessity for conserving the resources, the directors regret that they are unable to recommend any dividend on the ordinary shares for the year or on the preference shares for the half-year to December 31, 1921.

The report of Ruston and Hornsby, Ltd., for the year ended March 31 last shows a balance on profit and loss account of £101 637, which, after allowing for depreciation £55 952, and interest on debentures £25 500, leaves a balance of £20 185. This, with the balance from last year of £43 920, makes a total of £64 105, from which is deducted the preference dividend paid last July, leaving a net balance of £58 230. The directors "regret that owing to the continued trade depression and the serious fall in stock values, it is essential that the whole of the above balance should be retained in the business, and in addition they thought it wise to transfer £100 000 from the general reserve to meet a possible further fall in the values of stock-in-trade. Under the circumstances they do not recommend the payment of the outstanding dividend on the preference shares, or a dividend on the ordinary shares for the past year." For the year ended March 31, 1921, there was a profit of £108 683, but no ordinary dividend was paid. For the previous year 5 per cent. was paid on a profit of £165 397.

The gross earnings of the United River Plate Telephone Company for the year 1921 were £1 161 848, and the maintenance and other charges in Argentina and London were £981 411, leaving a profit of £180 438. Deducting interest on debenture stock, dividend on preference shares to December 31, 1921, and the interim dividend on the ordinary shares (£72 100), and adding amount brought forward (£38 367), the available balance is £146 705. The directors recommend payment of a final dividend of 5 per cent. on 324 000 ordinary shares, making, with the interim dividend, a total of 8 per cent. for the year, tax free (£81 000), and a dividend of 5 per cent. on 108 000 ordinary shares, tax free (£27 000), the balance to be carried forward being £38 705. Progress has been made during the past year, but although a record number of subscribers have been connected, many thousands of applicants are still awaiting service. The automatic plant in course of erection will relieve the position somewhat, but it is hoped the Government will shortly realise that the large amount of capital needed to meet the additional telephonic requirements of the country cannot be raised until the increase in the tariffs petitioned for in 1919 is granted.

The net revenue of the Globe Telegraph and Trust Company for the year ended May 31, after deduction of expenses, amounts to £330 146, and, with £2 181 brought forward, the total is £332 327. From this amount £233 605 has been distributed in interim dividends, leaving £98 722. The directors now recommend payment of the following final dividends—viz., 3s. per share (less tax) on the preference shares, making, with previous distributions, a total dividend for the year on those shares at rate of 6 per cent. per annum (less tax); and 5s. per share net on the ordinary shares, making, with previous distributions, a total dividend on those shares at rate of 10 per cent. net for the year. These dividends will absorb £77 868, leaving £20 853 14s. 8d. to be carried forward. During the year under review fifty-three certificates of the Submarine Cables Trust belonging to the Globe Company were drawn and paid off at £120 per certificate. The proceeds have been reinvested in Eastern Telegraph Company's ordinary stock and Eastern Extension and Western Telegraph Companies' shares. The articles of association, which date back to the incorporation of the company in 1873, are now out of print, and, as they are in many respects obsolete, new articles will be submitted for approval at an extraordinary general meeting which will be held after the annual meeting.

New Companies.

Commercial Engineering Co.

COMMERCIAL ENGINEERING CO., LTD. (182 117.)—Private company. Reg. May 29. Capital, £2 000 in £1 shares. Electrical, automobile and general engineers, etc. Subscribers: J. McNaughton and F. C. Farthing. Solicitors: Nash, Field and Co., 12, Queen Street, Cheapside, E.C.

Summit Electrical Co.

SUMMIT ELECTRICAL CO., LTD. (182 383).—Private company. Reg. June 9. Capital, £100 in £1 shares. Electrical engineers, manufacturers of, dealers in and agents for all kinds of general electrical supplies, motor cars and parts, etc. Reg. office: 11, Bucknall Street, Bloomsbury, W.C.2.

John M. Boyd.

JOHN M. BOYD, LTD. (12 249).—Private company. Reg. in Edinburgh June 6. Capital, £5 000 in £1 shares. General, electrical, and motor engineers, etc. Directors are: J. M. Boyd and J. B. Andrews. Secretary: David R. Galloway. Reg. office: Ballochmill Road, Eastfield, Rutherglen.

Ledger Taylor & Co.

LEDGER TAYLOR AND CO., LTD. (182 263.)—Private company. Reg. June 2. Capital, £3 000 in £1 shares. Electrical, hydraulic engineers and contractors, etc. First directors: R. W. Taylor and Mary J. Taylor. Secretary: F. Boothby. Reg. office: Moorgate Ironworks, Moorgate, East Retford.

Building and Insulating Material Co.

BUILDING AND INSULATING MATERIAL CO., LTD. (182 210.) Private company. Reg. June 1. Capital, £5 000 in £1 shares. Builders and contractors, etc., electrical engineers and contractors, suppliers of electricity. Subscribers: S. G. Robinson and O. V. Monk. Reg. office: 20, Essex Street, Strand, W.C.

Arco Institute, Ltd.

ARCO INSTITUTE, LTD.—(182 285.)—Private company. Reg. June 6. Capital, £100 in £1 shares. To adopt an agreement with A. Rosenberg and to carry on the business of electro-therapy, electro-medical treatment, etc. Directors are: H. J. Munro and A. Rosenberg. Reg. office, 3, London Wall Buildings, E.C.2.

Abrey and Gerratt.

ABREY AND GERRATT, LTD. (182 355).—Private company. Reg. June 8. Capital, £2 000 in £1 shares. Mechanical, electrical heating and ventilating engineers, contractors, manufacturers, sheet metal workers, exporters, etc. Permanent directors are: H. S. Abrey and W. Gerratt. Reg. office: Wexham Road, Slough, Bucks.

World's Electric Co.

WORLD'S ELECTRIC CO., LTD. (182 283.)—Private company. Reg. June 2. Capital, £1 000 in 1s. shares. Manufacturers of and dealers in electrical accessories, appliances, lamps, apparatus, plant and machinery, contractors, etc. First directors: A. Richmond, J. W. Conrad and W. F. Pearce. Reg. office: 1, Gresham Buildings, E.C.2.

Johnson Radio Co.

JOHNSON RADIO CO., LTD. (182 326).—Private company. Reg. June 7. Capital, £100 in £1 shares. Engineers, manufacturers of and dealers in ordinary and wireless telegraphic and telephonic apparatus and accessories, electrical apparatus, etc. Directors are: H. M. Smith and S. Tootill. Secretary (*pro tem*): H. G. Goodsman. Reg. office: 244, Tottenham Court Road, W.C.

V. P. & G. Hastings.

V. P. AND G. HASTINGS, LTD. (182 307.)—Private company Reg. June 6. Capital, £5 000 in £1 shares. Engineers, manufacturers of machinery, tool makers, founders, metal workers, electrical engineers, manufacturers of and dealers in automobiles, etc. Permanent directors are: V. P. Hastings and G. S. Hastings, Reg. office, Duchy Chambers, Clarence Street, Manchester.

New Electric Sign Co.

NEW ELECTRIC SIGN CO., LTD. (182 266.)—Private company. Reg. June 2. Capital, £2 500 in £1 shares (1 000 preference). To take over the business of an electric sign manufacturer and agent carried on by A. E. Davis as the "New Electric Sign Co.," at 53, Haymarket, S.W. First directors: A. E. Davis and J. H. Slingsby. Secretary: S. H. Grant. Reg. office: 53, Haymarket, Westminster, S.W.

W. Blackburn (Kew).

W. BLACKBURN (KEW), LTD. (182 280.)—Private company. Reg. June 2. Capital, £1 000 in £1 shares (800 8 per cent. cumulative preference). Electrical, mechanical, motor, and general engineers and contractors, manufacturers of and dealers in transformers, radiators, dynamos, motors, and all kinds of electric lighting, power and transmission plant, etc. Solicitors: T. E. Godbold, 529, High Road, Chiswick, W.4.

Chimes, Ltd.

CHIMES, LTD. (182 289).—Private company. Reg. June 6. Capital, £500 in £1 shares (400 "A" ordinary and 100 "B" ordinary). To adopt agreement with W. A. Greening, W. A. Rowe, and W. E. Schall and to develop and turn to account patent No. 171 835 for the manufacture of apparatus for the electrical chiming of church bells. Permanent directors are: W. E. Schall and W. A. Greening. Secretary, E. Dunkel. Reg. office, 71–75, New Cavendish Street, W.

Radio Instruments.

RADIO INSTRUMENTS, LTD. (182 272.)—Private company. Reg. June 2. Capital, £10 000 in 7 500 8 per cent. cumulative preference shares of £1 each and 50 000 ordinary shares of 1s. each. Electrical, mechanical and general engineers and contractors, manufacturers and sellers of transformers, radiators, dynamos, motors and radio instruments of all kinds, and electric lighting power and transmission plant and wireless apparatus, etc. Permanent directors: J. Joseph and W. A. Appleton. Reg. office: 18A, Hyde Street, Oxford Street, W.

A. Adams & Co.

A. ADAMS AND CO., LTD. (182 208.)—Private company. Reg. June 1. Capital, £9 000 in £1 shares. To acquire the business, and all or any of the assets and liabilities in connection therewith, carried on by B. Foulkes Winks at 24, Charing Cross Road, W.C., as Adams and Co., and to adopt agreements with the said vendor and C. J. Bannister and to carry on the business of manufacturers of electrical and scientific apparatus, and electrical, mechanical or scientific instruments, etc. First directors: B. Foulkes Winks, C. J. Bannister, and Miss M. A. Foulkes Winks. Reg. office: 24, Charing Cross Road, W.C.

The "Falco" Breakfast Cooker.

The "Falco" electric breakfast cooker has just been placed on the market by the FALKIRK IRON COMPANY. It is substantially constructed of fine cast iron, with a bright top table and adjustable strip tin and grid. The inside measurements are 10½ in. wide by 9 in. deep by 5¾ in. high. The top table measures 12½ in. by 10½ in.,

"FALCO" ELECTRIC BREAKFAST COOKER.

and is fitted with a grid covering the grilling element, which also acts as a boiling plate. An asbestos mat is also supplied to lay on the grid when grilling only The cooker is fitted with an easily accessible, open coil heating element protected by a wire guard and controlled by a three-heat switch.

The Multiversal Test Set.

A booklet recently issued by ELLIOT BROS. (London), Ltd., contains full details of their "Multiversal" test set, an instrument which recalls the many happy days we once spent in company with their "Century" standard test set. The Multiversal test set was, it will be remembered, originally designed to give the mains engineer a testing set as accurate and practical as the meter engineer or consultant found the Century set. As time has gone on, however, the scope of the original set has been enlarged and it now covers practically the whole field of direct current testing.

The test set comprises a sensitive pivoted moving coil galvanometer with specially arranged constant resistance shunts for varying the sensibility, together with a number of coils giving from 0 to 110 Ω by steps of 1 Ω (an infinity step is also provided), coupled up in conjunction with two ratio arms to form a Wheatstone Bridge. Each ratio arm consists of four coils of 1 000, 100, 10, 1 Ω, respectively, together with a special stud for use in fault localising by the Murray loop test.

A self-contained standard resistance of 100 000 Ω and a three-way switch is provided for taking the "constant" of the galvanometer and making insulation tests. By means of a constant resistance universal shunt five sensibilities can be given to the galvanometer. An enclosed key is fitted in the insulation portion of the apparatus, and a double successive key, that breaks both galvanometer and battery circuits, in the bridge part. The galvanometer is provided with external zero adjuster, and knife edge pointer and mirror scale for taking accurate readings.

An impressive series of tests can be made with the instrument, the range of voltages being from 0·75 millivolt to 1 200 V, and the current from the microampere up to any magnitude by means of external standard resistances or shunts, the instrument being direct reading in all cases. Insulation resistances and conductor resistances over wide ranges; fault localisation and capacities can also be measured.

The whole equipment is mounted on ebonite in a varnished teak case with carrying handle, and a 3-foot tripod is provided on to which the set can be screwed when in use.

COMMERCIAL INTELLIGENCE.

County Court Judgments.

[NOTE.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

ARROTA ELECTRICAL & MOTOR ACCESSORIES CO., LTD., Charles Street, Louth, electrical engineers. £20 6s. 6d. March 30.

BARTLE, Charles H., 1, Mount Parade, Harrogate, electrician. £14 6s. 6d. March 31.

BURGE, A., & CO., 300, Garratt Lane, Earlsfield, electrical engineers. £16 5s. 3d. April 6.

GAUNT & CO., Cambridge Place, Paddington, electrical engineers. £17 9s. 3d. April 11.

JEFFERYS, Arthur Neast, 8, Denman Place, Denman Street, W., electrical engineer. £48 12s. 4d. April 7.

SHEPHERD, Mr. F., 7, Hamsell Road, E.C., electrical factor. £13 6s. 5d. April 1.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

ARROTA ELECTRICAL AND MOTOR ACCESSORIES CO., LTD., Louth. Registered May 29, £15,000 debentures; charged on Great Northern Mills, Louth, also general charge. *Nil. August 23, 1921.

BRITISH DRIVER-HARRIS CO., LTD. (late DRIVER DRENNAN AND COOPER, LTD.), Manchester, cable manufacturers, &c.—Registered June 1, £14,500 mortgage. *Nil. November 8, 1921.

BUCKLEY, SAUNDERS AND CO., LTD. (late NATIONAL ELECTRIC WELDING CO., LTD.), London, S.W.—Registered May 30, £4,000 debentures, present issue £2,000; general charge. *£700. December 31, 1921.

HACKBRIDGE ELECTRIC CONSTRUCTION CO., LTD.—Registered May 31, £10,000 mortgage to A. I. Drapkin, 33, Highbury Place, N. *Nil. July 2, 1921.

MIDLAND ELECTRIC LIGHT AND POWER CO., LTD., London, E.C.—Registered June 2, £10,000 debentures, balance of £30,000; general charge. *£20,000. March 4, 1921.

SAUNDERS ELECTRICAL CO., LTD., Coventry.—Registered May 30, £1,000 debenture, to G. E. Stanley, 23A Coundon Road, Coventry, engineer and another. *£1,500. October 27, 1921.

WATFORD ELECTRIC AND MANUFACTURING CO., LTD. (late THOMAS KESNOR & CO., LTD.).—Registered May 26, conveyance supplemental to and giving further security for the moneys secured by mortgage dated November 16, 1920, and transfer of mortgage dated November 16, 1921, securing £5 000, to J. Fletcher, Carnarvon, slate manufacturer. *£5 400. August 29, 1921.

Satisfaction.

CHAGFORD AND DEVON ELECTRIC LIGHT CO., LTD.—Satisfaction registered June 7, £2,925, total amount issued of debentures registered March 1, 1911.

Private Meetings, etc.

[*Inclusion under this heading does not necessarily imply failure. Many private meetings are called merely for the purpose of the debtor consulting his creditors as to his position when he may not be insolvent.*]

PATTISON, W., asbestos-cement manufacturer, etc., Widnes. The committee of inspection which was appointed at a meeting of the principal creditors, has deferred calling the general body of creditors together to enable Mr. Pattison to come to some satisfactory terms with parties who had made tentative offers to work his processes. Mr. Pattison has reported that arrangements are now almost completed for the working of his processes which he hopes will prove satisfactory, in which event he will at once put before his creditors a scheme whereby their claims may be satisfied. The committee have no alternative scheme to recommend and suggest giving the debtor a further six months' grace, when he should call the creditors together again, whether his expectations have materialised or not, or earlier, if he has been successful, and has the details of a satisfactory scheme worked out for their discussion and acceptance.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Companies Winding-up Voluntarily.

DOYLE, Herbert, trading as ACCESSORIES SUPPLY CO., 56, Hardman Street, Deansgate, Manchester, factor in electrical accessories. Amount per £, 9s. 1d. First and final. Payable, June 21, Official Receiver's Offices, Byrom Street, Manchester.

KEYNSHAM ELECTRIC LIGHT AND POWER CO., LTD.—A. Collins, 28, Baldwin Street, Bristol, appointed liquidator.

RICKARD, WRIGHT AND DEAN, LTD.—R. S. Dawson, Tanfield Buildings, Hustlergate, Bradford, appointed liquidator. Meeting of creditors at Tanfield Buildings, Bradford, Tuesday, June 27, at 3 p.m.

Bankruptcy Information.

COATON, Thomas Green, 16, Humberstone Road, Leicester, under the style of T. G. COATON & CO., electrical engineer. First meeting, June 16, 3 p.m., 1, Berridge Street, Leicester. Public examination, July 7, 11 a.m., The Castle, Leicester.

HOGG, George James (trading as F. HOGG & CO.), 66, Waterloo Road, Smethwick, Stafford, electrical engineer. Receiving order, June 2. Debtor's petition.

Partnerships Dissolved.

BARNET, Bernard, HELLER, Myer, and LEDERMAN, Raphael, 104, Whitechapel Road, E., and 17, Maddox Street, E., under the style of THE REGENT ELECTRICAL INSTALLATION CO., by an Order of the High Court of Justice, July 29, 1921. Particulars of claims by June 15 to the Receiver, A. C. Heyward, 14-15, Coleman Street, E.C.

Bankruptcy Proceedings.

CLAYTON, Aubrey Victor, trading as CLAYTON MOTORS, Park Lane Mills, Chorley Lane, Leeds, engineer. In this matter the following are creditors:—Coquantin, M., London, £27; Electrical Apparatus, Ltd., London, £383; English, A., Leeds, £18; General Electric Co., Ltd., Leeds, £16; London Electric Wire Co. & Smiths, Ltd., London, £28; Mica & Micanite Supplies, Ltd., London, £15; Rhodes Gill & Co., Leeds, £28; Sankey, Joseph, & Sons, Ltd., Bilston, £1 493; Vono Co., Port Dudley, £470; Whitehead Bros., Farsley, £23; New Felaphone Engine Co., Ltd., Leeds, £148; Spencer, P., Bedford, £1 302; Elvey Robb & Welch, London, £275.

COATON, Thomas Green, trading as T. G. COATON AND CO., 16, Humberstone Road, Leicester, electrical engineer. The receiving order was made on May 29 on debtor's own petition. Statement of affairs shows liabilities £2 331, net assets estimated to realise £1 022, deficiency £1 309. Debtor attributes his failure to bad trade for the past two years owing to general slump, bad debts, depreciation in value of machinery and stock in trade, and ill-health of children. A private meeting of creditors was held on March 31 last, when it was decided to accept a composition of 10s. in the £ payable by instalments, satisfactorily guaranteed. For the protection of the estate, debtor executed a deed of assignment. He was unable to carry the proposed composition into effect and consequently filed his petition. Debtor states that in April, 1914, he and his brother entered into partnership and commenced business in Leicester as electrical engineers with a combined capital of £250, of which he contributed £50. In 1918 they were joined by another partner who provided £100 capital. In the same year debtor's brother retired from the business, and in August, 1919, his other partner also withdrew. The usual books of account have been kept. Debtor became aware of his position early in the present year.

KEENAN, John Norman, 63, Queen Victoria Street, E.C. The first meeting of creditors under a receiving order made against the debtor on May 24 was held last Friday. It appears that he is an electrical and rubber engineer, and has recently been trying to induce friends to form a company with the idea of manufacturing ebonite. He came to England from the U.S.A. in 1915. He has been obliged to obtain loans from moneylenders and as a result now owes £150. He says that he possesses no assets and he attributes his failure to his inability to obtain employment. The debtor consented to being adjudged a bankrupt and his affairs remained in the hands of the Official Receiver.

Arrangements for the Week.

TUESDAY, JUNE 20th.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

9.0 *a.m. to* 9.45 *a.m.* Assembly at Grand Theatre, Lichfield Street, Wolverhampton.

10 *a.m.* At the Grand Theatre, Wolverhampton. Opening of the Convention. Welcome by the Mayor; Presidential address by Mr. S. T. Allen, chief engineer and general manager of the Wolverhampton Electricity Supply Department; paper on "The Extension of the Uses of Electricity for Domestic Purposes," by Lieut.-Col. W. A. Vignoles, borough electrical engineer, Grimsby.

1 *p.m.* Luncheon at the Royal Artillery Headquarters, West Park, Newhampton Road, Wolverhampton.

2.30 *p.m.* Visit to Apley Terrace on the River Severn.

8.30 *p.m.* Reception by the Mayoress at the Art Gallery, Lichfield Street, Wolverhampton.

WEDNESDAY, JUNE 21st.

9 *a.m.* Members residing in Birmingham assemble outside the Queen's Hotel (New Street Station), where the conveyances for Stoke-on-Trent will be in readiness; members residing in Wolverhampton assemble at St. Peter's Steps.

11 *a.m.* In the Assembly Room, Town Hall, Stoke-on-Trent. Paper: "The Administration and Control of Electricity Departments," by Mr. E. Calvert, chief electrical engineer, Finchley. (A visit to Pottery Works will be arranged for any of the ladies or others who do not attend the reading of the paper. Conveyances will be in attendance at 11.15 a.m.)

1 *p.m.* Luncheon to members, delegates, and visitors, by the Stoke-on-Trent Electricity Committee, in the King's Hall, Town Hall.

2.15 *p.m.* Visit to: (1) Central Power Station; or (2) Main Electricity Sub-Stations of the Stoke-on-Trent Corporation; (3) Pottery Works*; or (4) Trentham Gardens direct.

4 *p.m.* Assemble at Trentham Gardens, where facilities for tennis and boating are available.

5.30 *p.m.* Conveyances will leave the Gardens for Wolverhampton and Birmingham.

* The following firms have arranged to conduct parties of members through their works:—Pottery Works—Cauldon Potteries, W. T. Copeland and Sons, Doulton and Co., Ltd., Mintons, Ltd., Josiah Wedgwood and Sons, Ltd.; Engineering Works—The Boving Engineering Works, Cowlishaw, Walker and Co. (1920), Ltd., Kerr Stuart and Co., The North Staffordshire Railway, The Potteries Electric Traction Co.

THURSDAY, JUNE 22nd.

9 *a.m.* Members residing in Wolverhampton should assemble at St. Peter's Steps, where the conveyances for the General Electric Company's Works, Witton, Birmingham, will be in readiness.

9.40 *a.m.* Members residing in Birmingham should assemble outside the Queen's Hotel (New Street Station).

10 *a.m.* In the Main Hall, Magnet Club, Witton. Paper: "Sub-Station Equipment, including Automatic Control," by Mr. R. A. Chattock, city electrical engineer, Birmingham.

11.30 *a.m.* Tour round the various branches of the Witton Works.

(The General Electric Co. have placed their club house, with recreation rooms and grounds, at the disposal of members. An exhibition of domestic and other electrical labour-saving appliances will also be held during the visit).

1.30 *p.m.* Luncheon at the Magnet Club.

2.30 *p.m. prompt.* Visit to Nechells Power Station of the Birmingham Corporation.

3.45 *p.m.* Conveyances will leave Nechells Power Station for the Botanical Gardens, where members will be received and entertained by the Rt. Hon. the Lord Mayor of Birmingham.

5.30 *p.m. prompt.* Leave Garden Party.

7.45 *p.m. for* 8 *p.m.* Annual dinner (evening dress), in the Royal Field Artillery Headquarters, West Park, Newhampton Road, Wolverhampton.

FRIDAY, JUNE 23rd.

9.30 *a.m.* Meeting of the Council in the Grand Theatre, Wolverhampton.

10.30 *a.m.* Annual general meeting in the Grand Theatre, Wolverhampton.

Afternoon. Visit to Wolverhampton Corporation Electricity Generating Station, Commercial Road, when the President (Mr. S. T. Allen) will personally welcome members.

WEDNESDAY, JUNE 21st.

INSTITUTION OF RAILWAY SIGNAL ENGINEERS.

3 *p.m.* At the Institution of Electrical Engineers, Victoria Embankment, London, W.C.2. Papers entitled "Light Signals," by Mr. H. E. Fawkes and Mr. W. J. Sadler.

FRIDAY, JUNE 23rd.

PHYSICAL SOCIETY OF LONDON.

5 *p.m.* At the Imperial College of Science, South Kensington, London.

1. "An Experiment on Molecular Gyrostatic Action," by Mr. J. W. Fisher, B.Sc.
2. "On the Viscous Properties and Molecular Dimensions of Silicane," by Prof. A. O. Rankine, D.Sc., and Mr. C. J. Smith, B.Sc.
3. "The Pressure-Gradient in Liquids Flowing through Cones," by Mr. W. N. Bond, M.Sc.
4. Demonstration of "A Mercury-Drop Method of Producing Visual Effects by Means of Sound," by Dr. E. E. Fournier d'Albe.

Peking Tramways.

The latest weekly bulletin to hand from the Chinese Government Bureau of Economic Information gives the following particulars of the PEKING TRAMWAYS CO. The company, it is stated, is entirely Chinese. Originally a concession was given to the Banque Industrielle de Chine, but on the representations of various public bodies, which reminded the Government that tramway undertakings are generally controlled by municipalities, the first agreement was superseded by a second, and this whittled down the concession to such an extent that the French bank was only given the privilege of appointing certain officials. The capital of the company was fixed at $4 000 000, of which $2 000 000 was to be subscribed by the Chinese public and $2 000 000 by the Government. Public subscriptions amounted to $2 000 000, so the first call was for $500 000 from the public and $500 000 fron. the Government. The arrangement between the Banque and the Government was that the latter's share of the capital should be furnished out of its credit with the Banque. However, the Banque suspended operations soon after the second agreement was signed, and left the Government to find the $500 000 unaided. There was a long delay before the money was forthcoming. Eventually the Ministry of Finance found the Government quota, and, as the necessary preliminaries had been completed, tenders were called.

There are eleven directors in the company—six elected by the Government and five by the Chinese shareholders. One of the stipulations of the agreement between the Banque and the Government was that the Peking manager of the Banque Industrielle should have a seat on the Board. That seat has been left vacant since the suspension of the Banque. The remaining ten directors—all Chinese—have met on numerous occasions, but the French bank representative has never put in an appearance, although nominally he remains a director. The company is governed according to Chinese law.

Tenders for the supply of power plant, machinery, rolling stock and accessories, have been received from the following firms: Siemens (China); Innis and Riddle; Brush Electrical Engineering Co.; Mitsui Bussan Kaisha; Arnhold Brothers; Jardine Matheson; Anglo-French (China) Corporation; Compagnia Italiana d'Estreme Oriente; Chinese Commercial Corporation; Zedelius, Westphal and Co.; Sintoon Overseas Trading Co.; Reiss and Co.; Wah-Chang Trading Co.; Liang Mao Trading Co.; Andersen, Meyer and Co. and William Forbes and Co. These tenders are being examined by a commission of experts who will make their recommendations in due course. The laying of the track is expected to be begun in the late summer.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by MESSRS. MEWBURN, ELLIS & CO., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

COMPLETE SPECIFICATIONS:

172 787 CARPENTER, R. E. H., CREED, F. G., and CREED AND CO., LTD. Electro-magnetically controlled switching-apparatus. (4/10/20.)
172 795 JOHNSON AND PHILLIPS, LTD., and WOOD, P. M. Switch-gear of the truck or similar type for electric installations. (7/10/20.)
172 805 WINTERBOTHAM, C. W. Electrically-heated sad-irons. (12/10/20.)
152 652 VOGLHUT, F. Process for the regeneration of electric incandescent lamps. (17/10/19.)
166 506 SCHAEFFER, E. Luminous electric discharge lamps. (14/7/20.) (Addition to 150 957.)
172 844 LEHMANN, G. Electric switches. (5/11/20.)
172 845 WESTERN ELECTRIC CO., LTD. (Western Electric Co., Inc.). Terminal blanks for selector switches. (5/11/20.)
172 850 CHLORIDE ELECTRICAL STORAGE CO., LTD. (Smith, E. W.). Secondary battery plates or electrodes. (12/11/20.)
172 865 RUTTER, W. V., FARRINGTON, A., and NICKLIN, G. M. Sparking-plugs for internal-combustion engines. (11/12/20.) (Addition to 136 109.)
155 264 AKT.-GES. BROWN, BOVERI, ET CIE. Apparatus for measuring the temperature of windings in electrical machines and apparatus. (12/12/19.)
172 868 BECKTON, E. Twin clip for regulating the height of electric lamps attached to flexible electric wire. (20/12/20.)
172 872 TELEGRAPHON GES. Telegraphonographs. (3/1/21.) (Additlon to 147 555.)
156 554 REINICER, GEBBERT, AND SCHALL AKT.-GES. Röntgen-ray apparatus. (23/6/15.)
156 678 REINIGER, GEBBERT, AND SCHALL AKT.-GES. Röntgen-ray apparatus. (12/1/21.) (Addition to 156 554.)
156 721 METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Electric fuses. (12/1/20.)
157 383 LEDERER, A. Electric gas-filled flow discharge lamps. (15/9/13.)
158 907 GES. FÜR DRÄHTLOSE TELEGRAPHIE. Wireless signalling in mines (9/2/20.)
172 901 COATES, W. A., DAVIES, D. R., and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Electrical switch-gear. (28/9/20.) (Divided application on 27 557/20.)
172 995 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD., BATES, P. T., MERCER, R., and GILLINGS, C. Telephone systems. (16/6/20.) (Cognate application 28 143/20.)
172 996 APOLLO PLUG MANUFACTURING CO., LTD., and BROWN, F. Electric diaphragm alarms. (24/6/20.)
172 998 CREED AND CO., LTD., and LENAGHAN, T. Electro-magnetic relays. (26/6/20.)
146 491 FOREST, L. DE. Electric signalling. (17/4/19.)
147 753 GES. FÜR DRÄHTLOSE TELEGRAPHIE. Electro-magnetic wave navigational or direction-finding systems. (23/10/18.) (Addition to 145 629.)
147 784 APPLE, V. G. Construction and operation of dynamo-electric machines. (23/4/17.)
148 445 GES. FÜR DRÄHTLOSE TELEGRAPHIE. Thermionic-tube electro-magnetic wave generating apparatus. (25/10/18.) (Addition to 148 447.)
148 447 GES. FÜR DRÄHTLOSE TELEGRAPHIE. Thermionic-tube electro-magnetic wave-generating arrangements. (9/9/18.)
148 803 HUTH GES., DR. E. F. Method of connection for producing oscillations wtih vacuum tubes. (27/9/17.)
148 995 SOC. FRANCAISE RADIO-ELECTRIQUE. Wireless telephony systems. (26/10/16.)
149 951 SIEMENS-SCHUCKERTWERKE GES. Electric are welding-apparatus. (19/8/19.)
173 009 WESTERN ELECTRIC CO., LTD. (Western Electric Co., Inc.). Telephone systems. (10/8/20.)
173 010 BYRNE, E. L. W. Submersible dynamo-electric machines. (11/2/21.) (Cognate applications, 29 380/20, 34 537/20, 4 801/21 and 10 799/21.)
173 028 BARKER, J. T., and UNITED ALKALI CO., LTD. Electrolytic cells, more especially intended for use in the production of the chlorates of the alkali metals. (10/9/20.)
173 033 SMITH, E. R. Electric calling or time-alarm devices for use in hotels and the like. (14/9/20.)
173 062 BRITISH THOMSON-HOUSTON CO., LTD., and BODDY, W. J. Oil-immersed transformers. (21/9/20.)
173 066 IMRAY, O. Y. (legal representative of Imray, O., deceased) (Bosch Akt.-Ges. R.). Electric-starting device for internal-combustion engines. (22/9/20.) (Addition to 2 815/20.)
160 746 BOUDOU, G. Electric apparatus for the permanent waving of the hair. (26/3/20.)
173 089 MARKS, E. C. R. (National Carbon Co., Inc.). Deferred-action dry battery. (5/10/20.)
173 098 GITTINS, G. E., and METROPOLITAN-VICKERS ELECTRICAL CO., LTD. Electrical oil switches. (9/10/20.)
173 125 PEARCE, H. Means for protecting alternating electric-current apparatus. (23/10/20.
173 130 ROSSI, P. Device for automatically controlling a gas or oil burner or an electrical heating element. (3/11/20.) (Cognate application, 32 307/20.)
173 134 BRITISH THOMSON-HOUSTON CO., LTD. (General Electric Co.). Systems of electric power transmission. (9/11/20.)
155 823 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD. Telephone systems. (20/12/19.)
156 494 EUSTICE, A. L. Enclosed electric fuses of the cartridge type. (22/6/14.)
161 171 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD. Automatic or semi-automatic telephone systems. (29/3/20.)

APPLICATIONS FOR PATENTS.

May 29.

15 000 A. HEWLETT. Current testing apparatus.
15 003 G. C. CLARK and W. J. H. WALTER. Removing and refitting apparatus for electric bulbs.
15 004 A. M. TAYLOR. Electric transmission systems.
15 009 E. PHILLIPSON. Electric heating apparatus.
15 019 AIR REDUCTION CO. Spark gap detector. (7/6/21 U.S.)
15 025 A. C. HESS. Electric transmission mechanism.
15 048 P. L. JENSEN and E. S. PRIDHAM. Telephone, etc., receivers.
15 049 AUTOMATIC TELEPHONE MANUFACTURING CO. Telephone systems. (6/7/21 U.S.)
15 052 F. W. UREN. Electric switchboard, etc. (29/6/21 Australia.)
15 058 V. AMBERG. Automatic telephone systems, etc.
15 087 THURINGESCHE LANDESUNWERSITÄT JENA. Dissociating oscillatory electric circuits. (27/5/21 Germany).

15 476 GENERAL ELECTRIC CO., LTD. Electric filaments. (18/6/21 Germany.)
15 481 MUIRHEAD AND CO. and E. S. HEARTLEY. Automatic telegraphy.

June 2.

15 483 BRITISH BATTERY CO. and J. W. H. REYNOLDS. Electric connections for batteries.
15 493 and 15 495 S. H. HEYWOOD AND CO. and C. L. BROWNE. Electric lifting blocks, etc.
15 494 S. H. HEYWOOD AND CO. and C. L. BROWNE. Electric controllers.
15 516 P. FREEDMAN. Electric arc devices.
15 532 E. R. MADDOX. Electrical variable condensers.
15 551 H. BOOTH. Electric heating units for irons, cookers, etc.
15 584 TELEPHONE MANUFACTURING CO. and R. L. MURRAY. Receiving apparatus for oscillating electric circuits.
15 594 A. R. MATTHEWS and R. F. TUMNER. Electrical connectors, terminals, etc.
15 596 SIEMENS and HALSKE AKT. GES. Telephone systems. (21/6/21 Germany.).

Prices of Metals, Chemicals, etc.

TUESDAY, JUNE 13.

	Price.	Inc.	Dec.
Copper—			
Best Selected .. per ton	£66 10 0	—	£1 0s. 0d.
Electro Wirebars .. ,,	£70 10 0	—	£1 0s. 0d.
H.C. Wire, basis .. per lb.	0s. 10⅜d.	—	⅛d.
Sheet .. .. ,,	0s. 10⅛d.	—	—
Phosphor Bronze Wire (Telephone)—			
Phosphor Bronze Wire, basis .. per lb.	1s. 2⅜d.	—	⅛d.
Brass 60/40—			
Rod, basis .. ,,	7d.	—	—
Sheet, basis .. ,,	9¼d.	¼d.	—
Wire, basis .. ,,	10⅛d.	⅛d.	—
Pig Iron—			
Cleveland Warrants per ton	£4 15 0	—	—
Galvanised steel wire, basis 8 S.W.G. ,,	£18 0 0	—	—
Lead Pig—			
English .. .. ,,	£26 0 0	—	—
Foreign or Colonial ,,	£24 15 0	—	2s. 6d.
Tin—			
Ingot .. .. ,,	£152 0 0	—	£2 2s. 6d.
Wire, basis .. per lb.	2s. 1d.	—	¼d.
Aluminium Ingots .. per ton	£100 0 0	—	—
Spelter .. .. .. ,,	£28 2 6	—	1s. 3d.
Mercury .. .. per bottle	£12 10 0	—	—

Sulphur (Flowers)—Ton £10 15s. *Sodium Chlorate*—Per lb. 3¼d
,, (Roll-Brimstone)—per ton £10 15s. *Sulphuric Acid* (Pyrites, 168°) per ton, £9.
Sodium Bichromate.—Per lb. 5¼d. *Copper Sulphate*.—Per ton £26 10s.
Boric Acid (Crystals). Per ton £60.
Rubber.—Para fine, 9⅜d.; plantation 1st latex, 7⅛d.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd., and the rubber prices by W. T. Henley's Telegraph Works Company.

THE ELECTRICIAN

ESTABLISHED 1861.

THE OLDEST WEEKLY ILLUSTRATED JOURNAL OF

Electrical Engineering, Industry, Science and Finance.

No. 2301. [Vol. LXXXVIII. No. 25.] FRIDAY, JUNE 23, 1922. Prepaid Subscription U.K., £1 5s. per ann.; Abroad, £1 10s. Price 6d.

CONTENTS.

Notes of the Week.

The I.M.E.A. Convention.

THE twenty-seventh annual Convention of the Incorporated Municipal Electrical Association opened at Wolverhampton on Tuesday, under the presidency of Mr. S. T. ALLEN. In accordance with our usual custom we shall defer until next week's issue a full and complete account of the proceedings, which do not conclude until Friday. We shall content ourselves here with giving some impressions gathered at an early stage in the meeting. The attendance does not seem to be so large as usual, certainly the number of ladies is less. This may be due to the strenuous times, but it is also undoubtedly partly due to the unavoidable scattering of the members over more than one town. This is both an administrative and social disadvantage, and we suggest to the Council that the time has come when precedent should be disregarded and the Convention held in some place which is either naturally or artificially designed for the accommodation of large numbers of visitors.

Wolverhampton—Past and Present.

THE Convention opened with a municipal welcome from the Mayor of Wolverhampton (COUNCILLOR JAMES THOMPSON, J.P.). Councillor THOMPSON is also chairman of the Electricity Committee. This probably saved him from declaring *ore rotundo* that electricity is still in its infancy. Instead, beginning with the Romans he connected Wolverhampton with the high lights of English history and finished by paying a tribute to the town as a health resort and to the beauty of the surrounding scenery. This caused some amusement, but everyone agreed during the afternoon that the Mayor was justified. The Black County, *in itself*, is not a thing of beauty, but it does at least heighten the contrast of mountain, woodland and river into which one drives quite suddenly when driving towards the Shropshire border.

A Brain Stimulant.

THE Presidential address was full of meat. We shall refer to it more particularly next week. Its form, as Ald. BEAUMONT suggested, is almost Baconian, and it certainly provides a cerebral stimulation whose oscillations will, we hope, effect some not too sensitive receiving apparatus. It says what everyone is thinking, which makes it seem trite. But it also indicates what everyone ought to be doing. And it is from this point of view it must be primarily regarded. It was, therefore, an excellent idea to make Colonel VIGNOLES' Paper on "The Extension of the Uses of Electricity for Domestic Purposes" a sequel to the Presidential Address. As the author pointed out, a number of domestic consumers are being supplied at a loss and the soundest, if not the obvious, method of combating this is to encourage a greater use of electricity. This is the more necessary as the domestic load is a "big thing," as large as the power load in a highly developed domestic area. To achieve a success in this direction the price must be right, there must be publicity, and the supply authority must hire and maintain. The discussion largely turned on the tariff question, and Mr. L. L. ROBINSON's remarks on this subject were particularly apposite, as were Mr. WORDINGHAM's on diversity and multiplicity of tariffs. And so to lunch and Severn scenery, and on Wednesday to Stoke-on-Trent, municipal finance, and pottery.

The Nechells Generating Station.

ON another page of this issue we give a description of the new generating station which the Birmingham Corporation have erected at Nechells. This station, which is nearing

completion, has been available for the inspection of those attending the Convention of the Incorporated Municipal Electrical Association during the present week, and the formal opening will probably take place in about a month's time. In these days of standardisation it is a little difficult to pick out from the equipment of modern generating stations anything of outstanding interest. Nechells is, however, fortunate in this respect, both from the engineering and the journalistic points of view. In the first place, orthodoxy will be shocked by the idea of using cooling towers and sewage effluent instead of the more usual river for condensing purposes. The decision required courage (perhaps the courage of despair), but experience at the Nechells temporary station shows that the practice gives rise to no difficulties and indeed forms a method of solving what, in Birmingham at least, would otherwise be a very difficult problem.

The Auxiliary Problem.

THE other main point of interest lies in the system adopted for obtaining the necessary auxiliary supply of electricity. Not only have both electric motors supplied for the main 'bus bars and steam engines been provided for this purpose, but a special auxiliary generator in addition to the exciter is carried on the main alternator shaft. Other minor points (minor because they are not quite new) are the switchgear and the building construction. The latter is mainly of concrete, and special difficulties were encountered owing to the marshy nature of the ground. The former is of the ironclad construction and combines safety with robustness in a way which, as our photographs show, is most impressive. The whole structure is an example of the best modern practice, upon the design and construction of which Mr. CHATTOCK and his assistants are to be heartily congratulated.

Coue-ism at the Post Office.

FORCE of circumstances require that POSTMASTER-GENERAL after POSTMASTER-GENERAL shall become a disciple of M. COUÉ and attempt to persuade a sceptical House of Commons, and a still more sceptical public, that the British telephone system is not only not bad, but is every day becoming better and better. Mr. KELLAWAY's task in performing variations on this theme on Friday was a good deal easier than that of some of his predecessors. It has always been the general opinion that one of the ways of improving the telephone system would be to spend more money upon it, and in announcing that a five-year programme of expansion had been prepared, involving an expenditure of some £35 700 000, he therefore carried his audience with him. This programme will be based on an estimated cumulative growth in the number of telephones of 8½ per cent., which was the actual growth in 1920-21, an estimate which is certainly on the conservative side, for if, as Mr. KELLAWAY argues, reviving trade means a greater demand for telephones, there is every reason why this figure should be exceeded, especially when the domestic demand is taken into account. But to stimulate or check that demand is largely in the Post Office's own hand.

Providing for the Future.

WE are glad to see that a large proportion of the proposed expenditure is to go in placing trunk lines underground, £504 000 being allocated for this purpose during the present year. The provision of new exchanges and the modernisation of old exchanges are other important matters which are to be taken in hand, and we hope that there will as well be plenty of provision allowed for expansion in laying subscribers' cables and junctions, so that when the demand does arise, as it assuredly will, there will be no delay in meeting it, as there has been until quite recently. How this is done in the United States was described by Mr. E. S. BYNG in the Paper he read before the Institution of Electrical Engineers some months ago, and though Sir WILLIAM NOBLE, who is an even more advanced disciple of M. COUÉ than Mr. KELLAWAY, assured the audience that everything that could possibly be done was being done over here, still there is no harm in doing just a little more. Major PURVES states that expansion is to be the first plank in his policy. We congratulate him on building on so sure a foundation, for combined with efficient working this must lead to an improved telephone system, especially if reduced charges and a more enlightened administration are the order of the day.

Wireless Legislation.

APART from the necessity for providing for the "broadcasting" craze, it is time the legislation governing the use of wireless telegraphy and telephony was put on a more satisfactory basis. The Act of 1904, which conferred certain powers of control and of issuing licences upon the POSTMASTER-GENERAL, was only meant to be a temporary measure. Actually, it expired at the end of 1906, though it has since been continued by means of the Expiring Laws Continuance Act. But Mr. KELLAWAY has now introduced a short Bill, which has already been read a second time in the House of Commons, to amend and make permanent the Act of 1904. According to the provisions of this measure wireless licences are to be subject to such terms, conditions and restrictions as the POSTMASTER-GENERAL may lay down, and penalties are provided for the contravention of the regulations or of the terms of a licence.

Three Specific Offences.

THREE specific offences are also created, viz., the sending by wireless telegraphy of a message of an offensive character, or a misleading signal as to a vessel in distress, or improperly divulging the purport of any message. For these offences a fine not exceeding £10, or imprisonment for 12 months, may be inflicted, and the penalties under the 1904 Act have also been increased. Apparently, the old distinction as to experimental licences is to disappear, and the Act is to be applied to aircraft (with the necessary modifications) and to visual or sound signalling stations for communicating with ships at sea. Provision is made for the control of wireless telegraphy, or of visual or sound signalling apparatus in cases of national emergency. The Bill seems to be devoid of definitions, and though no doubt a good deal will depend upon the Regulations, it would be well if certain technical terms were clearly and unambiguously defined. Apart from this we see little to object to in the new measure. Regulation is absolutely necessary unless we wish to get into the state of confusion and chaos which at present prevails in the United States.

The Railway Supply Inquiry.

WE had hoped that last year's exhaustive inquiry into the electricity supply problem of London and Home Counties would have been the last. But probably owing to the chaotic condition of affairs we have been compelled

to listen for the past fortnight to evidence by a succession of expert witnesses (all of whom were heard by the Electricity Commissioners at the last inquiry) on the subject of the supply for electric traction. This enquiry has been occasioned by the South Eastern and Chatham Companies being unable to obtain definite quotations for supply from the West Kent Electric Power Co. or the London Electric Supply Corporation for the electrification of their suburban lines. They therefore applied to the Commissioners for sanction to erect their own generating station at Angerstein's Wharf, Greenwich, and the enquiry into the matter occupied ten sittings.

Is a Traction Station Desirable?

In addition to the application of the railway companies, the Commissioners also investigated proposals of the West Kent Electric Power Co. for the erection of a power station at Belvedere and of the County of London Electric Supply Co. to give a supply for traction purposes from their projected station at Barking. We have given a full abstract of the evidence adduced in support of each of the three schemes and we now await the decision of the Commissioners with keen interest. The South Eastern and Chatham lines are about to be reorganised, with the London, Brighton and South Western companies, into the Southern Group of railways, and we consider it would be a misfortune if each of these three units were allowed to electrify on different systems with three separate sources of supply. The proposal to use a periodicity of 25 at Angerstein's Wharf, instead of the standard 50 periods, would also make it more difficult to introduce uniformity into a complex situation, though to adopt such a high frequency for a traction load presents many difficulties. Moreover, it is generally agreed that it would be an advantage if railway supplies were obtained from a common source as this would mean a reduction in cost. We hope, therefore, that the Commissioners will not authorise the erection of a separate traction station unless there is a manifest advantage to be gained by doing so or there is no suitable alternative source of supply which would be as cheap as that from Angerstein's Wharf.

Progressive Hackney.

Hackney Borough Council is exhibiting commendable energy and enterprise in developing its electricity undertaking. Recently it organised a successful exhibition of electric labour saving appliances for domestic purposes, and now its borough electrical engineer (Mr. L. L. Robinson) has prepared an interesting scheme for wiring the premises of the working and middle classes. Undoubtedly the chief obstacle to the more extended use of electricity in the majority of houses is the initial cost of the wiring and fittings, and the Council are now recommended to devote £5 000 out of the revenue of the undertaking in order to embark upon an experimental scheme. It is truly pointed out that the gas industry has already proved that it was essentially sound business to put in installations free, or nearly free, of initial cost to the consumer, charging a little more for gas by prepayment methods in order to avoid bad debts and to secure an adequate return both for the gas supplied and the installation. We believe Mr. Robinson is right when he says his committee should tackle the same kind of business in a similar manner.

Mr. Robinson's Scheme.

Accordingly, he recommends that consumers should be supplied, free of initial expense, with simple pendant lighting installations and cooking and heating services, but the consumer must pay outright for lamps, glassware, any special lights or certain portable articles such as immersion heaters or irons. Supply would be given through shilling-in-the-slot prepayment meters and the charge would be 2d. per unit in excess of the ordinary flat rate for lighting and ½d. in excess of the flat rate for cooking and heating, and at present this would be 8d. for lighting and 1½d. for domestic uses. A six-light installation would cost £14, and the average consumption would be 150 units a year, giving a revenue of £5 a year. Of this sum £1 5s. would be allocated for fixed charges. The cost of a complete cooking installation would be £20, and with a family of four the consumption would average 1 000 units, the revenue being £6 5s. per year, of which one-third, or £2 1s. 8d. would be taken for fixed charges. The consumer would naturally have the option of purchasing the installations at any time. We believe that the interest, sinking fund and depreciation on installations of this class should not be less than 12½ per cent., and though Mr. Robinson's estimate does not amount to this, we are inclined to agree that with the better class of consumer there would be little risk. Consequently, we hope that the Council will give the opportunity of making an experiment, which, if successful, should lead to good results for the industry as a whole.

Model Conditions of Contract.

The preparation of suitable conditions of contract is an important subject which crops up periodically at meetings of engineering and other professional associations. The ideal of a complete set of standard conditions which can be used as occasion requires will never be reached owing to the changes which are always taking place in engineering practice, necessitating constant modifications in the conditions. Nevertheless some standardisation is possible, and in the past the Institutions of Civil and Electrical Engineers, the B.E.A.M.A., the F.B.I., the I.M.E.A. and other associations have indulged in the compilation of model conditions. Recently the Association of Consulting Engineers have also exercised themselves in the preparation of a set of their own, on the ground that they found themselves unable to accept the revised set of the Institution of Electrical Engineers.

A Fundamental Weakness.

All these codes, however, have the weakness that those who prepare them have as their primary object the production of conditions which, though fair and equitable to themselves and their friends, may quite unconsciously be entirely the reverse to the other parties to the contract. For instance, the Association of Consulting Engineers, who drafted their conditions in consultation with members of the B.E.A.M.A., failed to reach agreement on two clauses relating to the limitation of the contractor's liability for negligent or improper workmanship and to the penalty for delay in completion.

Asking Too Much.

On the first point the B.E.A.M.A. desired to limit the liability for damage or loss caused by neglect or improper workmanship or design to a sum not exceeding the value of the contract. As the contractor is frequently not the maker or designer of the plant used, and as the value of the plant usually represents a substantial sum, we are disposed to think that the demand of the consulting engineers for the full

common law rights, which do not admit of any such limitation, is asking for too much. On the other hand, we think that they are right in rejecting the claim of the manufacturers to limit the penalty for delay in completion to 25 per cent. of the contract value. The usual penalty is 1 per cent. of the value of any portion of the plant for each week by which the time fixed for completion is exceeded, and thus the contractor's liability would cease at the end of 25 weeks. This is scarcely fair, as under another clause of the conditions the time is to be extended in all cases where the delay is caused by anything beyond the contractor's control.

Patent Office Report.

GOVERNMENT reports are not remarkable for their lucidity or for the ease with which information can be obtained from them, and the annual report of the COMPTROLLER-GENERAL OF PATENTS must rank as one of the worst examples. It consists of a dry record of facts, and a number of drier tables. Now a record of the trend of invention, with particulars of the subject matter of the year's patents, would make useful and interesting reading. Instead we have fourteen pages of bare summaries and arid statistics, for which the sixpence charged, represents a great deal more than the report is worth.

Past Year's Record.

WE gather that during the past year the total number of patent applications was 35 132, a decrease of 1 540 compared with 1920, and that the complete specifications filed were 19 159, or 2 637 less, mainly due to the expiry of the extensions of time granted by the Treaty of Peace with Germany and the Berne agreement of 1920. The number of new patents sealed during the year was 17 697, against 14 191. In spite of the fact that we now have women engineers, chemists and scientists, they do not appear to trouble the Patent Office examiners much, for the women inventors decreased from 311 to 297. The patents of addition also dropped from 959 to 827, but the applications by way of communication from abroad increased from 1 265 to 1 339. There were 594 requests for licences of right, and endorsements were effected in 561 cases. Only 4 of the requests were withdrawn, and 29 were still pending at the end of the year, so that the licence system seems to be pretty extensively used.

Increase of Renewal Fees.

IT is interesting to note that there was an increase in the amount of the renewal fees from £286 498 to £303 823, but less than 15 per cent. of patents survive their eleventh year, over 7 per cent. continue to the fourteenth year, and only 3·6 per cent. run the full period of 16 years. Inventors are notorious for their optimism and hopeful views, and though this high percentage of patent mortality would be enough to damp the spirits of the most ardent inventor, we do not suppose it will check the flow of invention. The inventor is the greatest public benefactor on the earth's surface, and though he seldom reaps a proper reward for his inventive skill and genius yet he has still the satisfaction of knowing that he has done something for progress and for the benefit of his fellow-man.

A Burning Question.

THE Institution of Gas Engineers has been having a joyous time at Cardiff. As members of the Institution of Electrical Engineers know, Cardiff is quite a good place to have a joyous time, but in this case its tonic qualities seem to have over-stimulated the President, Mr. JAMES ROBB, of Chepstow, to say things which he may by now regret. Mr. ROBB'S presidential address was devoted to the question, "Does the gas industry receive the recognition and respect which from its great importance is its due?" We do not propose to assist Mr. ROBB in elucidating that burning question, except to say that when it is necessary to devote more attention to pointing out what an industry has done than to what it is going to do the future of that industry is, as the Irishman said, behind it.

The Present Condition of the Gas Industry.

MR. ROBB ascribes the present condition of the gas industry (whatever that is) to Government indifference (would we had had a little of that indifference in the electrical industry), and, descending from the general to the particular, considers that the Government decided to build the Chepstow generating station solely to find employment for ex- "so-called Royal Engineers" (this is a joke, but we cannot see it) who had been trained in electricity but knew nothing about gas. But worse remains behind! When the Office of Works first investigated the relative advantages of electricity and gas for lighting the model villages at Pennsylvania and Bulwark, near Chepstow "gas came out triumphantly, which it always did when it had a fair field and no favour." Nevertheless this inept Government Department insisted on wasting public money in laying electric cables, and now the tenants of Bulwark were "clamouring for a supply of gas," which is "the finest, most diffusive, effective, healthy and cheapest artificial light for general use in existence."

A Joyous Document.

ON the other hand, electric lighting is "destructive to the eyesight, nerves and hair, and, if persisted in, would convert us into a nation of Chinese, besides exhausting our coal supplies within a very short period." The only thing that worries us about all this is, "Why Chinese?" But, more strange still, a fact of which Mr. BEAUCHAMP ought to take immediate note, "Everyone connected with electricity held a brief for it, from the top dog down to the messenger boy—including directors, shareholders and workmen's wives. Everyone of these was an active canvasser filled up to the brim with the fanciful, preposterous, unattainable virtues of electricity." Altogether a joyous document which every electrical engineer should study.

Electricity and Matter.

IN these days of labour troubles, financial stringency, and economic pressure, engineers worthy of the name will be glad to be given an opportunity of considering problems which, though of high interest, are as little affected as it is possible for problems to be by either finance or the human element. These problems include those where pure Science, with her immutable laws, is supreme. The mental tonic which such a study provides is in itself worth the labour expended, and at the same time there is the comfortable feeling that the knowledge acquired may some day be put to useful purpose in unexpected ways. An opportunity of thus widening the intellectual basis is afforded to electrical engineers in the Kelvin Lecture recently delivered by Sir ERNEST RUTHERFORD before the Institution of Electrical Engineers on "Electricity and Matter." This lecture we

have summarised on another page of this issue. Both as an historical document and from the prospect it opens of new fields of electrical development it is worth close study.

Some Necessary Expository Qualities.

Now, to make clear the hidden paths of a new and abstruse subject, such as that with which Sir ERNEST deals, certain qualities are required. Needless to say, the lecturer must know his work. He must be an enthusiast, well equipped with the talent of selection so that not only shall he avoid stressing the obvious, but that he shall give all the information that an audience not entirely composed of experts may require to assist them in understanding his arguments. All these qualities Sir ERNEST possesses. He is in the first rank of workers in the dark fields of the atomic constitution. He is an enthusiast in his work—he says so himself—and his gift of presentation has been polished by frequent delivery of lectures on the same subject.

Indeed, it would be interesting to know how many lectures on the various facets of the atomic theory Sir ERNEST has delivered during the past few months. We know of at least half a dozen ; and from the electrical engineer's point of view, and doubtless because constant practice makes perfect, the Kelvin lecture seems to have been the best of them all.

It is certainly the best for electrical engineers to study because it is a review of the great advances that have been made in recent years in our knowledge of the relations between electricity and matter, a question which is intimately bound up with the constitution of the atoms of the elements. Such a review is very useful at the present time, when some progress has been made and yet more remains to be done.

Kelvin and the Atomic Structure.

IN a Kelvin Lecture it is only fit that the subject chosen should be connected with some phase of that master's work and that his own contribution to the solution of the problem under discussion should be mentioned. This has usually been done, and Sir ERNEST did his best to follow precedent. But the task is not easy ; for though, as he pointed out, KELVIN as long ago as 1883 gave an illuminating account of the evidence that went to prove that all matter is atomic in structure, he did not accept entirely the current explanation that radio-activity is a consequence of the successive disintegrations of the atoms. To that extent, therefore, and though he devised types of atoms which under certain disturbances broke up with explosive violence simulating in behaviour the atoms of radium, the trend of modern thought and work has rather been away from than in continuance of his ideas.

The Modern Line of Thought.

WHAT that modern line of thought is was clearly laid down by the lecturer. FARADAY'S laws of electrolysis form a remote beginning, followed, after a long interval, by JOHNSTONE STONEY, TOWNSEND, and MILLIKAN showing conclusively that the charge carried by the electron is numerically equal to that carried by the hydrogen ion in the electrolysis of water, and thus allowing the mass of the atom of all the elements to be deduced. Moreover, CROOKES' assumption that the different properties of the elements were not due to the existence of different kinds of matter, but to different quantities and arrangements of a single fundamental " substance," was an advance of importance.

The Constitution of the Atom.

THE next stage was the conception that the atoms of the different elements, so far from being indivisible, have a common complex structure made up of protons (or units of positive electricity) and electrons. Progress during the past twenty years has mainly depended on a clearer understanding of the relative part played by positive and negative electricity in the atomic structure, and it is now generally accepted that the atom is an electrical system. Further, the nuclear charge of any element is identical with the number of the places into which that element falls in the series originally discovered by MENDELEEFF from other considerations.

Transmutation of the Elements.

IF we accept these theories, it is but a step to the idea that one element can be changed into another, so that a very old dream for which many worked and suffered has at last been realised. Sir ERNEST himself has bombarded a number of the lighter elements with α particles, and has thereby succeeded in breaking up nitrogen into hydrogen and helium. We hasten to add for the benefit of those who would otherwise entertain ideas of alchemical wealth that this disintegration has only been effected on a very small scale, and that most of the atoms are stable bodies held together by enormously great forces.

The Engineer and Atomic Disintegration.

BUT nevertheless it is upon the part of Sir ERNEST'S lecture which deals with this subject of disintegration that the imagination of the engineer may well fix. For it is conceivable that in the energy changes which take place as a part of these phenomena is to be found the solution of some of our present difficulties in power generation. Great as are the advances in the economic utilisation of fuel that have been made during the past few years, the total efficiency of the process is still low, and this means, among other things, that we are expending our resources without adequate return. We do not mean to suggest that within the next few years our generating stations will be equipped with plant for transforming nitrogen into hydrogen and helium ; or that the place of the present boiler house staff will be taken by bespectacled workers from the Cavendish laboratory engaged in these pursuits. But the possibility of utilising the energy set free by the disintegration of the complex atom into something simpler does suggest methods which must for every reason receive the fullest investigation.

Atomic Structure and the Strength of Materials.

THE problem has another aspect which should be of more immediate importance to the engineer. For the greater our knowledge of the atomic structure the greater will be the information we shall be able to obtain of the capabilities of the materials that are being employed in engineering, until the point is reached when methods of trial-and-error can be replaced by definite knowledge, a state which will not only be of theoretical but of practical engineering advantage. As it is, X-ray analysis is being used to obtain fresh information on the internal structure of metals and their behaviour under heat and stress. More might well be done on these lines, for, after all, that is only a first step towards linking up more closely the work of the theoretical physicist with the solution of problems of a most practical nature. In this linking up lies one of the brightest chances of future progress in many fields.

C

Electricity and Matter.*

By SIR ERNEST RUTHERFORD, F.R.S.

In the Kelvin lecture Sir Ernest Rutherford gives a review of the great advances made in recent years in our knowledge of the relations between electricity and matter. This leads to a consideration of the fundamental problem of physics—the constitution of the atoms of the elements.

In the earlier Kelvin lectures it has been customary to give an account of some phase of Kelvin's work. This could easily be done this evening by concentrating on the publications of Kelvin that deal with the proof of the atomic nature of matter, the dimensions of atoms and molecules, including the first suggestions of the mechanism of atomic constitution. This was a subject in which Kelvin was permanently interested. In his Royal Institution lecture of 1883, reprinted in "Popular Lectures and Addresses," vol.i, he gives an illuminating account of the different lines of evidence that all converge to a cumulative proof that matter is coarse-grained or atomic in structure and set a definite minimum limit to the dimensions of the atom. His deduction of the diameter of the water molecule from the cooling effect observed when a water film is stretched, is one of the most notable of his examples. In his later papers, he accepts Stoney's arguments in support of the atomic nature of electricity and in a paper of curious title "Æpinus Atomized,"† he restates the old theory of Æpinus of the nature and relation of positive and negative electricity in a more modern form by assuming that the negative electricity in an atom is distributed in the form of definite units called "electrions" held in equilibrium embedded in a sphere of uniform positive electrification. In some of his later papers Kelvin devised types of atoms which, under certain disturbances, broke up with explosive violence, simulating in behaviour the atoms of radium. While keenly interested in such speculations, there remained the curious anomaly that he did not entirely accept the current explanation that radio-activity was a consequence of the successive disintegrations of atoms.

An Event of Extraordinary Significance.

The discovery in 1897 of the individual existence of the negative electron of small mass, and the proof that it was a component of all the atoms of matter, was an event of extraordinary significance to science, not only for the light which it threw on the nature of electricity but also for the promise it gave of methods of direct attack on the problem of the structure of the atom.

The Relationship between Electricity and Matter.

The first definite proof of the close relations that exist between electricity and matter we owe to the famous experiments of Faraday on the passage of electricity through electrolytes. After a long interval the suggestion of the atomic nature of electricity was mentioned by Maxwell and Helmholtz, although with reservation, but was revived with conviction by Johnstone Stoney, who suggested that the name "electron" should be applied to the fundamental unit of electricity and made a rough estimate of its magnitude. Following the discovery of the independent existence of the electron and the proof of the production of charged ions in gases by X-rays and other radiations, it was implicitly assumed by scientific men that electricity must be atomic in nature, and all the experimental data were interpreted on this view.

Nature of the Negative Electron.

It was soon recognised that the negative electron of small mass was an actual disembodied atom of electricity and that its apparent mass was electrical in origin. J. J. Thomson had early shown (1881) that a charged body in motion behaved as if it had an additional electric mass due to its motion. The experiments of Kaufmann and others on the swift electrons ejected from radium showed that the mass of the electron, while sensibly constant for slow fields, increased rapidly as the velocity of the electron approached that of light. Later, Einstein from considerations of relativity showed that for any material particle, whether charged or not, the mass m must vary with speed according to the relation $m/m_0=(1-\beta^2)^{-\frac{1}{2}}$, where m_0 is the mass for low speeds, and β is the ratio of the velocity of the particle to the velocity of light. Experiment has been shown to agree closely with this calculation.

The Positive Electron.

One of the main difficulties in the attack on the question of atomic constitution has lain in the uncertainty of the nature of positive electricity. The evidence as a whole supports the idea that the nucleus of the hydrogen atom is the positive electron. It might *a priori* have been anticipated that the positive electron would be the counterpart of the negative electron and have the same small mass. There is, however, not the slightest evidence of its existence. The unsymmetrical distribution of positive and negative electricity that is characteristic for all atoms is a consequence of the wide difference in the mass of the ultimate electrons which compose their structure. No explanation can be offered at the moment why such a difference should exist between positive and negative electricity.

Estimates of Electron Mass.

On the classical electrical theory the mass of the electron can be accounted for by supposing that negative electricity is distributed on a spherical surface of radius about 1×10^{-13} cm. In some recent theories of Compton and others it has been supposed that the electron behaves like a flexible ring whose dimensions are about 10^{-11} cm, or about 100 times the original estimate. Without going into these difficult questions, what little experimental evidence there is seems to support the older estimate of size. Taking this view the greater mass of the proton or unit of positive electricity is to be explained by supposing that the distribution of electricity is much more concentrated for the proton than for the electron. Supposing the shape spherical, the radius of the proton should be only 1/1800 of that of the electron.

The Nuclear Theory of the Atom.

Progress in our knowledge of atomic constitution during the last twenty years has depended mainly on a clearer understanding of the relative part played by positive and negative electricity. It is now generally accepted that the atom is an electrical system, and that the atoms of all the elements have a similar type of structure.

The nuclear theory of atomic constitution has been found to be of extraordinary value in offering an explanation of the fundamental facts that have come to light, and is now generally employed in all detailed theories of atomic constitution. On this view of the atom the problem of its constitution naturally falls into two parts, one the distribution and mode of motion of the outer electrons and the other the structure of the nucleus and the magnitude of the resultant positive charge carried by it. In a neutral atom the number of external electrons is obviously equal to the number of units of positive (resultant) charge on the nucleus.

The general conception of the nuclear atom arose from the need of explanation of the very large deflections experienced by swift α and β particles in passing through the atoms of matter. The next great advance we owe to the experiments of Moseley on the X-ray spectra of the elements. He showed that his experiments received a simple explanation if the nuclear charge varied by one unit in passing from one atom to the next. In addition, it was deduced that the actual magnitude of the nuclear charge of an atom in fundamental units was equal to the atomic or ordinal number when the elements were arranged in order of increasing atomic weight. On this view, the nuclear charge of hydrogen is 1, of helium 2, lithium 3, and so on up to the heaviest element, uranium of charge 92.

Bohr's Distribution Theory.

It is now generally supposed that the electrons are arranged in groups or shells round the nucleus. The theory of Bohr offers a general explanation of the periodic variation in the properties of the elements and even accounts for the presence of the group of rare earths where the chemical properties of successive elements closely resemble one another. It endeavours to account not only for the light spectra but also for the X-ray spectra of all the elements. While it is too soon to express a definite opinion of how far it is capable of explaining the great multitude of facts known about the elements, there can be no doubt that a substantial advance

* Abstract of the Thirteenth Kelvin Lecture delivered before the Institution of Electrical Engineers.

† "Philosophical Magazine," March, 1902.

has been made in the attack of this most fundamental of problems which lies at the basis of physics and chemistry.

The Structure of the Nucleus.

The most definite information on the structure of the nucleus has been obtained from a study of the modes of disintegration of the radio-active atoms. In the great majority of cases the atoms break up with the expulsion of a single α particle which represents the doubly charged nucleus of the helium atom; in other cases a swift β ray or electron is liberated. The expulsion of an α particle lowers the nuclear charge of the atom by two units and its mass by four, while the expulsion of an electron raises it by one. On this simple basis we can deduce the atomic number and the general chemical properties of the long series of radio-active elements and understand the appearance in the radio-active series of isotopes.

Elements Without Isotopes.

Some very definite and important information on the structure of nuclei has been obtained by Aston in his experiments to show the existence of isotopes in the ordinary stable elements by the well-known positive-ray method. He found that a number of the elements were simple and contained no isotopes. Examples of such "pure" elements are carbon, nitrogen, oxygen and fluorine. It is significant that the atomic weights of these elements are nearly whole numbers in terms of O=16; on the other hand, elements such as neon, chlorine, krypton, and many others consist of a mixture of two or more isotopes of different atomic masses. Aston found that within the limit of error the atomic weights of these isotopes were whole numbers on the oxygen scale. This is a very important result, and suggests that the nuclei of elements are built up by the addition of protons of mass nearly one in the nuclear combination.

Disintegration of the Elements.

To obtain evidence to prove that the proton exists as a unit of the structure of the nucleus the obvious method is to effect the disintegration of some of the ordinary elements and to examine the masses and charges of the ejected fragments. In order to test whether the atoms can be artificially disrupted, a stream of α particles have been employed to bombard the atoms of the material under examination. When a stream of α particles is passed through oxygen or carbon dioxide, a few long-range particles are observed which appear to be H nuclei liberated from hydrogen present in the radio-active source. When dry air or pure nitrogen is used, the number of particles is three or four times as numerous and of greater average range. These swift particles are bent in a magnetic field as if they were hydrogen nuclei, and it was thus concluded that they arose from the disruption of the nitrogen nuclei due to close collisions with α particles.

Examination of the Lighter Elements.

Further progress has depended mainly on improving the methods of counting the weak scintillations produced by these particles. Dr. Chadwick and the author have made a systematic examination of a number of the lighter elements and have found that similar long-range particles are liberated from boron, fluorine, sodium, aluminium and phosphorus, as well as from nitrogen. The range of the particles in all cases is greater than that of the H particles liberated from free H atoms under similar conditions. In some recent experiments it has been found that these long-range particles are bent in a magnetic field as if they were hydrogen nuclei. While it is very difficult to measure the mass of these flying particles with accuracy, there can be little doubt that the long-range particles from these elements consist of hydrogen nuclei in all cases. The maximum speed of emission of these nuclei depends on the speed of the bombarding α particle and varies from element to element.

These results suggest that the elements are in the main built up of helium nuclei, mass 4, and protons. The α particle is unable to liberate a proton from elements like carbon or oxygen which are built up entirely of helium nuclei as secondary units, but can do so from an element like fluorine which presumably is built up of 4 helium nuclei and 3 protons.

Disintegration by α Particles Small.

It should be borne in mind that the disintegration effected by α particles is on a very minute scale. Only two protons are liberated from aluminium for a million α particles traversing it. This disintegration has been observed only by the utilization of such a sensitive method that the individual proton can be counted. In some cases the energy of the expelled proton is greater than that of the α particle which liberates it. For aluminium, the proton has a maximum energy about 40 per cent. greater than that of the α particle. There thus appears to be a gain of energy in some cases, and this excess energy is presumably derived from the nucleus.

Radio-Active Evidence.

From the radio-active evidence, we know that the nuclei of heavy atoms are built up, in part at least, of helium nuclei and electrons, while from the experiment outlined above it seems clear that the proton can be released from the nuclei of certain light atoms. It is, however, very natural to suppose that the helium nucleus which carries two positive charges in a secondary building unit composed itself of a close combination of protons and electrons—viz., 4 protons and 2 electrons.

From the point of view of simplicity, such a conception has much in its favour, although it should be mentioned that it seems at the moment impossible to prove its correctness. If, however, we take this structure of the helium nucleus as a working hypothesis, certain very important consequences follow. On the oxygen scale, the helium atom has a mass very nearly 4·000, while the hydrogen atom has a mass 1·0077. The mass of the helium atom is thus considerably less than that of four free H nuclei. Disregarding the small mass of the electrons, in the formation of 1 gm. of helium from hydrogen there would be a loss of mass of 7·7 milligrams.

The First Fruits of the Investigation.

It has been pointed out by Perrin and Eddington that in all probability the energy of radiation from our sun and the stars is mainly derived from the enormous emission of energy accompanying the formation of helium from hydrogen. If this be the case, it is easy to show that sufficient energy can be derived from this source for our sun to radiate at its present rate for several thousand million years. This interesting suggestion of the probable origin of the greater part of the enormous energy radiated by the sun and stars is one of the first-fruits of the investigations on the structure of atoms. It is believed that the formation of helium from hydrogen occurs under certain conditions in the great central furnace of the sun and stars. There is no evidence so far that this combination can be produced under laboratory conditions. It may be that it can be effected only under conditions of very high temperature and enormous intensity of radiation such as occur in the interior of a sun. Even then the process of formation may go on at a very slow rate and for periods measured by millions of years.

Atoms Purely Electrical Structures.

It is hoped that it has been made clear that most workers on the problem of atomic constitution take as a working hypothesis that the atoms of matter are purely electrical structures and that ultimately it is hoped to explain all the properties of atoms as a result of certain combinations of the two fundamental units of positive and negative electricity—viz., the proton and electron. During recent years, unexpectedly rapid advances have been made in our knowledge of this subject, but we have only made a beginning in the attack on a very great and intricate problem.

Future Work.

Great difficulties arise the moment we consider why the nucleus of an atom holds together, and progress seems likely to be slow because it seems clear that the ordinary laws of force between electrified particles break down at such minute distances. There are, however, a number of obvious lines of attack that may yield us very valuable information. In particular, a closer study of the modes of transformation of radio-active bodies may be expected to give us much more important data. During recent years the study of the γ or very penetrating X-rays from radio-active bodies has progressed very rapidly. The general evidence indicates that the γ rays like the α and β particle have their origin in the nucleus. The study of the γ rays thus gives us information of the frequency of vibration of the electrons which form part of the nuclear structure. In addition, Ellis has shown that it appears probable that the laws of quantum dynamics which govern the motions and vibrations of the outer electrons apply also to the nuclear electrons. If this conclusion can be verified, it offers the hope that we may later be able to form some idea of the detailed structure of nuclei. Harkins has pointed out some very interesting relations that appear to exist between the relative abundance of elements in the earth and their atomic number, while the close study of stellar evolution should ultimately throw much light on the general problem.

Electricity Supply in Birmingham.

Details of the New Nechells Generating Station.

At the time when the Annual Convention of the Incorporated Municipal Electrical Association was held in Birmingham eight years ago, it was common though unofficial knowledge that the demands of the consumers of the electricity department had caused the Electricity Committee, on the advice of Mr. R. A. Chattock, to purchase a site at Nechells, on the outskirts of the city, and that preliminary work had been started there for the erection of a generating station. But Birmingham, fortunate enough in some ways, is not well favoured with places where power stations, which conform to modern ideas of design, can easily be erected. Coal supply is abundant, but water supply, owing to the absence of rivers, is more than usually limited. At Summer Lane, which was the principal generating station in 1914, a combination of canal water and cooling towers are used, but for this reason and owing to more physical difficulties connected with the site the ultimate capacity of 36 500 kW has been reached. Hence the original reason for building afresh at Nechells.

The Effect of the War.

So far the history of electricity supply development in Birmingham does not differ very greatly from that in many other towns. Nechells opens a new phase In the first place, it was decided to use the sewage effluent from the neighbouring sewage farm for cooling purposes, thus overcoming in an ingenious and successful way a problem which must always arise in towns situated as Birmingham ; and secondly, the outbreak of the war first caused the work to be discontinued ; then when an urgent demand for power and yet more power was made a temporary station had to be built ; and lastly, in 1919, work was resumed on the permanent station, work which is just now nearing completion.

A "Permanent-Temporary" Station.

It may be pointed out, however, that in spite of alternate booms and slumps demand has more than kept pace with supply. As a result the "temporary" station is in a fair way to become permanent and will at least be retained in use until some coalition between its plant and that in the "permanent" station can be made. For the time being the two stations feed into the network and are interconnected through special cables. The Nechells permanent station has a present capacity of 30 000 kW and an ultimate capacity of 105 000 kW.

A detailed description of the Nechells temporary station will be found in THE ELECTRICIAN, Vol. lxxv., p. 388, June 18, 1915. Its genesis was due to the reason mentioned above and to the fact that no other site could be found for the erection of the generating plant that was so urgently needed. Fortunately a site adjacent to the permanent station at Nechells was available, and here a station of 10 000 kW capacity was erected and got to work in the short space of eight months. This was partly achieved by making the buildings of a steel framework, covered with asbestos composition corrugated sheeting, an arrangement which, incidentally, saved a great deal of money. This station was subsequently increased to 22 000 kW capacity.

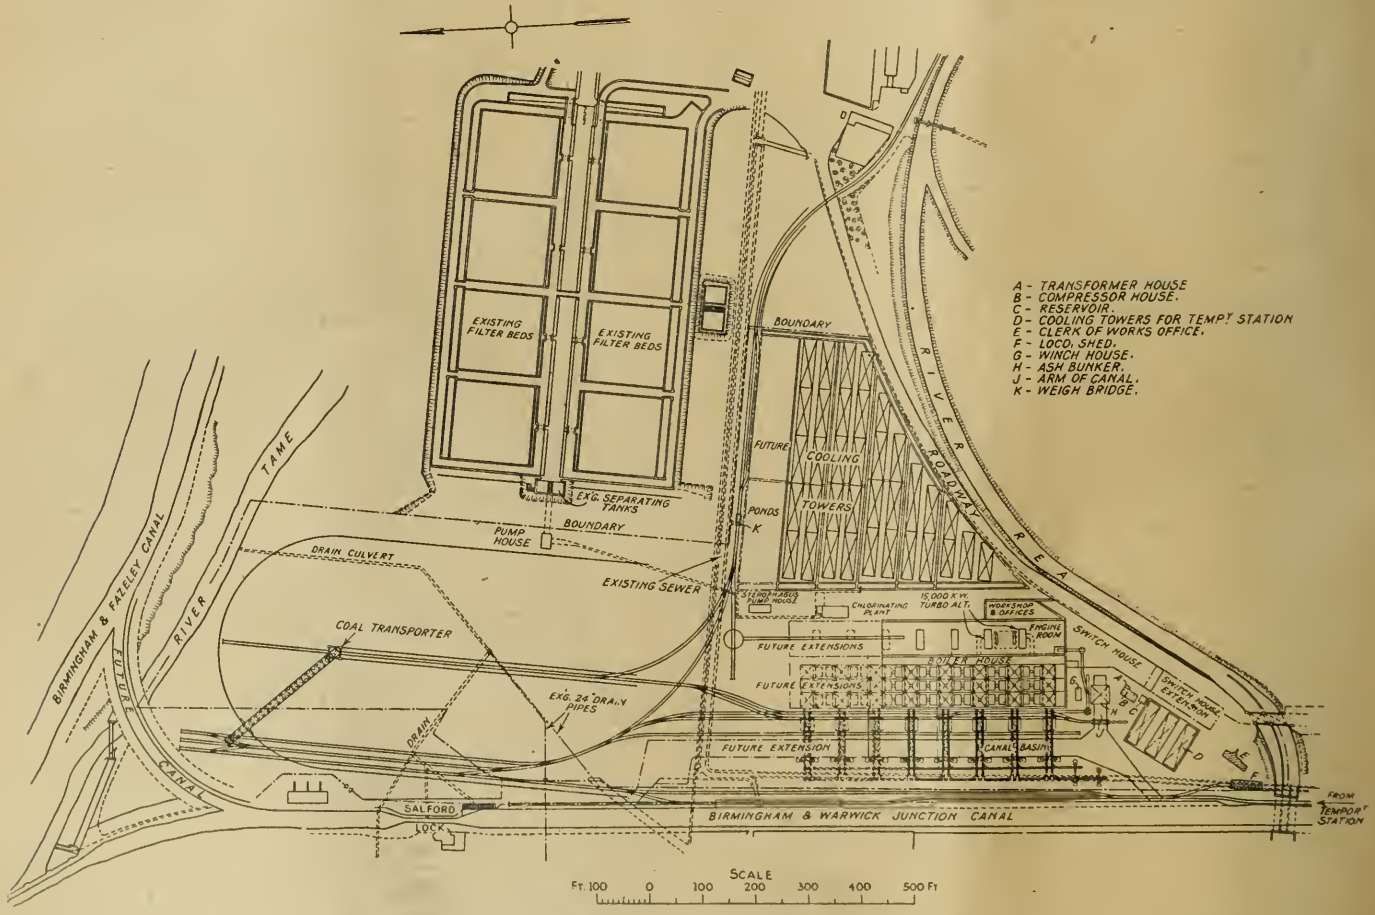

FIG. 1. SITE PLAN OF THE NECHELLS STATION.

Site of Permanent Station.

Turning now to the permanent station, the site utilised has an area of about 21 acres and is situated close to an industrial area where large power loads will be available. The surroundings are very open, and the site is bounded on one side by the Birmingham and Warwick Junction Canal. Railway connections can be made both to the Midland Railway main line to Derby and to the London and North Western Railway branch line from Stechford via Aston to the Black Country and Cannock Chase coalfields. Fig. 1 shows the boundaries and surroundings of the station.

As mentioned above, the site is close to a large block of filter beds belonging to the Tame and Rea District Drainage Board, from which approximately 3 000 000 gallons per day of filtered sewage effluent can be obtained for make-up for the towers used for cooling the condensing water.

Station Details.

The generating station, which is designed for an ultimate capacity of 105 000 kW, consists of an engine house, boiler

house, switch-gear house, workshop and offices, with cooling water reservoirs and towers, telpher system for coal and ashes, private canal basin having access to the Birmingham and Warwick Junction Canal (which is to be widened), railway sidings connected to the Midland Railway, and large coal storage accommodation. Fig. 1 shows the general lay-out, the portion shown in full lines being that already equipped, while the dotted lines indicate space available for future extensions.

Buildings.

It was determined after careful examination and consideration that, as the soil was composed largely of sewage sludge, and was soft, spongy and waterlogged in wet weather (being on the site of an old sewage farm), it would be necessary to support the whole of the buildings on ferro-concrete piles of a sufficient length to reach down to the bed of sandstone which runs pretty uniformly over the whole area, 17 ft. below surface.

The general plan of foundations was carried out on the Mouchel-Hennibique system of ferro-concrete construction. The total load on each cluster of piles in the boiler house is 276 tons, along the line supporting the wall separating the engine and boiler houses. The foundation raft constituting the basement floor of the boiler house consists of a slab of ferro-concrete 4 in. thick, divided by main secondary concrete beams into panels 13 ft. long by 5 ft. 3 in. wide.

The beds for the turbine foundations in the engine house consist of ferro-concrete slabs 15 in. thick, supported on 14 in. square piles, the total load on each bed being 1 180 tons. On the top of these come the massed concrete turbo-alternator foundations, bringing the level up from the basement to that of the operating floor.

The building work was carried out under the supervision of Messrs. A. Jackaman and Son, Ltd., of Slough. The architectural work was entrusted to Messrs. Ewen Harper, Bro., and Co., and the design of the ferro-concrete work to Messrs. L. G. Mouchel and Partners, Ltd.

Cooling Tower Foundations.

The foundations for the cooling ponds and cooling towers involved some very heavy ferro-concrete beam work and containing walls. The cooling ponds carry 10 ft. 6 in. depth of water, and are entirely above ground level. The whole system of beams is connected by a continuous slab of concrete 5 in. thick, forming the bottom of the ponds. An idea of the extent of the cooling tower system may be gained when it is remembered that there are at present 17 towers installed, and that there will ultimately be no less than 41 towers.

Owing to the shortage of bricks and of labour in the building trade, the architects desired to reduce to a minimum the employment of such trades as would be drawn upon largely in the erection of domestic houses, and decided to carry the whole weight of the structure and equipment upon steel stanchions and girders. The brickwork shell could then be considered as a covering only, with the result that the walls above ground-level in no case exceed 14 in. thick.

General Arrangements.

The engine house, see Figs. 2 to 5, at present measures 218 ft. 9 in. in length by 66 ft. 3 in. in width by 72 ft. high (to the underside of the roof); but an extension of 65 ft. 9 in. for the third turbo is now being commenced, and for future requirements there is a further extension available of 240 ft. 9 in., making an ultimate length of 525 ft. 3 in.

The boiler house at present measures 218 ft. 9 in. in length by 98 ft. wide by 54 ft. high; but an extension of 306 ft. 6 in. is available for future extensions, making an ultimate length of 525 ft. 3 in. The feed tank floor is at a height of 36 ft. above firing floor, and the pump room floor at 18 ft. above firing floor. The steel chimneys (104 ft. high) are carried upon a platform at a height of 32 ft. above firing floor.

The workshop and office block adjoins the engine house, and consists of stores, messrooms, workshop, battery room and offices.

The switch house block (see Fig. 1) adjoins the end of office block and of engine house, and consists of a covered yard (in which is situated a turn-table), control room, switch room, galleries, etc., a section of the building being in three storeys and the rest in two storeys; a granolithic staircase giving access to all floors. The transformer cubicles, for the 30 000 V transformers, are built into the west side of the switch-house block, at yard level.

The Control Room.

The control room occupies one end of the floor over the cartway, and covers an area of 5 400 super. ft., and is 20 ft. high. It has access to the engine room by the main staircase and is provided with large windows on both outer walls and towards engine room.

The switch room adjoins the control room, and has a height of 32 ft. a width of 44 ft. and a length of 79 ft. 2 in. On the floor of this room are situated the heaviest (or "M") oil switches. The general arrangements of the station are given in Figs. 2 and 4.

Coal-Handling Plant.

The contract for the coal and ash-handling plant was let to the Mitchell Conveyer and Transporter Co. The coal-handling plant was required to deal, on a large scale: (1) With coal arriving by railway truck, or (2) by barge. In the first case plant had to be provided for tippling the trucks bodily over the grabbing pit, then for removing the coal at the rate of 40 tons per hour per boiler house bay; lifting it through a height of 50 ft., traversing it from 200 to 300 ft., and dropping it into the coal bunkers situated over the various boiler-house sections at the top-floor level of boiler-house.

In the second case, the plant had to be suitable for lifting the coal by means of grabs out of the barges in the canal, or the canal siding, at the rate of 30 tons per hour per boiler-house bay, traversing some 200 to 300 ft. (ultimately some 500 ft.), lifting it some 50 ft. and dumping into the hoppers in the various boiler-house bays, at the top-floor level.

The wagon tipplers for discharging the railway trucks on to the coal dumps are entirely automatic, and are the latest form of labour-saving device. They can deal with 120 tons of coal per hour. Special advantages are claimed for this form of tippler, in the matter of distribution of the coal, quick handling later by the grabs, and avoidance of damage to railway trucks.

Ash-Handling Plant.

The ash-handling plant is required to collect the ashes and riddlings from the hoppers under the boilers (of which there will ultimately be 42), carry them to a convenient storage centre, and feed them from thence either into railway wagons or into barges. For the first three boiler sections equipped the capacity of the plant is sufficient to deal with 30 tons of ashes, clinker and riddlings per hour.

There are two trucks and an electric locomotive for dealing with the ashes and clinker, and one truck for dealing with the riddlings. A complete system of 30 in. tracks is laid under the boilers in the basement. These lead to the foot of the two ash hoists.

The capacity of the ash bunker, which is of ferro-concrete construction, is 300 tons.

Cooling Towers and Circulating Water System.

The sewage effluent used for cooling is first passed into a chlorinating house, where it is sterilised by chlorine treatment. Thence it passes through a suction culvert to the condensers, and from the condensers it is forced through discharge piping to the tops of the sprayers in the cooling towers and thence falls into the cooling ponds.

The contract for this work was divided up as follows: Cooling tower foundations, including cooling ponds and suction culvert and chlorinating house, A. Jackaman and Son, Ltd.; cooling towers, The Davenport Engineering Co.; heavy suction and discharge pipework and valves connecting cooling towers with condensers, E. E. Jeavons and Co.

The cooling towers are of the natural draught chimney type, capable of dealing with a total capacity on normal full load of 2 877 500 gals. of water per hour, reducing the temperature from 92° F. to 75° F., with atmosphere at 55° F. and 80 per cent. humidity.

There is a "main" trough, two "intermediate" troughs, and a large number of "distributing" troughs in connection with each tower. An excellent view of these cooling towers is given in Fig. 3.

Boilers and Steam Piping.

The boilers and steam and feed piping were supplied by Babcock and Wilcox, and the chimneys and Prat induced draft arrangements by Utting and Co. The first section of plant consists of twelve land type marine water tube boilers, each complete with an integral superheater, superposed steel tube economiser, and chain grate stokers.

Each boiler has a heating surface of 5 348 sq. ft.; the superposed steel tube economiser having a further heating surface of 3 393 sq. ft., making a total effective heating surface of boiler and economiser of 8 741 sq. ft. The boilers are constructed for a working pressure of 320 lbs. per sq. in., while

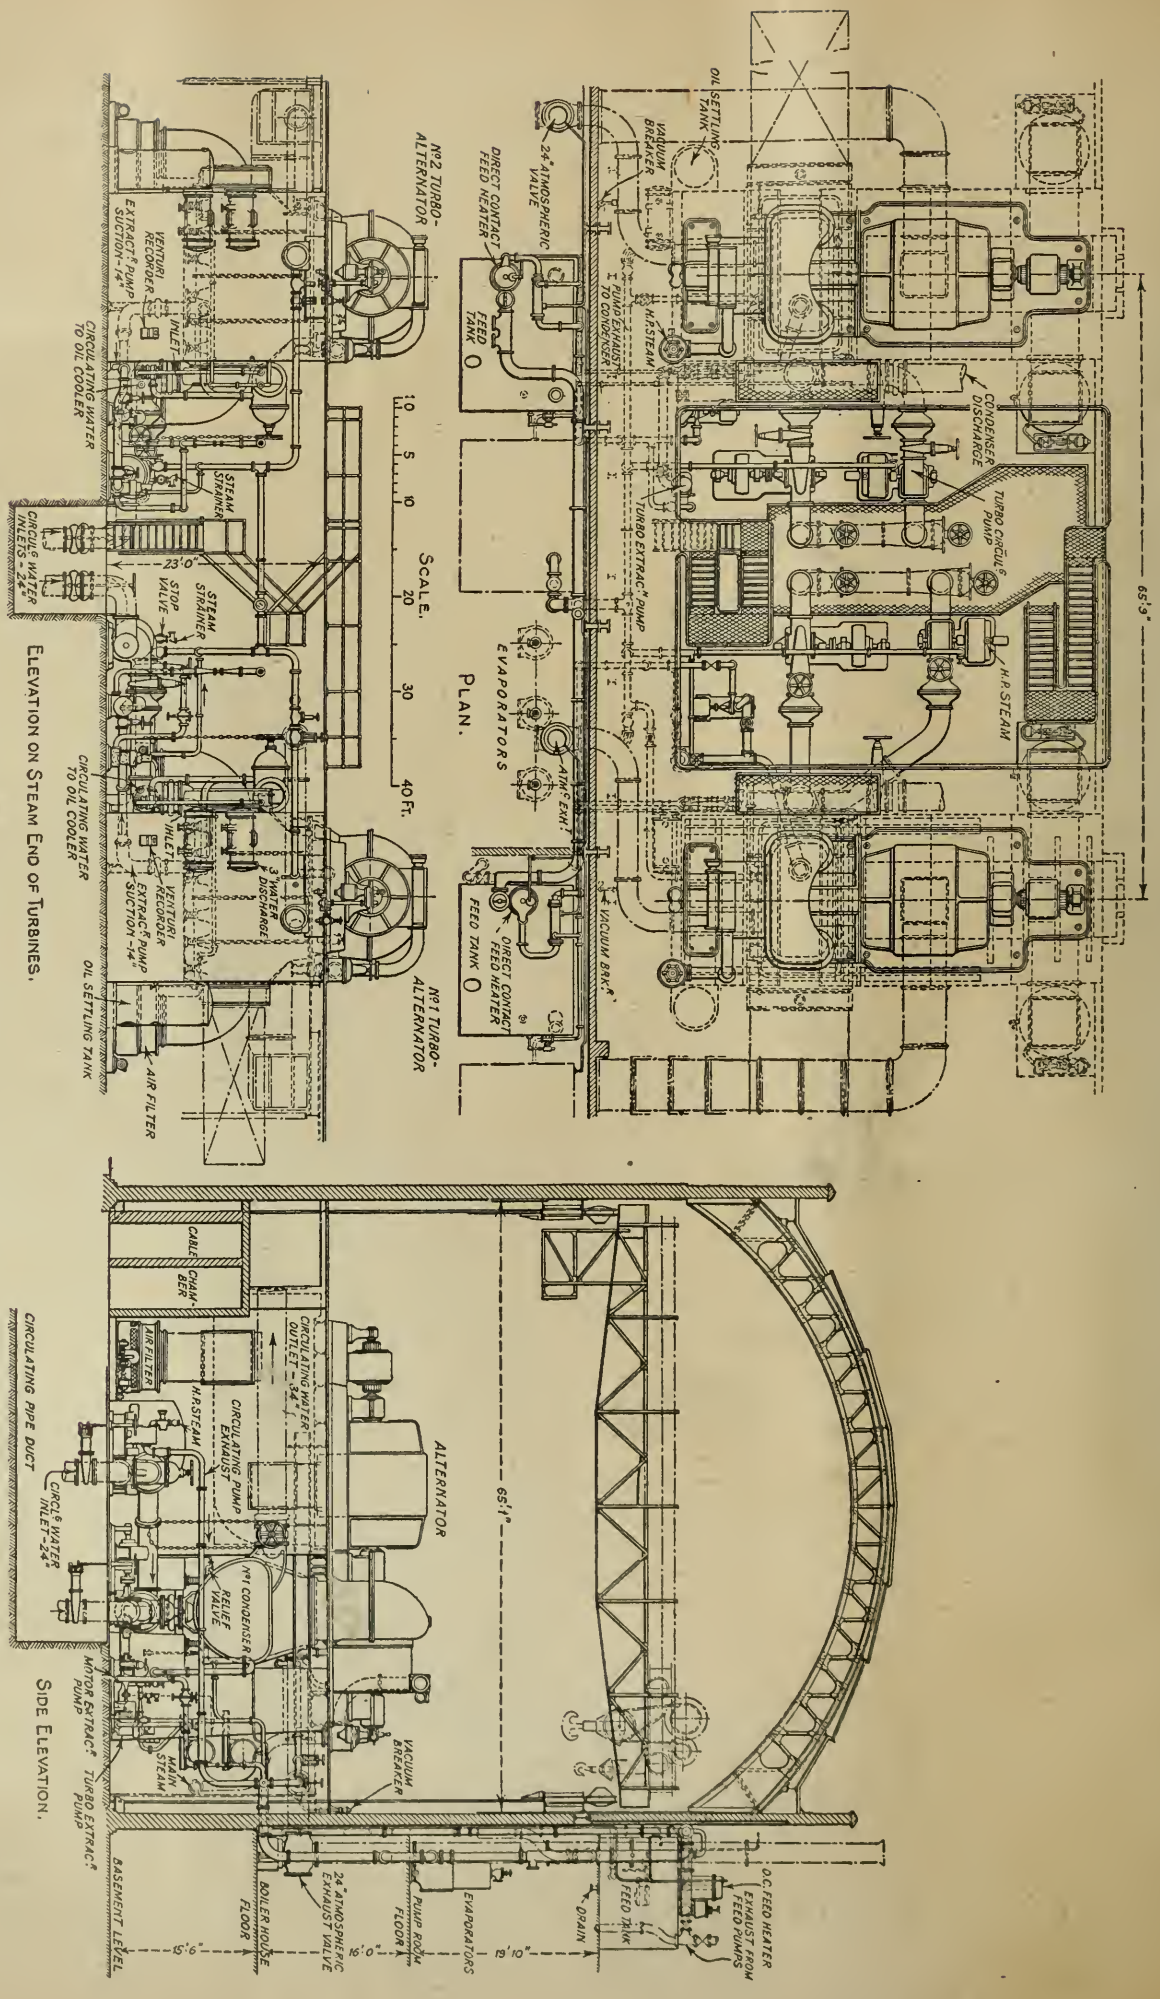

Fig. 2.—Plan and Elevations showing general arrangement of Turbo-alternators, Condensing Plant, Pumps, etc., at Nechells.

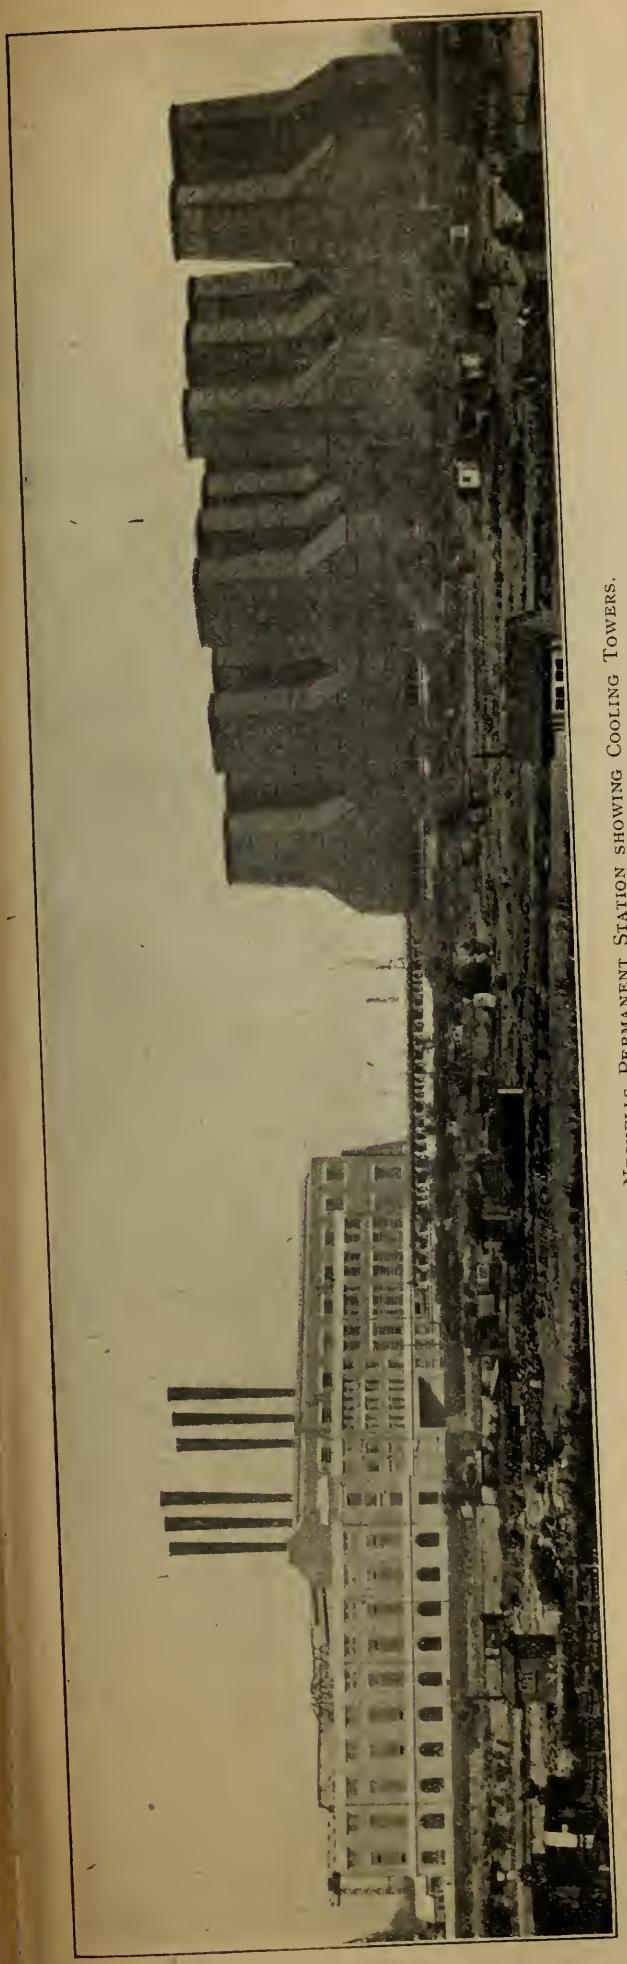

Fig. 3. View of Nechells Permanent Station showing Cooling Towers.

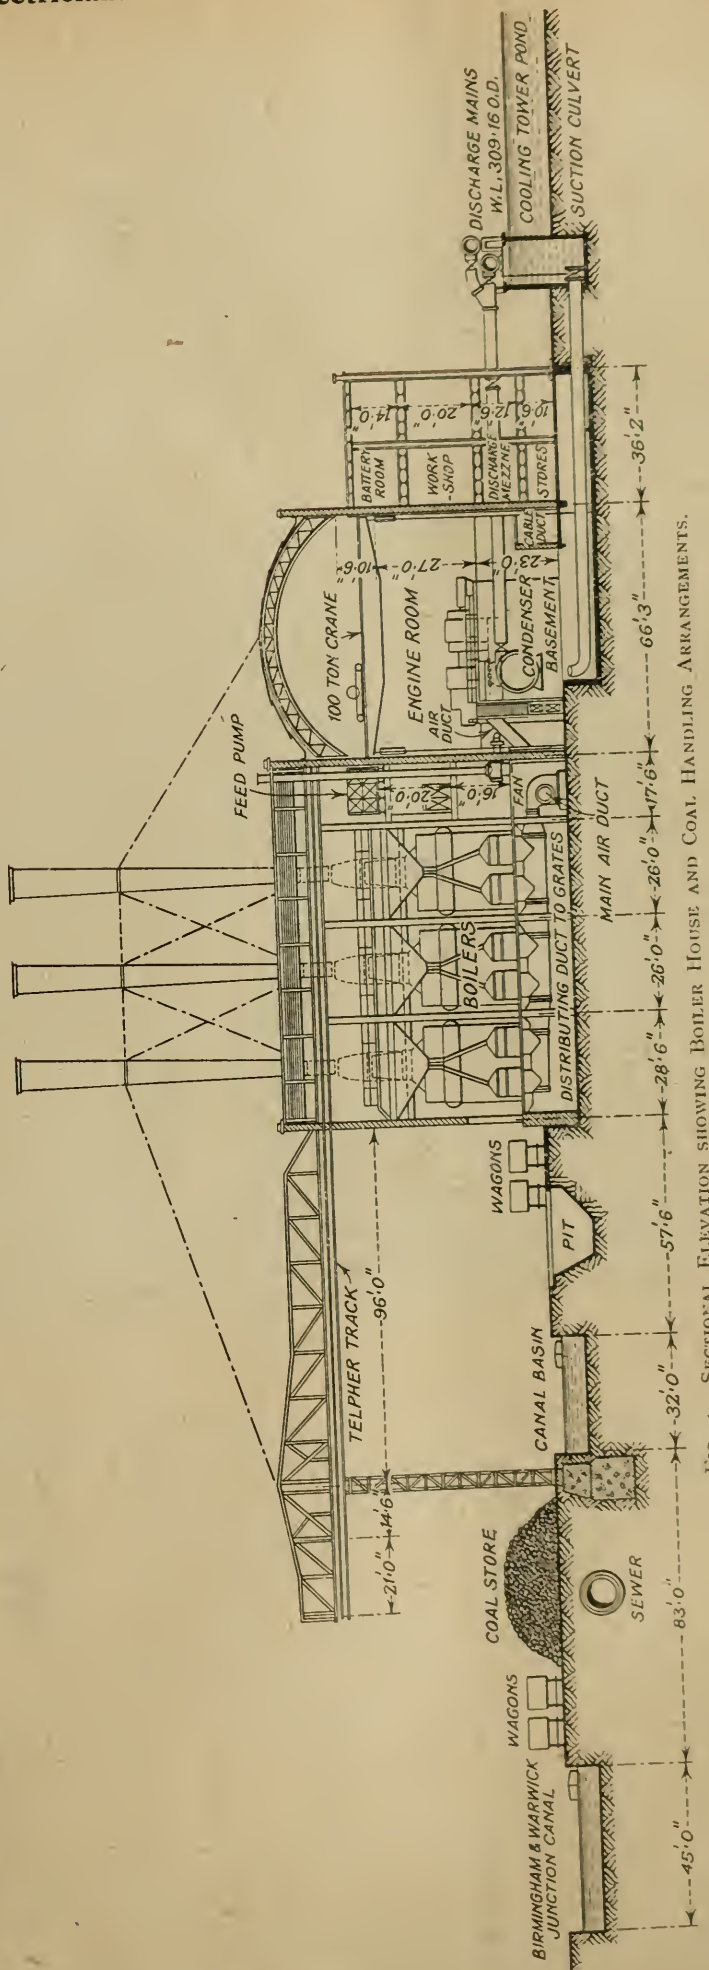

Fig. 4. Sectional Elevation showing Boiler House and Coal Handling Arrangements.

provision is made for superheating the steam to a final temperature of 700° F.

The chain grate stokers have a grate area, per boiler, of 224 sq. ft., are provided with forced draught attachment and, when burning fuel with a calorific value of 9 000 B.Th.U.'s and with a feed inlet temperature to the economiser of 150° F., each steam-raising unit is designed to easily evaporate 35 000 lbs. of water per hour under normal working conditions, with a maximum evaporation, when desired, of 42 000 lbs. of water per hour.

The first four groups of boilers deliver their steam through two 12 in. branches, with a separator in each branch, into a 12 in. cross-over main running parallel with the engine-house. From the cross-over mains 12 in. steam pipes branch off to the turbines.

There are four Weir reciprocating, and two turbine-driven pumps—all driven by steam. The six feed pumps deliver into two 8 in. mains of mild steel throughout: these are made for a working pressure of 375 lb. per sq. in.

shunt wound d.c. generator for the purpose of supplying auxiliary plant requiring d.c. current.

Alternator Construction.

The stator windings are of the bar type, arranged in two layers, in slots of the open type. The slots have openings shaped to accommodate dovetail section keys of impregnated hard wood which hold the windings securely in position. The winding consists of an upper and lower layer of conductors, there being one conductor per layer per slot. The end portions of the windings are supported by deep section bronze wings, well insulated and mounted on brackets on the end flanges.

The ventilation both of the stator and of the rotor is efficiently carried out and thermo-couples, embedded in the stator windings during construction, permit of the temperatures being observed during operation of the machine. The stator windings are subjected to a high potential test of 12 000 V for one minute, both to earth and between phases, before the machine is put into service.

Fig. 5. General View of the Turbine Room at Nechells.

Turbo-Alternators.

The contract for the two turbo-alternators, air filters, condensers, air and circulating pumps, water extraction pumps, feed heaters, evaporators, Venturi meters and atmospheric relief valves, was placed with The British Thomson-Houston Co., who sublet the condensers and other auxiliaries to G. & J. Weir, Ltd., and the air filters to Wm. Grice and Sons.

The two turbo-alternator sets each consist of a high-pressure Curtis horizontal combined-impulse type steam turbine, suitable for working at 300 lbs. pressure (gauge) and 278° F. of super heat (total—700° F.) with 28 in. vacuum, coupled to a 22 500 kVA alternator designed for giving a maximum continuous load as above either at 80 per cent. P.F. or at 66·6 per cent. P.F. at a speed of 1 500 revs. per min.

The normal full load current of each alternator is 2 470 A at 5 250 V when delivering its maximum continuous output, *i.e.*, 22 500 kVA. The instantaneous short circuit current (with full load excitation) will amount to approximately six times normal current.

The exciter for each alternator is mounted on an extension of the shaft and is 125 kW capacity at 220 V. It is capable or giving 20 per cent. more current and voltage than is required at 22 500 kVA at 66·6 per cent. power factor.

On the same shaft with each alternator there is also carried (in combination with the exciter) a 250 kW 440 to 460 V,

The rotor is of the cylindrical non-salient-pole type, with distributed windings. Axial and radial openings are provided through the rotor core at different points, to assist ventilation. The rotor windings are of solid copper strip, edgewise wound, insulated from one another with mica, and from the core by means of mica and fibre troughs. The slot keys are of hard copper and are connected at each end of the rotor to massive bronze end plates, so as to constitute a squirrel cage winding on the rotor. A view of the two sets at present installed is given in Fig. 5.

Air Filters.

The air filters supplied for the two alternators are of William Grice and Sons' manufacture, and are of their twin type "Invincible" wet air filters, each twin unit being capable of dealing with 60 000 cu. ft. of air per minute. Each filter is driven by a 1·75 H.P. direct current motor.

Condenser Details.

The surface condensers are of G. & J. Weir's manufacture, and each deal with 198 000 lbs. of steam per hour, and maintain a vacuum of 28 in. with barometer at 30 in. of mercury, and require 18 500 gallons of circulating water per minute at a temperature of 75° F. The cooling surface is 24 500 sq. ft.

The air pump is of the steam ejector type. Two sets, each at full duty, operate on one condenser. The joint consumption

is 1 130 lb. steam per hour at 150 lbs. pressure. The water circulating pumps are by G. & J. Weir and are in duplicate, one being turbine-driven and the other motor-driven, each set operating at half duty (*i.e.*, 9 500 gallons per minute) the total head is 51 ft. The water extraction pumps are also by G. & J. Weir and are also in duplicate, one being turbine-driven and one motor-driven. Each pump will deal with 198 000 lbs. of condensate per hour. The Weir ejector heater deals with the condensate before it enters the direct contact heater and utilises the exhaust from the air ejector for this purpose.

A Weir direct contact feed water heater imparts the final elevation in temperature to the condensate before it enters the hot-well tank, and utilises for this purpose the exhaust steam from the water extraction pump turbine and the circulating pump turbine, augmented by exhaust steam bled from the L.P. turbine if a higher temperature is desired. The evaporators are each capable of evaporating 7 000 lb. of water per hour when supplied with saturated steam direct from the boilers. The Weir boiler feed pumps, which are in duplicate and of two kinds, draw either direct from the hot well tanks, or alternatively from the condensed water tanks, through the normal, or the emergency, feed suction ranges.

Fig. 6. The Main Switchgear from Above, Showing the Massive Construction.

Step-up Transformers.

Standard 30 000 V Ferranti transformers are used to step up the pressure at Nechells from 5 000 V—the bus-bar pressure—to 30 000 V for transmission to the Summer Lane generating station (where it is stepped down to 5 000 V), and to the Bournville substation on the extreme south-west of the town, where the current is fed into the 5 000 V distributing system.

For this purpose two 10 000 kVA banks of Ferranti single-phase transformers, each having a rating of 3 500 kVA per transformer, with a ratio of 18 500/5 350 V with one spare single-phase unit, are employed at Nechells, one similar 10 000 kVA bank being at Summer Lane, and a 5 000 kVA bank at Bournville. In the last-mentioned case a spare single-phase unit will also be available.

The banks are all star-connected on the high tension side and delta-connected on the low tension side. The technical data for the two types of single-phase transformers are: 5 per cent. tappings are supplied on the L.T. side. The open-circuit watts at 15° C. are 12 500 and 9 000 W for the small and large sizes respectively.

The regulation at unity P.F. is 1·1 per cent. and 0·85 per cent. respectively. Regulation at 0·8 P.F. is 4·0 per cent. and 3·5 per cent. The reactance is 5 per cent. and 4·5 per cent. The efficiency of the large size is 98·5 per cent. at 1/1 load and 98·75 per cent. at half load, and of the small size 98·7 per cent. and 98·6 per cent.

Switchgear.

The contract for the initial installation of high tension switchgear was placed with Reyrolle and Co. The apparatus which will ultimately have to be controlled by the switchgear is as follows: seven 22 500 kVA alternators; six group feeder buses (each for 10 000 kVA; six 30,000 V 10 000 kVA transformers and trunks, to suitable distributing centres—all (including generators, transformers and group feeders) directly off the main bus bars. A view of the gear is given in Fig. 6.

The group feeder switches will each feed through reactances on to feeder bus bars, and from these latter bus bars there will run link mains to other generating stations, and ring main feeders for direct distribution to consumers, and such local supply circuits as are required for the needs of the station itself.

On referring to the skeleton diagram of switchgear connections (Fig. 7) it will be seen that the main bus bars are in duplicate and that all those oil switches which are directly on these bus bars are provided with duplicate isolating switches, by means of which the oil switch may be put selectively on to either set of bus bars.

All the oil switches at present installed on the main bus bars are of the "M" type of Reyrolle gear, which is capable of breaking a short circuit representing momentarily 1 500 000 kVA. The alternator switches are each rated at 3 000 A continuous carrying capacity. There are no potential transformers direct on the main bars (these being placed on the generator side of the generator switches and on the load side of the other switches); thus one source of risk is avoided. The nine switches on the feeder bus bars are of the Reyrolle A.2 draw-out armour clad type, and are automatic and of 500 000 kVA rupturing capacity.

Trunk Connections.

The 30 000 V 10 000 kVA trunk connections between the Nechells permanent station, the Summer Lane station and the Bournville substation are controlled, on the H.T. side, by Reyrolle "R 2" type switches, and are not without interest.

By means of the two 30 000 V 10 000 kVA trunks, the

present Summer Lane generator load will be very greatly eased, by being partly transferred to Nechells, in addition to the easement already afforded by the Nechells Temporary Station (some 20 000 kW).

The main switches ("M" type) for the 30 000 V step-up transformers have a normal rating of 1 500 A.

Group Feeder Switches.

The group feeder switches of 1 500 A capacity control the group feeder single-phase cables leading to the feeder bus bars in which cables are inserted the group feeder reactances each designed to normally carry 1 500 A and absorb 120 V. The reactances are of British Insulated and Helsby Co.'s design and manufacture.

Link and Ring Main Switches.

The "A.2" switches on the group feeder board are of a smaller breaking capacity (500 000 kVA) but are protected by the group reactances and again by the "M" group feeder switches on the main bus bars.

The whole of the foregoing switchgear is provided with electrical and mechanical interlocks in accordance with Reyrolles' standard practice, thus rendering all switches safe to handle.

Control Room Equipment.

The control room is equipped with four main sets of control boards—viz., (*a*) for the main alternators, step up transformer switchgear and the group feeder switchgear; (*b*) for the 5 000 volt ring mains and works supply, also link mains between stations; (*c*) for the low-tension a.c. supply; (*d*) for the d.c. supply. A feature of the main a.c. e.h.t. control board is the presence of an electrically operated diagram of connections of the switchgear. By this diagram the operating engineer can see at a glance the exact position of all the main "M" switches and isolating switches in the station.

Main Cables.

The whole of the main alternator cables between the alternators in the turbine room and the main oil switches in the oil switch room are single-core cables, paper insulated and lead sheathed, and of 0·5 sq. in. sectional area (six cables in parallel to each phase of machine) and were supplied by Callenders Cable and Construction Co.

A cable bridge over the River Rea is intended for the outlet of the 30 to 40 ring main 1 500 kVA feeders, and the two 30 000 V trunks the former of which will eventually carry the distribution supply to the north and east districts of the city: also for any future 30 000 V trunks (feeding the central and south and south-west or other districts).

The six single-core 0·25 sq. in. 30 000 V cables, connecting the high tension windings of the two 10 000 kVA step-up transformers with the switchgear, were supplied by Callenders, as were also the two six-core 0·185 sq. in. 5 000 V split conductor cables, connecting the Nechells "Permanent" station with the Nechells "Temporary" station.

Trunk Feeders to Summer Lane and Bournville.

The trunk feeder cables between Summer Lane and Bournville are for 30 000 V pressure at the delivery end and are of W. T. Henley's manufacture. They have the following characteristics: The cables are of 0·2 sq. in. three-core paper insulated, lead-sheathed, served armoured with a single layer of galvanised steel wires, and again served.

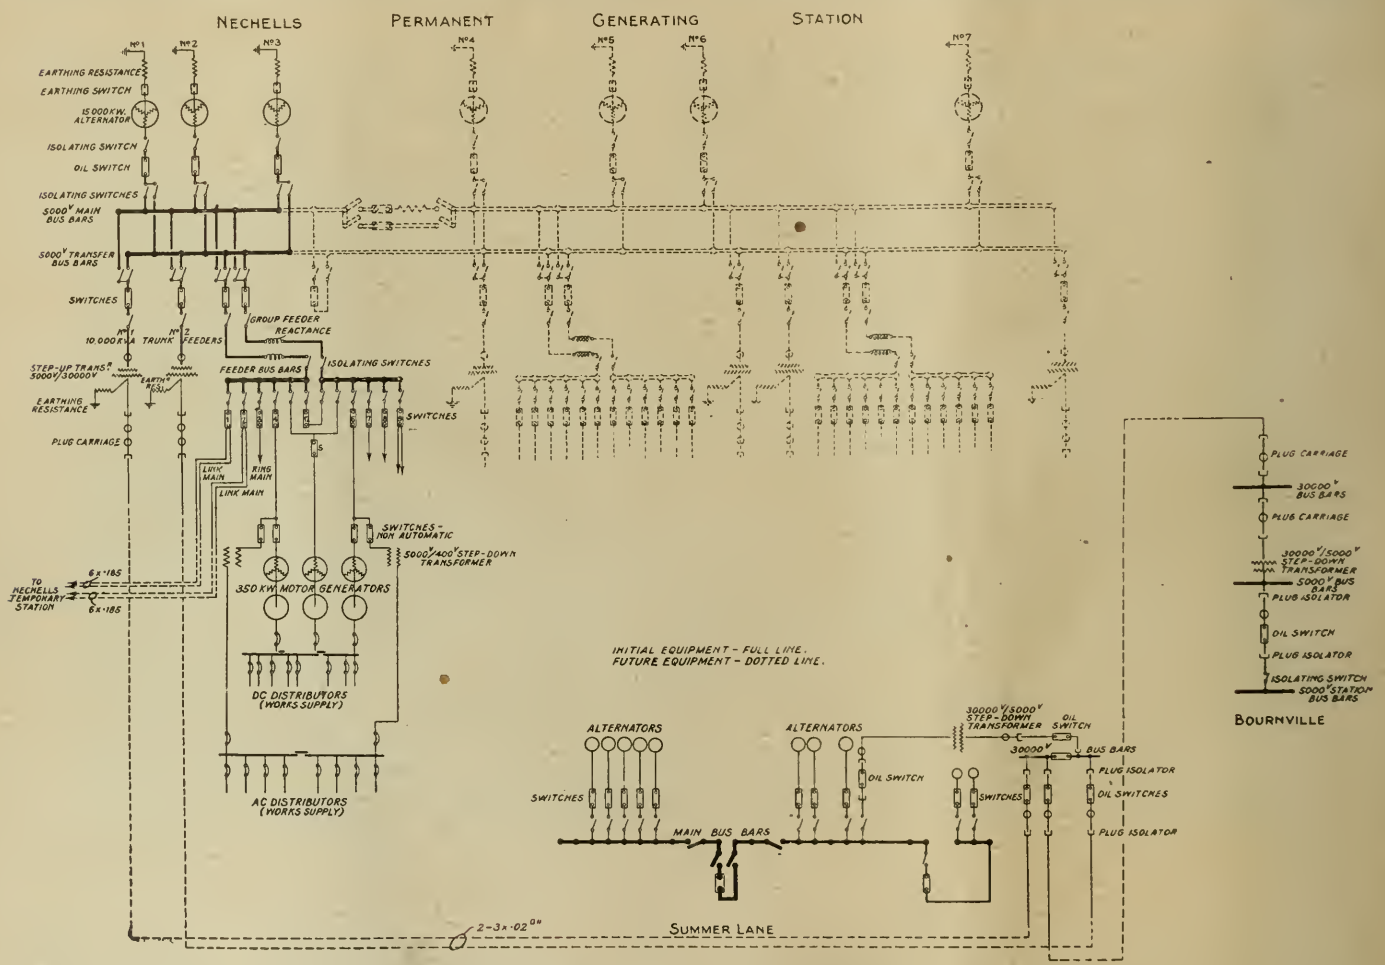

FIG. 7. DIAGRAM OF SWITCHING ARRANGEMENTS AT NECHELLS SHOWING INTERCONNECTION WITH SUMMER LANE AND BOURNVILLE.

We have to thank Mr. R. A. Chattock, city electrical engineer, Birmingham, for giving us an opportunity of inspecting and describing this interesting station.

Electricity Supply in Ayrshire.

An interesting scheme for the formation of a Joint Electricity Board for Ayrshire, consisting of representatives of the County Council and of the Burgh of Kilmarnock, has been put forward. The scheme has been formally approved by the County Council, and as the Electricity Commissioners are said to be favourable, it will probably take definite shape in a short time. In a report, Messrs. Merz and McLellan state that a joint Board would be of great advantage to the county, as it would be able to develop electricity supply on uniform lines under one management for practically the whole county. The County Council will assume responsibility for about £200 000 of capital expenditure, and as soon as the Board is formed an offer will be placed before Ayr Corporation, who will be asked to abandon the Loch Doon scheme and join the Board.

Correspondence.

"MAIN LINE RAILWAY ELECTRIFICATION."

To the Editor of THE ELECTRICIAN.

SIR,—Your leading article on this question in your issue for the 2nd instant has probably an interest for many of your readers besides myself, and I therefore crave the hospitality of your columns for a few notes on same, as well as on Mr. Roger Smith's "impressions," published in the same issue.

I may say I have no axe to grind with reference to the use of single-phase current, and therefore will content myself with saying that it seems unfortunate that the pioneers of this system have so persistently stuck to a frequency as low as 16⅔ periods, whereas I understand that there is no material additional loss in single-phase locomotives, if run at 25 periods. If they had from the beginning pronounced equally favourably for 25 periods as for 16⅔ periods, the probability is that they would have disarmed a good deal of the criticism which has been levelled at the latter, more particularly as regards the impracticability of making generators for this periodicity, and the fact that in London, Birmingham, and Glasgow, a supply at 25 periods could be obtained, would have helped their cause.

No doubt it will be said that the supply in these three cities is three-phase, but I cannot see that there is any insuperable difficulty in taking a three-phase supply off the busbars through step-up transformers, and delivering to substations in which the load may be only *partly* balanced, since the traction load would, in any case, be only a fraction of the total load.

Even in the case of Manchester, which has no 25-period supply on a large scale, I suppose that this would have been forthcoming had there been a demand for it, and it is surely not without significance that the Hell Gate Station, in New York, one of the largest and *very latest* stations in the world, generates equally both 25 and 50 periods, and is laid out with this object.

The other point which I desire to bring forward is that, while in America there has been no particular incentive, with their overhead transmissions, to cut down the frequency, from the point of view of line construction, yet, in this country, where we are almost pledged to *underground* transmission, we are cutting our own throat and precluding the use of the higher voltages, which we shall certainly endeavour to make for, by insisting upon 50 periods. The dielectric hysteresis losses at 50 periods will undoubtedly be rather serious if we ever succeed in getting up to voltages of 100 000 to 150 000 V, and special means will have to be devised for their reduction.

I know that at the moment we are carrying along merrily at 30 000 V, but it must be common knowledge to all those who have looked at all into the question of main line electrification, or of the interlinking of important cities or areas, that 30 000 V is terribly uneconomical as compared with what we might do if able to run up to 100 000 V.

Mr. Roger Smith states in his article that "with three-phase transmission it is doubtful if one generating station could economically feed to a greater radius than 25 miles." I agree that it is doubtful, *if we are limited to 30 000 V*, but I do not think it is at all impracticable to consider 50 miles if the voltage could be raised to 100 000. Hence, if this figure could be attained, the arguments which Mr. Roger Smith deduces as to the steam generating station, for the railway load alone, being too small, would be considerably weakened —if not cancelled.

The fact that 25 periods has proved no disqualification to the Glasgow and Birmingham Corporations, and the Clyde Valley Co., obtaining a very large motor load proves that there is still a great deal to be said for 25 periods as a general proposition, and the importance of being able to extend the area of operations of those stations which are *really* able to generate economically may well prove to be worth as much as a slightly reduced cost on industrial motors and on transformers.—I am, etc.,

SIGMA.

THE REMUNERATION OF TECHNICAL ENGINEERS.

To the Editor of THE ELECTRICIAN.

SIR,—I would like to draw the attention of technical engineers to the notable victory just gained by the strongest and closest Union in the world, viz., The British Medical Association. I claim that in forcing the Manchester City Council to recommend the payment of £1 700 to £2 000 per annum to their Health Officer this Association has given a wonderful lead to other unions of technical men. It is noteworthy that there have been no fireworks—no processions—very little newspaper publicity—simply a dignified protest at the low figure offered (£1 500 per annum) and then the ban.

I would like you to ask Technical Engineers what would happen if a similar situation arose in the appointment of an engineer. Just an undignified rush for the position without any reference to any representative body, and with very little consideration as to whether the position was worth more or not. And why?—Bad times. Nonsense! In times of full shops and plenty there would still be the same rush for any position offering £1 500 per annum. Yet engineers are quite as necessary as—perhaps more necessary to the common good than—the doctors. The reason is simple. There is no representative body to apply to. We, as technical engineers, are not strong enough to protest against low salaries—disgracefully low in many cases. The moulders are—members of the railway unions are—and yet we consider ourselves intelligent men. Yea, even the salt of the earth—some of us.

Surely the one instance I have cited shows the necessity of getting together and giving our society the power to assert itself and to exert its power in its members' interests, as was done by the B.M.A.

The only way this can be done is by wholehearted co-operation among technical engineers, through the medium of a society such as the Society of Technical Engineers.

TECHNICAL.

Automatic Train Stops.

The REPORT OF THE COMMITTEE appointed by the Ministry of Transport in October, 1920, to inquire into automatic train control and to examine devices under trial was published on Tuesday.

The Committee find that there is a *prima facie* case for automatic train control on British railways, and that the method most likely to suit existing conditions on British railways should supplement rather than replace existing block telegraph and signalling systems, and comprise (*a*) automatic train-stop, located at or near selected stop-signals, which shall, in the event of a train passing such signals when they indicate danger, bring the train to a standstill; (*b*) automatic warning control at distance signals, and at other places where danger from too high a speed may be anticipated.

The Committee have drawn up a series of conditions with which any acceptable system of automatic train control should generally comply. The estimated cost for the full scheme on passenger routes on which there are two or more lines in existence is:—First cost, £4 660 000; annual charge, £407 000. The Committee recommend the immediate formation by railway companies of a committee of experts to standardise track and locomotive apparatus, having regard to differences in structural and loading gauges.

The report is unfavourable to the adoption of the continuous type of control, which aims at entire and constant protection of a train at all stages. With regard to localised (intermittent) control, the Committee state that the contact type of apparatus has proved reliable after many years' operation under working conditions, and capable of withstanding satisfactorily the effects of high-speed traffic, but they cannot recommend it for British conditions.

London Electricity Supply.

It will be remembered that the Electricity Commissioners in announcing their decision on the scheme submitted at the LONDON INQUIRY, stated that they concurred generally in the technical proposals for the first stage of development, but that they differed from the promoters on the proposals for the second stage. By the alternative proposals of the Commissioners for the later stage, it was estimated to bring about "an annual saving of upwards of £1 000 000 (15 per cent.) and 10 per cent. in fuel, with all the advantages derivable from a capital station, such as availability for large railway or other supplies in bulk on favourable rates." Subsequent correspondence took place between the Commissioners and the Engineering Committee, with the result that the Commissioners have agreed that a substantial modification must be made in the figures for comparative purposes with a consequent substantial reduction in the estimated saving between the Commissioners' proposals and those of the promoters.

The Commissioners are of opinion that in fairness to the Engineering Committee this should be made known to the promoters. They, nevertheless, adhere to their conclusion that their alternative proposal to supplement existing stations during the *second* stage by capital stations (if the rate of growth estimated by the promoters is realised) will result in substantial economy compared with a further comprehensive extension of existing stations. The impression which appears to have arisen that the Commissioners desire to fetter the engineers of the future Joint Authority by proposals made now for dealing with the demands during the second stage of development, is unwarranted. The consent given by the Commissioners to the County of London Electric Supply Co. to construct a station at Barking with an installation of 100 000 kW. is "for the needs of the County Co.'s own statutory obligations only." Whether or not that station will hereafter be made a capital station for wider purposes is a matter for consideration by the future Joint Authority in the first instance and for subsequent approval by the Commissioners.

The "Empire" High Tension Fuse.

A considerable amount of thought has recently been given to the problem of limiting the area of disturbance caused by a short-circuit on a high tension network. As a result much protective apparatus has been devised, and schemes, both complicated and simple, have been evolved with the object of ensuring that the faulty portion shall be cut out with accuracy and speed, and that the sound portions shall be left in circuit. One of the ways of doing this, which at least has the merit of simplicity, is that well-known device, the fuse, of course specially designed and constructed for the conditions which are present on high tension networks.

"Empire" Fuse.

A fuse of this kind which seems to fulfil all the essentials is the "Empire" S. and C. high tension fuse. This, we are informed, is the result of many years actual experience under working conditions in the United States, and we are therefore interested to learn that the British rights of manufacture have been exclusively secured by Electric Control, Ltd.

Constructional Details.

As our illustrations show, the construction of the "Empire" S. and C. high tension fuse is quite simple. It consists of a strong glass tube of the same strength and quality as used for high pressure steam gauges. Inside the tube there is a spring, one end of which is connected to a brass ferrule, the other end being fixed to the fuse wire, which passes through a cork and is connected to another short wire fixed to the top ferrule.

Between the cork and the spring, and fixed to the latter, is a funnel-shaped liquid director. The glass tube is filled with a non-inflammable liquid which has a dielectric strength of 250 000 V per in.

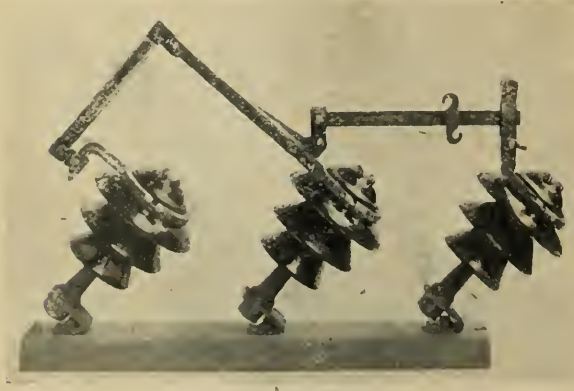
Instead of the ferrule type of contact, the fuses for the larger currents are fitted with knife blade contacts as shown in Fig. 2.

Operation of the Fuse.

The operation of the fuse is as follows: The melting of the fuse wire releases the spring, which instantaneously contracts, and thus introduces a large gap into the circuit. Simultaneously the liquid extinguishes the arc and thus interrupts the flow of current, the rapidity of its action being accelerated by the liquid director, which is drawn down by the spring, and thus causes the liquid to be forced directly on to the moving terminal. The length of the fuse depends on the voltage, and the size of the different parts on its continuous current capacity.

The large gap and high dielectric strength of the liquid gives, it is claimed, a factor of safety equivalent to several hundred thousand volts.

It can be seen at a glance when an "Empire" S. and C. fuse has blown, owing to the closed spring leaving a large clear space. Fuses



Knife Blade Contacts.

mounted on outdoor pole installations can easily be detected by the linesman from the ground, which, in addition to saving a great deal of time, reduces the danger to life to a minimum.

Tests show that these fuses will clear short circuits without causing the circuit breakers to trip. To take a particular example, on the A fuse successfully opened a short circuit of 1 170 A in 0·013 sec. Other important points are that the fuses always open on the zero point of the current curve and no danger has been experienced or anticipated from the glass container breaking.

Electric Power Supply in East Norway.

H.M. Minister at Christiania has informed the Department of Overseas Trade that the Commission, appointed by the Storting in 1918 to investigate the question of a National Scheme for the supply of electricity to the whole of Norway, has agreed on temporary recommendations for the power supply of East Norway. The recommendations have not been published, but in a *communique* to the Press, it is stated that the Committee are of opinion that to furnish an efficient supply of electricity to East Norway the district must be treated as a unit. The main source of power for the district will be the Nore power station, of which the construction should be continued. In the meantime, the Raanaasfos power station has been finished, but is not under full load. The Mrkfos-Solbergfos scheme will be completed in 1924, and will yield about 40 000 kW. There will be about 20 000 kW further available from the Rjukan station.

The new power is said to be comparatively expensive. The economic situation indicates that the increase in the consumption of power will not be very great during the next few years. The level of prices is falling and large constructional operations which can be postponed should not be pressed, but, in view of the prevailing unemployment, work should be continued on the Numodal Railway and on the Nore scheme, in which wages form the chief expense, while orders for pipe lines and machinery as well as the construction of the power station should be postponed. Considerable amounts of power can, however, be acquired at comparatively little cost by the regulation of the Glommon and Numedalslaagen operations, which also call for a comparatively large staff of men, but do not require so much in the way of material.

The power not sold in the district should be distributed by the State to convenient places within the various counties, and should be offered at a price of Kr. 150 per kW per year, decreasing to Kr. 125 as the regulation of the Glommen progresses. When the Nore power station comes into use the price should be reduced to the tarifi in force for that station. The price proposed does not apply to the Rjukan power. As, however, the Rjukan power line will, in the view of the Commission, retain a permanent value, this installation need not be written off as quickly as was the original assumption. It is also proposed that the price for this power when delivered at Kongsberg should be reduced to Kr. 125 per annum.

German Scientific Instruments.

Final evidence was taken on Monday by the Board of Trade Committee which is inquiring into the request of British manufacturers of optical and other scientific instruments for protection under the Safeguarding of Industries (Part II.) against German competition.

Major A. G. Church, general secretary of the National Union of Scientific Workers, said there was great difficulty in obtaining British scientific instruments of the more uncommon type. Research and teaching institutions considered that they were being badly treated under the Act, and he quoted Sir J. J. Thomson in support of the statement that Part I. had greatly increased the difficulties of research. Witness regarded research as a key industry which should be entitled to protection against the present Act. He gave particulars of various institutions in which researches had been delayed or abandoned.

The results of the Act were: Increased costs, waste of time on preparation of materials which would be more profitably spent on research, and spoilage of work owing to restrictions put upon importation of glass and laboratory ware of the requisite standard and quality. The Act had been characterised as a "nasty German device for ruining British industry." Scientific workers feared that British manufacturers did not realise the essential importance of improving the quality of their wares, and protection against outside competition would inevitably tend to things being left much as they are.

Mr. S. Segal said that since the introduction of the 33⅓ duty his business of scientific instrument importer had dropped by 60 to 70 per cent. The production of cheap-grade opera and field glasses was almost totally a French industry, and the trade in those had disappeared since the duty had been levied.

Sir Arthur Colefax, K.C. (for the applicants), announced that it was their intention to withdraw the claim with respect to electrical apparatus.

Mr. Inskip, K.C., M.P., submitted on behalf of the opposing firms that the present conditions in the industry were largely due to temporary post-war influences. Some manufacturers had over-produced during the post-war boom and the policy had proved disastrous when the slump came. The evidence given did not establish the points which the Committee had been asked to consider.

Sir Arthur Colefax submitted that German catalogue prices of many firms were purely fictitious. By reason of the depreciated currency with which the low cost of manufacture was bound up German goods were sold here at prices with which we could not compete. He did not believe research would suffer to any appreciable extent, and, on the other hand, national interests and employment might be assisted.

Railway Companies' Power Supplies.

The inquiry by the ELECTRICITY COMMISSIONERS into the proposals of the S.E. and C. Railway Companies and the West Kent Electric Power Company to erect generating stations and supply the electrical energy for working certain of the lines of the S.E. and C. Companies, and also an offer of the County of London Electric Supply Company to supply the railway companies' requirements from their proposed Barking station was concluded on the 15th inst.

Mr. R. H. HOUGHTON, chief electrical engineer to the L.B. and S.C. Railway Company, said the company had 22·4 route miles or 69·6 single track miles of their system electrified. The annual consumption was 16 080 000 units, purchased from the London Electric Supply Corporation. The electrification of another small section of 5·8 route miles, or 25·6 single track miles was in hand. A scheme had been prepared for the electrification of the whole suburban system, which included 101 route miles, or 400 single track miles. The electrical energy required was over 200 million units per annum and the maximum demand would be 63 000 kW. The supply at present was at 6 700 V. If the complete suburban scheme were carried out the voltage would be changed to 11 000. The electrification at present went to Selhurst, but the company had a scheme before the Ministry of Transport which would go as far as Coulsdon. There was also a scheme for electrifying to Cheam. They had found the supply from the London Electric Supply Corporation perfectly satisfactory.

County of London Company's Offer.

The Hon. EVAN CHARTERIS (for the County of London Electric Supply Co.) read the offer of the company to the South-Eastern Railway Company. The County Company would supply electrical energy to the South-Eastern Company at a periodicity of 50 and a pressure of 33 000 V, the supply to be sufficient to deal with a railway load of 30 000 kW; the County Company would pay the increased cost of motor generators as compared with rotary converters and transformers, the full supply to be available within three years from June 30, 1922. The South-Eastern Company would pay for the supply on a fixed annual rental equal to 7·4 per cent. (4·5 per cent. interest, plus 2·9 per cent depreciation) on the estimated capital cost to the South-Eastern Company of the Angerstein's Wharf station and the transmission mains from that station, or such other rate of interest and depreciation as the Commissioners might fix.

The South-Eastern Company would pay the actual local rates paid by the County Company in respect of 45 000 kW of plant at Barking, and also the actual local rates incurred by the County Company in transmission mains in respect of a capital value of £65 000; the South-Eastern Company to pay as a running charge the cost per unit other than the fuel cost estimated by the South-Eastern Company's witnesses for operating their station, with a minimum equivalent to 25 per cent. of the said operating and maintenance cost for a load of 29 000 kW; the South-Eastern Company to pay as a fuel charge the actual cost of fuel incurred by the County Company on the basis of 20 000 B.Th.U. per unit sent out from Barking at 33 000 V; the County Company would allow a rebate on the fuel cost of half the difference between the coal consumption per unit sent out from Barking at 33 000 V and 20 000 B.Th.U.; as a further rebate the County Company would allow 4 per cent. on the running charges and coal bill on account of the decreased operating efficiency of motor generators; for all extensions of the South-Eastern Railway Company's electrification the County Company undertake to supply electrical energy on similar lines as above, and the South-Eastern Company agree to take such additional supply. There would be arbitration, strike, coal and land clauses, and the period of agreement would be for a minimum of 25 years.

Economy of Combined Stations.

Mr. C. H. MERZ said there was an enormous saving of expenditure on distribution in the case of a combined station. The creation of separate stations for railway supply was a retrograde step. If a separate station were erected for railway purposes consideration should be given to the question how far it could eventually be brought into a general system. The proposed S.E. and C. station would be on a wrong site to supply an industrial load and it would have the wrong periodicity. He estimated that the result of supplying the railway demand from a station for combined purposes would be a saving of £483 000 in capital expenditure, and there would also be considerable saving in operating cost. The saving would be some £19 000 per annum, apart from fuel. In a general system there would be a gradual increase in coal economy by the introduction of improved plant, whereas a railway power station would not gain by improvements in the electrical industry until its original plant was written off. Suppose one took a ten years' load on a big combined system, and every year 50 000 kW of plant were added to the system, ten years hence the system would have grown to 250 000 kW, the last 50 000 kW installed might be 15 or 20 per cent. more efficient than the first 50 000 kW, and the last 50 000 kW would probably turn out 40 per cent. of the total output. On the North-East Coast there were about 300 000 kW of plant, and not more than 120 000 kW was of the most economical type. The railway company had no opportunity of improving unless they extended the electrification of their line. In the case of the North-Eastern Railway, the railway company got the benefit of improvements. Half the total charge for energy was based on the coal costs. A similar arrangement would be made between the County of London Company and the South-Eastern. From the technical point of view the Belvedere site was a good one, but a connection between the north and south sides of the river would have to be made sooner or later, and it would be cheaper to supply from the Barking station.

Engineer's Evidence.

The County of London Company were some months ahead of the other parties from an engineering point of view. It was proposed to generate at Barking at 50 cycles, but they would supply to a railway company at the periodicity they wanted. He was not sure that the County Company would not make more money by supplying at 25 cycles, but from the point of view of the general utility for London 25 cycles was wrong. The life of generating plant came to an end in 15 or 20 years, and the system could then be altered, but that did not apply to transmission and distribution. When transformers, motors, motor generators and rotary converters were put down at a certain periodicity it was almost impossible to change. He thought 25 cycles would be inconvenient for the railway company as it would not be the right periodicity for lighting and industrial purposes along the company's route. There was a considerable saving in cost of transformers. He thought it was essential that 50 periods should be standardised for the London district. In the offer made by the County Company the cost of motor generators, the extra cost of transmission and the construction of a tunnel under the river had been taken into account. The company had a demand of 30 000 kW, and 45 000 kW was a conservative estimate of the industrial demand in 1926. To deal with that and a railway load of 30 000 kW the most economical way would be to install four 35 000 kW turbo-alternator sets.

The Barking Station.

The Commissioners had only authorised 100 000 kW of plant at Barking. The 35 000 kW sets would be tandem sets—with two generators. If the company were restricted to 100 000 kW he would advise that four 25 000 kW sets should be installed. The actual saving which he estimated on the power station, compared with the railway company's figures, was £625 000, and after deducting transmission and £16 000 for extra cost of motor generators, the saving would be £483 000. He was only crediting the South Eastern with three cables. The reserve cables would be available for their supply as well as for general supply. Pooling the reserve meant a saving in capital cost. Each cable would carry 16 000 kVA. The use of 50 cycles had a bearing on the cost of the cable network as the cables used to supply the railway could be interchanged with the other cables for the County Company's own transmission. It might be possible in a large station to effect considerable economy by low temperature carbonisation of a portion of the coal. A commercial plant for that purpose was nearing completion on the site of the Dunston power station.

Sir JOHN SNELL and Sir HARRY HAWARD expressed the opinion that the offer of the County of London Company should be translated into a definite charge per unit so as to make it comparable with the South-Eastern cost and the West Kent figures. Sir Harry also said it should be shown whether the proposed charge was an economical charge from the point of view of the County Company and what bearing it had on the amount which a Joint Authority would have to pay to the company when it took over the station.

Mr. CHARTERIS promised that figures showing the capital and running cost to the County Company should be supplied to the Commissioners.

Replying to a suggestion by Mr. CLODE that the allowances made in his figures did not cover all the extra cost to the County Company, Mr. Merz said there would be no additional switchgear—the switchgear would be rather simpler. The County Company were prepared to indemnify the railway company in the event of current not being ready when the line was equipped for electric working.

Replying to Sir JOHN SNELL, witness said the County Company's offer amounted to about 0·481d. per unit in the first stage, and after that stage they would share with the railway company the benefit of improvements in regard to consumption of fuel.

Position of London Companies.

Mr. W. F. FLADGATE, chairman of the Charing Cross, West End and City Electricity Supply Co. and of the London (Electricity) Joint Committee, said the engineering scheme put before the Commissioners last year had never been departed from as far as the nine companies comprising the Joint Committee were concerned. It was always contemplated that they would get the railway load. They contemplated the erection of a power station in due course, but not in the first stage unless they had the railway load. The London Electric Supply Corporation could supply 30 000 kW to the S.E. and C. Companies by extending their present station, but a new station would be required to supply the S.E. and C. ultimate load and the L.B. and S.C. load. They had not yet been informed by the L.B. and S.C. that they wanted the additional supply. He thought the London companies should be allowed to group themselves into one joint electricity authority. The improvement of the supply in London could then be commenced at once. He saw no difficulty in the supply being given to the railway companies by June, 1925, by either the West Kent, the County of London or the London Electric Supply Corporation. He was not at the moment

prepared to say his companies could do the business cheaper than the West Kent or the County of London Company.

Gas Company Claims Protection.

Mr. Seager Berry (for the South Metropolitan Gas Company) said certain sections of the Kent Electrical Power Act, 1906, the Electric Lighting Act, 1909, and the London Electric Supply Act, 1908, provided that the railway companies (unless a Special Order were obtained) could only use electricity taken from an authorised undertaker for traction and carriage lighting. If the S.E. and C. Companies got the powers they asked for they could use their energy for any purpose, and they could take from the gas company the best customers amongst the railway companies' tenants. He asked that a proviso to prevent this should be imposed if the railways took power from an outside undertaker.

After the conclusion of the evidence, counsel for the various parties addressed the Commissioners. For the Conference of Local Authorities, Mr. Turner asked for the insertion of a purchase clause should one of the companies obtain the right of supply.

Concluding Proceedings.

Mr. Craig Henderson, on behalf of London County Council, said the West Kent Company's application was really an application by the parent company, the South Metropolitan Electric Light and Power Company. If the station was authorised the latter company would transfer its main source of supply to Belvedere, which would have a serious effect on the position of the purchasing authority in London. There would be nothing to prevent the West Kent Company supplying the South Metropolitan Company with current for distribution in the London area. The Commissioners had constituted a certain electricity district, which included the County of London, and their scheme was that it should be administered by a Joint Authority, representing all interests, municipal and company. The West Kent Company's proposal undermined those foundations, and if it were carried through the L.C.C. would have to reconsider their position as the purchasing authority. He asserted the County of London Company and the West Kent Company were allied companies, in the sense that Sir Harry Renwick was a director of both, and the County Company made their offer at the eleventh hour when they thought the West Kent Company's case was falling. The L.C.C. favoured the railway company's application in preference to the other schemes, although they recognised the desirability of supplying for traction and other purposes from a combined station.

Mr. Charteris (for the County of London Company) contended that under section 11 of the 1919 Act the Commissioners could give consent to the County Company to increase their Barking station to 140 000 kW. The Company's 1905 Act gave power to supply energy for traction.

Mr. Tyldesley Jones (for the West Kent Company) said the company were not seeking to take away any railway load from a Joint Authority or any London authorised undertaker, because none of them (with the exception of the County Company) had offered to cater for it. The main point was, could they supply at a cheaper price than the South-Eastern Company could supply themselves? The West Kent Company's offer was to supply at 0·575d. in the initial stage, subject to a rebate clause and deductions under the efficiency clause. That was less than the cost at which the railway company could generate and when they reached the stage when the maximum demand was 29 000 k.W., the output of 89 million units and the load factor 35, the price would be 0·555d. He was advised that the railway companies' estimates were too low. It was dangerous to put the transformers in the turbine house and proper provision for their housing would increase the expenditure; also the interest of 3 per cent. on capital during construction was too low.

Demand for Separate Traction Station.

Mr. Clode (for the S.E. and C. Companies) said there was every expectation of combining the S.E. and C. and the L.B. and S.C. supplies and also assisting the general requirements by supplying surplus energy. Until the present inquiry not a single offer had been made of a supply at a price as low as the cost at which the railway companies could supply themselves, and they could not see that the prices now quoted were any lower. He asked the Commissioners to use their discretion and approve the railway companies' scheme even if, in their judgment, either of the other supplies offered were very slightly lower in price. There would be considerable reductions in cost if the railway companies supplied surplus energy. If they supplied 10 million surplus units, the cost of the railway power became 0·361d. at Lewisham, if they supplied 20 million units it was 0·354d., and if 40 million, 0·339d. If anything had to be added to the railway companies' estimates for the site of the station it could only be £7 000, as the whole of the 39 acres (of which the station would occupy 20) cost £13 500. His figure of 0·339d. per unit compared with the West Kent figure of 0·493d. if the thermal efficiencies were levelled up. The South-Eastern and Chatham were on the eve of a great change of their system, and he did not see how they could hand themselves over to the joint stock company and the private company who were putting forward the Belvedere proposal. Why should they place themselves in their hands for 60 years? What was the advantage of putting the generating station and the electrification in two different hands? In the case of the County of London Company he did not know what figure he could take for comparison, but he asked the Commissioners to approve the railway companies' proposals which would not disturb in any way the scheme for the Joint Authority in London.

Electricity Supply in Liverpool.

Last week an inquiry was held into the application of Liverpool City Council for a Special Order to authorise the extension of their electricity supply area to Bootle, Waterloo-with-Seaforth, Litherland and Great Crosby. The inquiry lasted seven hours and was held by Col. T. C. Ekin.

The Deputy Town Clerk (Mr. E. W. Pierce) appeared for the Corporation, and the Town Clerk of Bootle and the clerks of the other three authorities and of the Mersey Docks Board also supported the application. There was some opposition by dissenting Bootle ratepayers; and applications were made by Mr. J. Lias, for the Municipal Employees' Council; and Mr. W. Arthur Jones, for the Electric Power Engineers' Association.

In opening the case for the Corporation, Mr. Pierce said the proposed order would extend the Liverpool area of supply from 21 219 acres to 27 313 acres and there would be an additional population of 136 000. When the Corporation acquired the electricity undertaking in 1896, the city consumption was 1½ million units, and that had grown to 88 million units. After negotiations an agreement had been made with Bootle, an important borough to the north of the city, and evidence would be given to show that the agreement was very fair to Bootle. Litherland had obtained a Provisional Order, expiring in 1942, and that order, which had been transferred to Bootle, would be extended to 42 years. The company which supplied Waterloo-with-Seaforth and Great Crosby had an order with 16 years to run. The company had been bought out at the amount of the actual paid-up capital, and its order extended to 42 years. The Mersey Docks and Harbour Board had given unqualified approval to the application. With regard to the opposition from workers, the employés at both stations would be absorbed at not less than their present wages.

Mr. Harold Dickinson, city electrical engineer, gave technical details of the scheme. He said the £7 500 per year paid to Bootle could be applied either in relief of rates or in reduction of the charge to electricity consumers. Liverpool would not make a net profit of £5 000 yearly by the arrangement. The agreement with Bootle was influenced by the fact that Bootle was threatening Liverpool with an action because Liverpool had extended its supply into the Bootle area through the Dock Board mains.

Advantages of Unified Supply.

Mr. Frank C. Wilson, chairman of the Liverpool Corporation Electricity Committee and of the conference of Merseyside electricity authorities, said he was convinced that all Bootle consumers would reap an advantage by taking supply from Liverpool. Bootle was protected as to the prices of electricity for lighting and other services. The whole port would gain by an economical supply of electricity to the entire dock estate.

Mr. James Scott, chairman of the Bootle Electricity Committee, considered the Liverpool and Bootle district an ideal area for the development of manufactures and commerce by electric energy. The fixed subsidy of £7 500 annually was preferable to a subsidy varying according to profit and loss. Waterloo and Crosby would gain through the proposed Liverpool supply. Liverpool could make £4 000 a year out of the Bootle supply more than Bootle could make.

At the close of Liverpool's case, Mr. Lias and Mr. W. Arthur Jones submitted in writing proposed clauses for the protection of the workmen and staff at the Bootle and Waterloo electricity works.

The legal representative of the Bootle objectors having addressed the Inspector, Mr. Pierce replied for Liverpool and said the amalgamation of the Liverpool and Bootle electricity undertakings and the payment by Liverpool to Bootle of £7 500 yearly, were both "for all time." None of the manual workers would suffer in wages, but would gain in prospects.

Electricians' Tools.

The "Enox" saw frames shown in the accompanying illustrations are among the latest products of Frys (London) Ltd.

Fig. 1 shows a frame suitable for bench use in works where ordinarily the bulk of the material would be cut in a machine.

Fig. 1

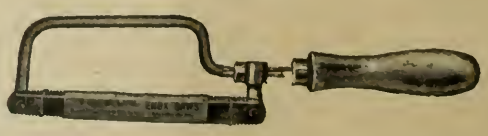


Fig. 2

This frame cuts material up to 1 in. It is also useful for electricians to carry in their tool kits.

The frame shown in Fig. 2 can be used in the same way as that in Fig. 1, but has the additional advantage of being a handy size for small work. The firm have called it the "Tool Makers' Frame," as with it dies can be cut up more quickly than in the usual way.

Electrical Situation in Uruguay.

An interesting article by Mr. H. D. Bindon, A.M.I.E.E., on Uruguay as a market for electrical goods, appears in a recent issue of the Journal of the British Chamber of Commerce in Uruguay. The country is mainly agricultural, and there is not, apart from the requirements of the electricity undertakings of the cities and provincial towns, much demand for big power units or for motors with a rating above 100 h.p. The generating plant of the city of Montevideo is state owned; electricity is generated at one main steam station near the water's edge by turbo-alternators, and three-phase (50 cycle) h.t. current is delivered by underground cables to sub-stations throughout the city, supply being given at 220 V for light and power. The two Montevideo tramway companies (Sociedad Comercial de Montevideo, a British-owned company, and Compañia Transatlantica, a Spanish company of German origin) have their own d. c. generating stations.

Prohibitive British Prices.

In the provinces, except in a few isolated cases, alternating current at 220 V is supplied. There is little or no water power in the Republic, but steam and oil engines are much used. Hitherto, few electrical goods of British manufacture have been sold in the country, as the prices were too high, but large quantities of wiring materials have come from Germany, Italy and the United States. The flexible lamp cords and insulated wire are in many cases of an inferior quality, and for ordinary house lighting most of the cord and insulated wire sold is rated as 500 V. A high percentage of house wiring is done by means of flexible cord strung on small porcelain insulators. Tumbler switches are unknown (and are considered unsafe by municipal authorities, etc.). Practically the only type of switch adopted is the "Hart" snap switch, of American manufacture. For steel conduit wiring, until recently nearly all fuse and jointing boxes were of wood impregnated with tar or suchlike, and no attention was paid to the earthing of conduit or fittings. On the other hand, wood casing is strictly prohibited, but Bergman insulated brass or tin tubing is used extensively.

With regard to house lighting fittings, there is a demand, since the introduction of period decoration, for corresponding fittings, highly ornamental brass fittings being used. These are largely manufactured in South America from the original French patterns, and the home manufacturer cannot compete with these cheaply made articles, though he scores in the higher class fitting, finished in oxidised silver or copper, etc. Highly decorative glassware is also much used in conjunction with lighting fittings. The screw type of lamp-socket is commonly used; in fact, outside railway and tramway companies the bayonet type of socket is unknown.

Demand for Small Domestic Appliances.

While electric cooking is not considered very much, such articles as portable stoves, coffee pots, tea kettles, toasters, irons, etc., are much in demand. These articles mainly come from the United States and are not only unique in design but are well made, with provision for the easy renewal of heating elements. Mr. Bindon states that of late the home manufactured articles of this class are not only very expensive but of poor construction, coupled in many cases with antiquated ideas. Only recently an important home manufacturer sent out, amongst other things, a large quantity of electric irons, badly nickel-plated, fitted with non-heat resisting handles of composite material, combined with the old type of heating element built of round wire mounted on micanite instead of pure mica. These irons were circulated by the firm's representative amongst several of the most important local electrical supply shops, with the result that the manufacturer soon lost his reputation in Uruguay, and it will be more difficult for him to get his goods into the market in future. Many home manufacturers, who are anxious to get a footing in the country, will persist in sending out the wrong class of goods, and in many cases catalogues printed in English which the native buyer does not understand.

All incandescent lamps come from Holland, Germany or the United States, and Mr. Bindon inquires why we cannot manufacture a lamp suitable for export, and if not, why not? He suggests that we are too conservative in many of our ideas and that we forget that what is suitable for the requirements of the Northern Hemisphere may not be suitable for the Latin-American Republics.

Wiring Regulations in Quebec.

In the Province of Quebec, a strong REACTION seems to have set in AGAINST SLIP-SHOD WIRING METHODS and ineffective inspection of installations. As a result of representations by the Electrical Co-operative Association it has been decided to allow in future only a single service entrance for any one class of electricity service in new public buildings. The rule, as well as other regulations, have been adopted by the Fire Underwriters' Association, and became effective on the 1st inst. In cases where a building is already wired and additional apparatus is installed arrangements must be made to connect the new work to the existing service, increasing the capacity of this if necessary. If the present service does not comply with the specifications a new service of sufficient capacity for both the old and the new loads should be installed.

The new regulations dealing with earthing and general installation work are somewhat similar to British practice, as exemplified in the Wiring Rules of the I.E.E., the Phœnix Fire Office, etc.

Gas Wail from Birmingham.

The Birmingham Gas Committee were recently asked to report on the possibility of (*a*) narrowing the present margin between prices charged to small and large consumers and (*b*) charging the same price for gas, irrespective of the purposes for which it might be used. In a long report the Committee state that there is every justification for differential charging, and point out that after Midsummer, 1915, the price to large consumers was advanced more rapidly than to small consumers. In future revisions of prices the difference would be narrowed so that the increases over 1915 would become more nearly equalised.

There was a two-fold justification for the lower rates granted for gas supplied for power and industrial heating, viz. (1) the great advantage gained by having a regular day load, summer and winter alike, and (2) the more important factor of competition by electricity, oil furnaces and producer gas plants. The Gas Department for a long time past had very serious competition with electricity for power purposes, and the Electric Supply Committee have been authorised for many years past to charge much lower prices to manufacturers than to ordinary users of electricity, and that applied particularly to those taking h.t. current, where the price to-day was a little over a penny per unit, compared with the maximum rate for l.t. current of 6d. per unit. The justification for that had always been the necessity for obtaining a day load, and that was just as important from the point of view of the gas undertaking, as without it storage accommodation greatly in excess of the present storage would have to be provided.

Henley Wiring System.

The photograph illustrates a showcard, 15 in. by 10 in., which W. T. HENLEY'S TELEGRAPH WORKS Co. have produced to help electrical contractors to get business with the Henley Wiring System.

The showcard is produced in nine colours by the lithographic process and forms an attractive and neat advertisement,

THE NEW SHOWCARD.

The lettering "Electricity in your Home" is outlined in blue on the original card. In the reproduction the blue has, of course photographed white and has given the letters a "run-together" appearance. On the original they are, however, quite distinct The firm will be pleased to send contractors one or more of these cards on application.

Parliamentary Intelligence.

Telephone Development.

The House considered in Committee on Friday a resolution declaring it expedient to authorise the issue out of the Consolidated Fund of such sums, not exceeding in the whole fifteen million pounds, as were required for the further development of the telephone system and to authorise the Treasury to borrow money, by means of terminable annuities or by the issue of Exchequer Bonds, for the issue of such sums or the repayment thereof to the Consolidated Fund; and to provide for the payment of the terminable annuities or of the principal of and interest on any such Exchequer Bonds out of moneys provided by Parliament for Post Office services, or, if those moneys were insufficient, out of the Consolidated Fund.

Mr. KELLAWAY (Postmaster-General), who moved the resolution, said the sum of fifteen millions of capital expenditure proposed would, it was estimated, last till the end of April, 1924. Recalling the history of the telephone system, he pointed out that after the Government took it over they were almost exclusively occupied till the end of 1914 in putting it into proper condition, and could devote little time or money to extension. Then from 1914 to 1918 no development was possible. It was not until the beginning of 1919 that the engineering department was able to devote its attention to the development of the system. In 1919–20 £3 230 000 was proposed out of telephone capital for the development of trunk lines, exchanges, etc., of which amount £2 647 000 was actually spent. In 1920-21, out of a proposed expenditure of £6 884 000, £5 866 000 was spent, while last year out of £9 032 000, £7 438 000 was spent. For the present financial year the proposed capital expenditure amounted to £9 250 000, of which sum £2 760 000 was for the provision of new trunk lines and the completion of trunk lines now under construction. A sum of £5 740 000 was for new exchanges and the extension and improvement of existing exchanges, and £750 000 for sites and buildings.

Underground Trunk Lines.

The main object was that the whole of the trunk lines in this country should be no longer in the air, but underground, the advantage of which would be enormous. There was also included in this year's programme an amount of £504 000 for new underground cables. This included two long routes from Leeds to Edinburgh and from Worcester to Bristol. The former would complete the provision of the main routes for underground communication between London and the North of England and Scotland, while the latter would complete the underground communication between Birmingham, Bristol, and South Wales.

There was an item of £1 537 000 for the provision of new and the extension of existing switchboards.

There was still a very heavy programme of building work to be carried out in the near future, owing to the exhaustion of many exchanges and the approaching exhaustion of others. Estimates had been secured for a programme of work for the next five years which amounted to £35 700 000.

The number of new subscribers connected during the twelve months was 71 500, and the number of new instruments connected, including extensions of existing installations, was 134 000. The number of new subscribers for April was the second largest on record, and for May was the largest on record. Taking the country as a whole, the average time taken to get a reply from the telephone operator on a local service was six seconds from the moment when a subscriber removed the receiver from its rest. On the trunk underground cable the delay between Manchester and London had been decreased from twenty-one minutes to eight minutes. The Telephone Department was greatly indebted to the work of the Select Committee. He had not been able to adopt all of their recommendations, but he had adopted most of them.

After a short discussion, to which Mr. Kellaway replied, the resolution was agreed to, and reported to the House.

German Insulators for India.

In the House of Commons last week, Colonel Wedgwood asked the Under-Secretary of State for India whether any contract for insulators had recently been given out; if so, had the order been given to firms in this country; and, if not, when it was expected that the order would be placed?

In reply, EARL WINTERTON said the High Commissioner for India, who controlled purchases for, and under the orders of, the Government of India, had informed him that no contract had recently been made for the supply of insulators. He had, however tenders in hand for a supply of those articles, and the lowest acceptable offer (having regard to price, delivery and other relevant considerations) was that of a firm in this country for insulators of German manufacture. The contract was about to be placed accordingly.

To a question put on Monday by Mr. FINNEY, who inquired whether advertisements were appearing in German papers for tenders for porcelain and glass insulators,

Earl WINTERTON stated that the High Commissioner for India had informed him that he had not hitherto found it necessary to advertise directly in Continental papers.

Merchant Ships' Wireless Service.

Colonel Hurst asked the President of the Board of Trade last week whether he was aware that some 800 certificated wireless operators, mostly ex-service men, had been discharged by wireless companies since the institution of watchers on cargo ships; and whether, as the danger of failing to notice distress calls had been enhanced by the change, he would consider the desirability of abolishing wireless watchers in the Mercantile Marine and of re-employing certificated operators in their stead?

In reply, Sir W. MITCHELL-THOMSON said the main cause of the unemployment among wireless operators was the general depression in shipping which affected all classes of officers and men of the Mercantile Marine. Pending the results of the inquiry into the loss of the s.s. "Egypt," he was not in a position to say whether there was any failure in the wireless service on the occasion of her loss.

West Kent Electric Company.

Mr. GILBERT asked the Parliamentary Secretary to the Ministry of Transport (House of Commons, June 19) whether the representatives of the West Kent Electric Company, whose application for permission to erect a capital generating station at Erith was now before the Electricity Commissioners, had an interview with the Commissioners on the subject towards the end of last or the beginning of this year; if he would state whether the interview was an official or private one; if shorthand notes of the proceedings were taken; and if it was the custom of the Commissioners to grant such interviews to all applicants who had to appear before them at public inquiries?

Mr. NEAL: I understand that the Electricity Commissioners have had more than one interview with representatives of the company. These interviews were of a semi-official nature, and shorthand notes were not taken. It is the custom of the Commissioners to grant interviews if by so doing they can advance the public interest.

Wrexham Generating Station.

Mr. GILBERT asked the Parliamentary Secretary to the Ministry of Transport whether the Wrexham Corporation had applied for consent to extend their generating station; whether the Electricity Commissioners had refused to sanction such extension and had called upon the corporation to take what further power they required from the North Wales Power Company; whether the latter company had quoted a price of £6 a kW and 75d. a unit, which was the maximum price which they were allowed to charge; and whether, in view of the attitude taken up by the power company in the matter, the Commissioners proposed to reconsider their decision withholding consent to the extension of the Wrexham undertaking?

Mr. NEAL: The hon. Member has been misinformed. The consent asked for by the Wrexham Corporation was granted by the Electricity Commissioners. I understand, however, that the Corporation subsequently decided to obtain a bulk supply and are in negotiations with the company.

The Electricity Supply Bill.

We regret to notice that opposition to this Bill is still being organised, not only by a group of the power companies, but by some of the local authorities. We had hoped that the amendments made in the House of Lords would have placated the opponents of the measure, but, judging by the amendments to be moved in the committee stage in the House of Commons, this is far from being the case. Apparently the local authorities are going to move for the insertion of a proviso to Clause 15, with the object of precluding the powers and duties in connection with a municipal electricity undertaking, which is transferred under a scheme of reorganisation, being given to a company unless so determined by the majority of the local authority representatives upon the Joint Electricity Authority. This seems to be quite unnecessary as the matter is one to be dealt with in the respective schemes.

Telephone Subscribers (Deposits).

In reply to a question by Mr. Hurd, the POSTMASTER-GENERAL (Mr. Kellaway) stated in the House of Commons on Thursday last that the total amount held on deposit on March 31, 1922, was £1 441 000. The deposit usually represents two-thirds of the credit given for calls, and the present system of payment is more favourable to subscribers than the previous arrangement, under which all local calls were paid for in advance and trunk calls, against which a deposit was held, monthly in arrear. Deposits are required, not merely as security, but in order to finance the service during the period for which credit is given.

Rhondda Valley Telephone Facilities.

In reply to a question by Mr. Wm. John, the ASSISTANT POSTMASTER-GENERAL (Mr. Pike Pease) states that a scheme is being considered for a central telephone exchange to serve Treorchy, Treherbert and Pentre, provided a suitable site can be obtained.

Private Bills.

TORQUAY CORPORATION (ELECTRICITY) BILL passed its second reading in the House of Commons on Monday, and on Tuesday AYR BURGH (ELECTRICITY) BILL also passed its second reading.

As no petitions have been lodged against the Bill to authorise the LONDON ELECTRIC and CITY and SOUTH LONDON RAILWAY COMPANIES to raise additional capital, amounting to £3 500 000 for improvements and extensions, it will now proceed as an unopposed measure.

Electricity Supply.

Of Blackpool's electricity surplus of £14 322, £4 000 is being set aside for relief of rates, £6 000 is being placed to reserve, and £2 000 devoted to a working balance, £2 228 being carried forward.

A " Death's Head and Cross Bones " illuminated electric sign has been put into position in the PORT OF DUBLIN to indicate the spot where an electric cable runs from one side of the Liffey to the other.

Following the adverse balance of £924 on the account of WITNEY electricity undertaking for the year ended March 31 last, the Urban Council have decided to call in May and Hawes, consulting engineers, to inspect the works and accounts, and to advise the Council of any alteration they would suggest in connection with the management, prices, extension of output, etc.

Over 4 500 persons visited the HACKNEY ELECTRICAL DOMESTIC LABOUR AIDS EXHIBITION, the net cost of which was £470. The main object of the Exhibition, which took place at a period when trade was slack, was to introduce cooking, etc., by electricity into the homes of residents, and already definite arrangements have been made for the installation of 51 cookers. Many direct sales took place from Exhibition stands, including cooking appliances, vacuum cleaners, immersion heaters, fittings, and washing machines.

The inhabitants of NORTH HOUGHTON and CASTLETOWN are very anxious to have electricity supply, and they have, therefore, asked the Sunderland Rural Council to finance a scheme. Though the Sunderland Gas Company has undertaken the laying of gas mains the people are unanimous in their demand for electricity for lighting and domestic purposes, as it is considered cleaner, better and safer. The people are prepared to defray the cost by instalments. It was also mentioned that, for street lighting the cost would be £4 000, and for domestic supplies about £2 000, but an electrical engineer has been asked to prepare further particulars.

New Schemes and Mains Extensions.

SUNDERLAND Electricity Committee have authorised extensions of mains at a cost of about £1 200.

The Electricity Commissioners have given sanction to ST. ANNE'S Council to borrow £26 050 for electricity purposes.

KIRKBURTON Urban Council has consented to overhead cables being used in parts of the town by the Yorkshire Electric Power Co., and has decided to ask the company to submit a scheme for public lighting.

The North Wales Power Co. has offered to supply BANGOR Corporation with a bulk supply of electricity at £6 per k.W. of maximum demand with a minimum of £2 000 per annum plus ¾d. per unit.

In connection with the proposed purchase of the OSWESTRY Electric Light and Power Company by the Town Council, Mr. W. M. Selvey has been instructed to make a valuation of the undertaking for the Council.

CALNE Town Council has instructed the Gas Committee to consider the question of establishing electricity works in connection with the gas undertaking, and the advisability of applying for a Provisional Order for electric lighting.

BLACKPOOL Electricity Department have made a start with their scheme of extensions, which are estimated to cost £169 000. The Tramways Committee have received tenders for the construction of a new switch-room annexe for e.h.t. switchgear.

It has been decided that from the date of the termination of its agreement with the Bury Corporation at the end of the present calendar year, the RADCLIFFE Council shall obtain its bulk supply of electricity from the Lancashire Electric Power Company.

SUNDERLAND Electricity Committee has been canvassing certain districts of the town for new consumers with the result that considerable extensions of mains have been authorised to meet the demand, the total cost being estimated at £5 954, which is to be borne out of capital account.

PORTSMOUTH Town Council have approved of the Finance Committee making a loan of £91 000 from the corporation sinking funds at £4 10s. per cent. per annum (free of income tax), to the Electric Light Committee, repayable by instalments of principal and interest within a period of eleven years from March 31 last.

The NORTHWOOD ELECTRIC LIGHT AND POWER Co. are extending their distributing mains to Ducks Hill Road, Jacketts Lane and Copse Wood in the Northwood district, Sharps Lane, Manor Road, Church Avenue, King Edward Road and High Street in Ruislip and Elm Avenue and Lime Grove in the Eastcote district.

BANGOR Corporation recently applied to the Electricity Commissioners for sanction to a loan of £4 000 for supply mains, services, etc. Permission has now been received to borrow £3 768, £232 being deducted as representing the amount which would have been repaid had the loans been sanctioned at the time of expenditure.

WHITEHAVEN Town Council have received sanction to borrow £3 500 for services, and £2 800 for extension of the mains to the Council houses, at Bransty. They have also decided to oppose the application by the Cumberland Waste Heat Owners' Co. for a Special Order to empower the company to supply electricity in the urban districts of Egremont and Cleator Moor.

Last week the Tynwald Court heard the petition of DOUGLAS (ISLE OF MAN) Town Council for sanction to borrow £62 000 for carrying out the work authorised by the Douglas Corporation Electric Light and Power Act, 1921. The petition was strongly opposed by the Attorney General, on the ground that Douglas had now got a debt of £636 000, which was too heavy for a town of its size.

Alteration of Charges.

A revised scale of charges has been adopted by WEST BROMWICH electricity department.

BRIERFIELD Urban Council have fixed a flat rate of 7d. per unit, net, for electricity used by cinemas.

NELSON Electricity Committee have decided to reduce their charges for lighting by ½d. and for power ¼d. per unit.

MAIDENHEAD Town Council has reduced the charge for electricity for lighting from 10d. to 9d. per unit as from June 30.

CARLISLE Electricity Committee has reduced the ordinary charges for electricity from 80 to 60 per cent. above pre-war rates.

The increase of 100 per cent. in electricity charges which was made some time ago by SHREWSBURY Town Council is to be reduced to 75 per cent. as from this month's readings.

ROTHERHAM Town Council has fixed, as from July 1, a minimum charge of 10s. for electricity for any quantity consumed in any one quarter up to 20 units.

TONBRIDGE Urban Council has decided to reduce the charge for electricity for private lighting by 2d. per unit as from October 1, and for street lighting by 50 per cent.

The charges for electricity for lighting at LOWESTOFT are to be reduced as from July 1, by ½d. per unit, and the discount for both power and lighting increased to 5 per cent.

CREWE Town Council has reduced the price of electricity by 12 per cent., and has applied to the Electricity Commissioners for permission to erect an overhead cable to Sydney.

PORTSMOUTH Town Council has reduced the price of electricity for lighting to 7d. per unit for the first 5 000 units per annum, 6¼d. from 5 000 to 7 500, 6d. from 7 500 to 10 000, 5¼d. from 10 000 to 20 000, and 4⅜d. beyond.

RUSHDEN and District Electric Supply Co. have reduced the charge for electricity for power by ½d. per unit. For lighting, a scale has been introduced for the benefit of large users at 10d. per unit for the first 200 units per quarter and 8d. beyond.

NORTHAMPTON Electric Light and Power Co. has reduced the charge for electricity for power by another ½d. per unit, and that for lighting by 1d. per unit, with additional reductions to large users by the introduction of the following scale :—8d. per unit for the first 200 units per quarter and 6d. beyond. The rates for hired motors have been further reduced by 10 per cent.

The new electricity charges at ST. ANNES for this quarter are as follows : Lighting : 7d. per unit net, or maximum demand rate 8d. and 5d., cinemas and signs, 4½d. ; motors, heating and cooking, up to 500 units per quarter, 2d. net ; over 500 and under 5 000 units, 1¾d. per unit, less 10 per cent. ; over 5 000 and under 10 000 units, 1½d., less 15 per cent. ; over 10 000 units, 1¾d. per unit, less 25 per cent. The charge for current for street lighting is 3½d.

From this month's meter readings the flat rate of charging at MANCHESTER will be reduced from 7½d. to 7d. a unit, and on the sliding tariff the fixed charge remains as at present, but the units consumed will be at 2½d. instead of 3d. The ordinary power rates have been reduced by about ½d. a unit, and now vary from 3·25d. to 1·4d. Special consumers, with a coal clause in their agreements, will benefit from the reductions in coal, in addition to 15 per cent. reduction in the war percentage additions. The question of allowing discounts has been postponed for the present.

The WESTMINSTER Electric Supply Corporation announce that from the midsummer quarter's readings a reduction of ½d. per unit will be made on all units in excess of 1 000 used in any one calendar year for lighting purposes. From the date of the midsummer quarter's readings, therefore, the charges will be as follows :— Lighting : For the first 1 000 units used in any one year, 7½d. per unit ; for the next 3 000, 6½d. ; for all units used in excess of 4 000, 5d. Heating, cooking and motors : If taken through a separate meter, 1½d. per unit. The above rates are subject to a minimum charge of 10s. per quarter.

Chagford and Devon Electric Light Company have notified CHAGFORD consumers of their intention to increase the lighting charges after the June quarter by 2d. per unit. A protest against the increase, which brings the charges up to 1s. per unit, is being made and the Parish Council, whose contract with the company terminates in November, have asked the company whether they propose making a corresponding increase in the charge for street lighting. The Council are considering approaching the Ministry of Transport with a view to ascertaining whether, under the local circumstances, such an increase would be justified.

D

Municipal Accounts.

The PLYMOUTH electric trams are paying and doing well according to the engineer's return for the financial year ended March 31st. The income amounted to £169 994, and from the motor 'buses £30 061. The expenditure left a gross surplus of £32 399 on the former, and £3 884 on the latter. After payment of capital charges there remained a net profit of £11 863 on the trams, and a loss of £1 542 on the 'buses, leaving a balance of £10 321, which it has been decided to place to the reserve fund. During the four weeks ended June 3 the passengers carried on the trams numbered 2 182 070, and the receipts were £14 827, compared with 1 746 076 passengers and £11 742 receipts in the corresponding period of last year.

The total income of LOWESTOFT ELECTRICITY DEPARTMENT for the past year amounted to £42 268 compared with £39 803 in the previous year. Working expenses were £30 932, a decrease of £6 652. The gross profit amounted to £11 335 compared with £2 219. After providing for interest and sinking fund charges (£10 942) there remained a credit balance of £393, compared with a loss last year (if sinking fund charges had been met) of £7 314. The income for the TRAMS for the year (£22 115) showed a decrease of £2 180 but working expenses also decreased by £3 652. After allowing for interest and sinking fund charges (£5 533) there was a deficiency of £2 158, a decreased deficiency of £808 as compared with last year.

For the year ended March 31 there was a surplus of £44 564 on the MANCHESTER electricity department. Interest and sinking fund charges on the new generating station at Barton and the high tension mains therefrom were met out of revenue. The total income was £1 429 995, and the expenses (exclusive of depreciation) £977 102. The decrease in business during the year, due to trade depression, was 21 per cent., the annual sales totalling 158½ million units, compared with over 199½ the previous year. The average price paid for fuel fell 1s. 4d. a ton, and the fuel consumed rose 0·03 lb. per unit sold. The efficiency of the distributing system equalled 84·77 per cent., the quantity absorbed in the mains and distributing stations being 15·23 per cent., an increase of 3·44 per cent. on the previous year. The increase was mainly due to the reduced sales during the year on the large consumers' accounts. Good progress has been made with the lighting of the various housing estates, and work has been completed on the inhabited portions at Anson, Blackley, Catterick Hall, Clayton, Gorton Mount and Wilbraham Road. The electric lighting of several streets has been carried out, thus completing the scheme of electric lighting so far sanctioned for the main thoroughfares.

During the past year OLDHAM electricity undertaking has made a profit of £1 403, compared with £3 836 in the previous year. At a meeting of the Electricity Committee last week, the chairman (Alderman Hardman) said that they had an adverse balance of £1 900 to overcome on the first two quarters, and had been afraid they might be obliged to increase the rates. He thought they would all regard the outcome as very satisfactory, particularly as they had had to pay so much for coal. The increase in units sold over the previous year had been approximately 4 millions. He expected that during next year they would have an increase of 22 millions. He thought that at an early date they would have to consider what to do with the prospective profit. They had been getting some prices from other towns, and at a future meeting the committee would be asked to consider a scale of reduction in prices for electricity. In wages, they had had an increase of £2 000 to meet, and in materials for distribution another £2 000. This all had to come out of the revenue. The interest on sinking fund and loan came to £39 000, as against £24 000 the previous year, again showing a considerable increase in the costs against the undertaking. The revenue was about £20 000 more than in the previous year. The total number of units sold was 862 546, as compared with 435 068. The number of cwts. of coal used was 24 268, against 23 005, and the amount of coal used per unit generated 2·50 lb. against 4·45. The efficiency was put at 79·38 per cent., as compared with 75·18 per cent.

The annual report of BURTON electricity undertaking shows that a gross profit was made of £36 235. After meeting the loan charges and other items, the surplus remaining was £19 812, compared with £12 611 last year. Of this surplus, £14 812 has been allocated to the renewals fund, and £5 000 to rate fund. The amount of the renewals fund at March 31, 1921, was £3 346; the income during the year (amount transferred from revenue account £14 812, and contributions under agreement, etc., £425) £15,237; making a total of £18 583; which, less excess capital expenditure of £13 570, left a balance remaining at March 31, 1922, of £5,013. The total capital expenditure, including £69 373 during the year, is £274 552, of which £54 189 has been provided out of revenue. The net outstanding debt at March 31 was £153 002. The total number of units sold was 8 157 743, compared with 7 132 945 last year, an increase of 1 025 698 units. The power supply shows an increase of 866 159 units on last year. The H.P. in motors connected has increased by 964 during the year, the total now being 9 195. The total costs have decreased from 1·588d. per unit to 1·434d., or 9·7 per cent. The total maximum load of 3 490 kW was reached on December 16, 1921, and represents an increase of 790 kW. It is interesting to note that the gross income of the undertaking on December 31, 1894, the first year of the works' existence, was £529, the working expenses £844, and a gross loss of £315 was made.

Electric Traction.

WEST BROMWICH Corporation have applied to the Ministry of Health for sanction to a loan of £75 000 for the reconstruction of the tramway track.

WOLVERHAMPTON Corporation have decided to commence work on the general renewal of the tramway track, and a tender (at £3 871) has just been accepted for renewing the Waterloo Road route.

The first section of the new electric tram service on the Leberton-Granton route in EDINBURGH was officially inaugurated on Tuesday by Lord Provost Hutchison by the breaking of a broad ribbon stretched across the street at the old border line which formerly separated Edinburgh from Leith.

SUNDERLAND Town Council has approved a scheme submitted by the Tramways Committee for the establishment of a retirement fund for members of the traffic staff. Subject to a certificate of exemption under the Unemployment Insurance Act, 1920, being granted by the Ministry of Labour, a fund will be established by which the Corporation and the employees will each contribute 10d. per man per week. The retirement allowance will be reckoned at 50 per cent. of the wage for the time being in operation for motormen. The Corporation is not to be liable to contribute in any one year more than 20 per cent. above their present contribution under the Unemployment Insurance Act, 1920, in respect of tramway employees. The Corporation unanimously approved the scheme in principle, and the final drafting of the scheme will be proceeded with, subject to official sanction.

The scheme for the construction of an EAST-TO-WEST railway in NORTH LONDON has been revived in a modified form. The projected line would connect the Great Northern, Great Eastern, Great Central and Great Western Railways. Probably the line, if constructed, will be equipped electrically. It would be twenty miles in length, connecting the joint railway of the G.W. and G.C. Companies near Denham, with the G.N. main line, near Wood Green, and the G.E. line at the adjoining Palace Gates terminus, skirting *en route* many towns and villages, including Watford, Elstree and Chipping Barnet. No doubt such a line would be extremely useful, and would increase the transport facilities in North London. It would also enable trains to proceed from the north to the south of England without coming into London. Direct rail communication between the northern and north-western suburbs would be given, and it would enable the Eastern Group of railways to run circular suburban passenger services from and to their respective termini.

Personal and Appointments.

Professor A. S. BUTLER, M.A., has resigned the chair of Natural Philosophy at St. Andrew's University.

Keighley Tramways Committee recommend the Council to appoint CAPTAIN C. JACKSON of Sheffield to the post of tramways manager.

MR. W. H. DURRELL, assistant electrical engineer, Eastern Bengal Railway, has been appointed to officiate as electrical engineer of the railway.

MR. A. G. WARREN is appointed to officiate as electrical inspector to the Indian Government in the United Provinces, *vice* Major H. C. C. TUFNELL, resigned.

Barnes (Surrey) Urban Council have fixed the salary of the electrical engineer, Mr. C. S. DAVIDSON, at £1 000 per annum, to include bonus, as from June 1. His previous salary was £952.

Wimbledon Town Council has made a grant of £75 to MR. W. J. OSWALD, chief assistant electrical engineer, for the services rendered by him as acting chief electrical engineer from February 1 to May 31.

MR. F. J. FOXLEE, district electrical superintendent of the Bengal-Nagpur Railway, is on six months' leave and Mr. D. KERRIDGE, district electrical superintendent, Khargpur, is officiating in his place.

Southport Town Council has appointed Mr. W. T. GANN principal assistant to the electrical engineer (Mr. E. Moxon) at a commencing salary and bonus of £469 a year, to be increased by two annual increments to £580.

Mr. A. J. BRIDGE informs us that he has left the service of Metropolitan Vickers Electrical Company, Manchester, to take up the appointment of manager of the Publicity Department of The Brush Electrical Engineering Company, Loughborough.

Owing to ill-health Mr. W. R. RENDELL has decided to resign the general managership of the Metropolitan Electric Supply Co. in the autumn. He has held the position with great success since the commencement of 1916, and his resignation has been accepted with regret by the Board.

In connection with the forthcoming retirement of Mr. J. DYER LEWIS, H.M. Divisional Inspector of Mines in charge of the South Wales Division, Mr. J. M. CAREY, at present serving as a senior inspector in that Division, has been promoted to take Mr. Dyer's place, and Colonel J. A. S. Ritson has been appointed a senior inspector in place of Mr. Carey.

Business Items, etc.

The address of the hon. secretary of the Sheffield and District Wireless Society (Mr. L. H. Crowther) is now 18, Linden Avenue, Woodseats, Sheffield.

The COMMERCIAL-CABLE COMPANY announces the removal of its administrative and central operating offices to the Mackay House, 27–33, Wormwood-street, E.C.2.

Mr. I. STEPHENSON, junr., announces that he is continuing the business of his father, the late Mr. I. Stephenson, electrical engineer, of 36 and 37, Flowergate, Whitby.

The address of the MINES Department is now Dean Stanley Street Millbank, Westminster, S.W.1. Telephone No.: Victoria 9310 Telegrams: Minindust, Vic., London.

Owing to the engineering and shipbuilding disputes, the departure of the s.s. BRITISH TRADE has been somewhat delayed, but we are informed that the ship will sail at an early date.

Mr. J. E. Sayers announces that he has taken into partnership Mr. Thomas G. Crum, who has been his assistant for several years. The business will now be carried on under the firm name of JAMES E. SAYERS AND CO., consulting engineers and electricians, Ocean Buildings, 190, West George Street, Glasgow.

KENNEDY AND DONKIN have removed to new offices at Broadway Court, 8, Broadway, Westminster, London, S.W.1. The new offices are situated on the fourth floor of the building, which is midway between St. James's Park Station and Victoria St eet. The telegraphic address, " Kinematic, Vic., London," will remain unaltered, but the telephone number will be Victoria 3601 (3 lines).

In these days accurate and up-to-date information is essential, especially for engineering firms. Though the technical journals supply, or endeavour to supply the needful, there are so many of these to be perused if one is to make sure that nothing important is missed. Time and opportunity are often lacking for this laborious task, and consequently any system which eliminates some of the work should be welcome. The LEFAX SYSTEM claims to have solved the problem, for they publish selected articles, boiled down to essentials, in a standard loose-leaf form, self-indexed and classified for filing in filing boxes or cabinets. The sheets are also punched for insertion in the pocket firm. Standard engineering tables and data, as well as blank forms, are also supplied. The British agents for the system are Norman and Hill, 54, Holborn Viaduct, London, E.C.1, who will supply further particulars.

Obituary.

By the death of FREDERICK WM. SANDERSON, headmaster of Oundle School, science loses an ardent disciple and education a man of original mind. Mr. Sanderson was the author of several elementary text-books on electricity, mechanics and geometry.

We regret to announce the death of Mr. F. R. REEVES, who was for many years secretary, and later secretary and general manager of Crompton and Co., Ltd. Subsequently he became managing director of the Sevenoaks and District Electricity Co., and he was also a director of the Calcutta Electric Supply Corporation and two or three British provincial supply companies. Mr. Reeve was 79 years of age.

The death is announced from New York of Mr. GEORGE GRAY WARD, vice-president of the Commercial Cable Co., in his 78th year. Mr. Ward, who was born in Hertfordshire and educated privately at Cambridge, entered the Electric Telegraph Co. In 1865 he joined the Egyptian Government Telegraph Service and was stationed for about three years at Alexandria, and in 1869 he accepted a position with the first French Atlantic Cable Co. Returning to England in 1874, he joined the Direct United States Cable Co. as superintendent, but in 1884 he accepted the post of commercial secretary and general manager of the Commercial Cable Co. In 1890 he was relieved of the position of secretary and elected vice-president of the company, and in 1902 he was made chairman of the Board.

Mr. Ward displayed great activity in organising the Commercial Cable Company's system and in laying its cables; upon the extension to Japan being completed in 1906, he was decorated by the Emperor with the Order of the Commander of the Rising Sun. Mr. Ward was instrumental in laying the New York-Hayti cable in 1896 and had much to do with connecting Portugal directly with America, via the Azores. He also rendered valuable assistance to the Deutsche Atlantische Telegraphen Gesellschaft in establishing the direct communication which formerly existed between Germany and the United States, and upon the completion of the Emden-New York cable in 1900 the ex-Kaiser conferred on him the Royal Order of the Royal Prussian Crown of the Second Class. Mr. Ward was vice-president and general manager of the Commercial Pacific Cable Co., a vice-president of the Postal Telegraph Co., vice-president of the Mackay Companies, and a director of several other companies. He was also a member of the New York Chamber of Commerce and of the American Institute of Electrical Engineers, and local hon. secretary and treasurer of the Institution of Electrical Engineers.

Institution Notes.

The annual conversazione of the INSTITUTION OF CIVIL ENGINEERS will take place at 8.20 p.m. on Tuesday next at the Institution offices.

The following officers have been elected for the 1922–23 session of the RÖNTGEN SOCIETY:—*President*, Sir Humphrey Rolleston; *Vice-Presidents*, Professor Sir William H. Bragg, Professor Sir Ernest Rutnerford, A. E. Barclay; *Hon. Treasurer*, Geoffrey Pearce; *Hon. Secretaries*, E. A. Owen, Russell J. Reynolds.

The BRITISH ENGINEERING STANDARDS ASSOCIATION have issued their revised specification (No. 7, 1922) of insulated annealed copper conductors for electric power and light. It contains the information as to sizes, tests, standard thicknesses of dielectric, etc., given in the 1919 edition, with the addition of a new size of cable 0.03 sq. in. in area. Standard thicknesses for cab tyre sheathing have also been incorporated. The Association have also issued Specification No. 152, which is a metric edition of No. 7. One additional size of cable of 1.5 sq. mm. area has, however, been included as this is a size commonly used in countries using the metric system. Copies of the specifications may be obtained from the Association, 28, Victoria Street, London, S.W.1, price 1s. 2d. each.

Miscellaneous.

The BRITISH INDUSTRIES Fair will be held as usual next year, from February 19 to March 2, but the Birmingham section will have a more comprehensive display of mechanical plant.

Mr. Herbert W. Sullivan is seeking leave TO AMEND DRAWINGS forming part of the specification of LETTERS PATENT No. 166 970, for " Improvements in or relating to duplex and like telegraphic systems."

The CONFERENCE which had been arranged to take place on Wednesday, between all the ENGINEERING UNIONS and the Engineering Employers' Federation, to discuss the employers' demand for a reduction of the war bonus, has been postponed.

The staffs of the EASTERN AND ASSOCIATED TELEGRAPH COMPANIES have sent a cheque for £1 000 to St. Bartholomew's Hospital for maintaining a bed in memory of the late Lady Denison-Pender, wife of the chairman of the companies, Sir John Denison-Pender.

It is announced that the BOILERMAKERS AND IRON AND STEEL SHIPBUILDERS' SOCIETY have agreed to accept the terms agreed upon between the Engineering and the National Employers' Federation and the other trade unions concerned on the 2nd inst. The dispute is, therefore, now terminated.

The current number of the " DECIMAL EDUCATOR " includes reports of the meeting of the National Chamber of Trade, which passed a unanimous resolution advocating the adoption of the high-value penny; American views of the " Easy Stage " proposal (a modification of which is fully set out), and of the progress of the U.S.A. metric bill.

An inquiry was opened on Tuesday by the Board of Trade Committee into the complaint of DUMPING VULCANISED FIBRE in this country. After taking some evidence, the Committee decided to adjourn the inquiry indefinitely. A difficulty was experienced in dealing with the case owing to fluctuations in the market price since the complaint was lodged.

Last week's issue of the " Manchester Guardian Commercial " was the third of the series of special numbers on RECONSTRUCTION IN EUROPE. Mr. J. M. Keynes, the general editor of the series, has assembled a most valuable collection of articles on the Genoa Conference, on the problem of Austria, together with an exhaustive survey of the present position and prospects of the textile industries of Europe. Among the contributors are Mr. Keynes, Signor Nitti, Baron d'Estournelles de Constante, and Prof. Cassel.

At a meeting in connection with the " SAFETY FIRST " movement, held at the Institution of Mechanical Engineers last week, Mr. A. Stevenson Taylor, Home Office Senior Engineering Inspector, stated that in 1920 nearly £6 000 000 was paid in compensation for industrial accidents, and he was convinced that by proper teaching of workers and employers a great number of those accidents were preventible. In the same period 1 400 fatal accidents were reported under the Workmen's Compensation Acts and 140 000 accidents of all classes occurred.

Education Notes.

The foundation stone of the new EAST MIDLAND UNIVERSITY at Nottingham was laid last week by Viscount Haldane, who announced that an anonymous donor had sent him a cheque for £100 000 towards the endowment of the University. An appeal for support was made to large manufacturers and employers of labour, as true scientific knowledge could never be an enemy.

The University Court of ABERDEEN UNIVERSITY have asked the Committee on Engineering to confer with the governors of Robert Gordon's Technical College on the question of the creation of a school of higher education in engineering, including the foundation of a Chair of Engineering in the University. Professor C. Niven has resigned the Chair of Natural Philosophy as from October 1 next.

Imperial Notes.

PORT ELIZABETH (S. Africa) Municipal Council have recently placed contracts with British firms for additional generating plant of the value of about £52,000.

LITHGOW (N.S.W.) Council have placed an order with Ramsay, Sharp and Co. for electricity generating plant for supplying electricity in the centre of the town. Orders for mains and a h.t. transmission line to the Oakley Park Colliery are still to be given out.

Mr. Butters, manager of the Government hydro-electric department, has made proposals for supplying electrical energy in bulk to ZECHAN (Tasmania) Municipality, and the payment of £1 184 per annum for ten years to cover interest and sinking fund on the Council's present electrical plant.

According to the "Industrial Australian and Mining Standard," the Electric Supply Co. of Victoria has offered to arrange for the distribution in Ballarat and adjacent districts of the electrical energy supplied from the Morwell coalfields, provided the municipalities undertake to meet financial obligations required for converting plant and mains, and also if an extension of its present lease be granted, or that the undertaking be purchased by the municipalities at the expiration of the existing lease. Further negotiations are pending between the councils, the Electricity Commissioners and the company. The company has asked £500 000 as the price at which it would be willing to part with the present plant.

The NEWCASTLE (N.S.W.) City Council and Chamber of Commerce have again been urging the Government to grant facilities for the electrification of the district tramways. In reply to a recent deputation, the Chief Commissioner of Railways (Mr. Fraser) said the Commissioners had repeatedly endeavoured to get money for the electrification of the Newcastle tramways, but their application had been refused each time. They needed £1 100 000 for the work, and it was no use starting unless they felt sure that there would be sufficient money to continue the work. It was no use tinkering, as had been done in Sydney with the proposed electrification of the railways. The provision of electric railways in Sydney was urgent, and if funds were found for that the Government might consider it equally fair to provide funds for Newcastle.

SYDNEY (N.S.W.) Electricity Committee have decided to postpone the question of erecting a new power station and to enter into negotiations with the Railway Commissioners for the supply of electricity in bulk. The Council would want a supply as cheaply as they can generate it themselves, and the agreement would be terminable by either side on five years' notice. A new power house would cost the Council from £1 000 000 to £1 250 000, and it would have to be ready in five years time, but the Commissioners can give a supply whenever it is required. There is a good deal of opposition to the proposed agreement, some members maintaining that the Council could generate current as cheaply as the Commissioners. Already nearly £5 000 000 capital has been expended on the undertaking, and the Council is, it is claimed, as well able to find the money for extensions as the Commissioners.

Foreign Notes.

A PROVISIONAL TELEGRAPHIC CONVENTION has been made between FINLAND and RUSSIA, was signed on the 13th inst., and came into force this week. Telegraphic connection between Finland and Russia has, therefore, been resumed over the Helsingfors-Moscow and Viborg-Petrograd lines, and the Finnish Government will not oppose the establishment of telegraphic communication between Northern Norway and Northern Russia over Finnish territory.

The use of ELECTRICITY for FARM WORK is steadily expanding in the United States. Apart from the extension of transmission lines from urban centres, there is an increasing demand for independent generating plants. These latter are usually petrol-driven sets, though there are also a number of small water-power stations. It is estimated that there are already over 300 000 of these independent plants in use, and the number is rapidly increasing. Electricity is employed for lighting the farm house and adjacent buildings, and for a great variety of power purposes. Owing to its convenience and efficiency, electricity is rapidly displacing rival forms of power.

The order for the 80 freight locomotives required by the PARIS-ORLEANS RAILWAY, to which we referred in our issue of June 9, (p. 698), has been placed with the Société Oerlikon and the Société de Construction des Batignolles, both in Paris. These locomotives are each for a one hour rating of 1 720 H.P. The Société Oerlikon is to supply and erect the electrical equipment, while the Société de Construction des Batignolles deals with the mechanical part. Except in the case of the five first locomotives, which will be completed at the works of the Ateliers de Construction Oerlikon and will serve as models, the whole electrical equipment will be built in France, to the Oerlikon design, at the works of the Société Oerlikon. The locomotives are intended for goods trains and are to be capable of hauling a load up to 1 200 tons; but they are also to be suitable for passenger service, in which case a speed of about 68 miles per hour must be attainable. The locomotives are equipped with four motors wound for 1 500 V d.c. and having each an output of 430 H.P. measured at wheel rim.

Wireless and Telegraph Notes.

The West India Committee announce that a system of wireless telephony has been successfully established in the TURKS AND CAICOS ISLES (B.W.I.), Grand Trunk now being connected with the South Caicos and Salt Cay, distances of twelve and eight miles respectively.

A senseless and stupid outrage was perpetrated on Sunday at the VALENCIA (co. Kerry) cable station of the Western Union Telegraph Company. During the night some masked and armed men forcibly entered the station and smashed several instruments, doing damage to the extent of £3 000.

A further meeting in connection with WIRELESS BROADCASTING was held last Friday at the General Post Office. The Postmaster-General was present, and representatives of the twenty-three firms who attended the conference held a month ago. The proceedings were private, and the manufacturers are holding a further conference among themselves this week.

An agreement was recently made between the Italian Government and the Eastern Telegraph Company for the re-opening of the submarine CABLE BETWEEN TRIESTE AND CORFU. The new company have agreed to give special facilities for the transmission between Italy and Egypt of State and Press telegrams, as well as between Italy and Eritrea, Abyssinia and Italian Somaliland.

Catalogues, Price Lists, &c.

RONALD TRIST AND CO., specialists in sand-blast machinery, have published in pamphlet form, a reprint of a paper on "Sand-Blasting," by Mr. E. L. Samson, read before the Institution of British Foundrymen (London Branch) last February. The paper is fully illustrated and gives much useful information.

"Tips on Odd Jobs about the House" is the latest publication of the RAWLPLUG CO., and without doubt will prove most popular. The booklet is attractively produced with dainty little marginal illustrations in blue, showing various household fixtures and the Rawlplug tools required to repair minor defects, or to put up the fixtures.

The importance to business men of the DICTOGRAPH TELEPHONE SYSTEM is clearly shown in an illustrated booklet just published by Dictograph Telephones, Ltd. One of the great advantages of this system is that there is neither mouthpiece nor earpiece to hold, and conversations can be carried on easily and clearly if the speaker is as much as 15 ft. away from the instrument.

ISENTHAL AND CO. have just published a new pamphlet (Section 2) dealing with their regulating resistances. The new publication gives illustrations and particulars of the company's field regulators for back of board (B.O.B.) mounting, dimmers for incandescent lighting, resistance units, load and standby resistances, meter calibration resistances, arc regulators, etc.

SIMPLEX CONDUITS, LTD., have just issued a new illustrated price list (No. 909) comprising Section T. of their manufactures (light and heavy gauge conduits, couplers, normal and sharp bends, circular junction boxes, ceiling rose and pendant fittings, porcelain connectors, screwing tools, etc.). The firm's original intention was to publish this catalogue on January 1, but owing to the extreme instability of prices at that time, its issue was postponed until June 1. Even now the prices of conduit have been omitted from the list and printed on a separate card, in order that they may be revised when necessary and that the section may not be obsolete within a few weeks of its appearance.

We have received from the GENERAL ELECTRIC COMPANY a copy of a new edition of their electric light supplies catalogue, in which all prices have been revised to present day level. Numerous illustrated descriptions with dimensions, weights and prices are given of distribution boards, cutout boards, branch switches, "H. and H." snap switches, wall plugs, ceiling roses, lampholders, flashers, etc. A handy catalogue of ELECTRICAL MEASURING INSTRUMENTS has also been issued by this Company. It is an abridged edition of section M of their complete catalogue, and covers switchboard ammeters and voltmeters of both round and sector patterns, pedestal type, instruments and portable instruments, "Salford" testing sets, meggers, etc., the prices of which have been revised to date.

The business of VERDUN CUTTS & CO., electro-metallurgists, of Fargate, Sheffield, has been converted into a private limited liability company. The business was started about twelve years ago by Verdun O. Cutts and during that time the firm have designed and erected many complete electro-metallurgical works and plant. They have carried out work for clients in Great Britain, the Colonies, India, on the Continent and in China and Japan, and they have also done a good deal of original work in the design and operation of plant for the production of steel, non-ferrous metals and alloys, ferro-alloys, precious and rare earth metals, artificial abrasives, etc.

Companies' Meetings, Reports, etc.

British Electric Traction.

The twenty-sixth ordinary general meeting of the British Electric Traction Co., Ltd., was held on Friday at the Holborn Restaurant, London, Mr. J. S. Austen (the Chairman) presiding.

The chairman in moving the adoption of the report and accounts, said :—We propose to ask you to-day to sanction the payment of a dividend of 4½ per cent., which compares with 4 per cent. paid last year. There may be some among you who will ask why we are to-day paying an increased dividend when our earnings are only about the same as they were last year. Our answer to that is that we believe that our income is more stabilised and is becoming still more stabilised, and that consequently we are justified in going rather nearer to our limit than we have done before. With your permission I will explain as simply as possible exactly what we have done during the past year. We have earned this 4½ per cent. which we propose should be paid, and in addition we have earned a sum of about £31 500. That sum of £31 500 we propose to dispose of by putting £14 000 to reserve and by adding to our carry forward a sum of about £17 000. The net results are almost exactly the same as those of last year, but, although there has been very little change in the result among the component parts which make up the whole, there have been some very material changes. It is not necessary to specify them, but I may say that we have had increases on some investments aggregating about £41 500, but against that we have had losses on others amounting to £40,000. These sums, as you see, are very considerable, but it is only to be expected that in a company like this, with a multitude of different investments, the gains as a rule will meet the losses, and in good years surpass them.

Current Year's Prospects.

It is difficult to draw any general conclusion from these results, but perhaps it may interest you if I summarise what the various branches of our business are doing at the moment. Our main business may be divided into three classes—namely, tramways, electric power and electric lighting. With regard to the tramways, during the current year up to date there is a falling-off in receipts. It may not be quite safe even to try to specify what that falling-off is, but perhaps it will give you a general idea, if I say 20 per cent., which naturally is a serious amount ; but against that the tramways can set a very considerable saving in expenses. On the whole, I should doubt if the general results from tramway working during the present year will be so good as they have been in the past. Then we come to electric power, and there it is obvious that owing to the engineering strike, depression in trade, and so on, there will be a decrease. With regard to electric lighting, however, which includes the use of electricity for domestic purposes, that received a stimulus during the war, and up to the present there has been no setback, and I do not think that any setback is coming. There is a fourth portion of our business and that is the omnibus business.

Subsidiaries' New Issues.

During the year two of our subsidiary companies have made new issues of capital ; one is the Shropshire Power Co., which made a very successful issue, and the other is the British Automobile Traction Co., which was not so favourably received by the public. Those of you who have taken the trouble to examine our list of investments will have found that we have during the year increased that list by a number of investments of what I may call a general nature. Since the close of the year we have still further increased those investments, and I think it is probable that by the time you get the next report we shall have very considerably increased that list. In that connection I may say that it will probably be advisable to alter the form in which we at present show our investments, which is not altogether satisfactory.

It is the present intention of the directors, if circumstances are satisfactory, to declare an interim dividend upon the stock about December next.

With regard to the immediate prospects, it is really very difficult in a company like this, with such a variety of undertakings, to forecast exactly what one is going to do. I prefer to touch on the dividend question. I have now had two years' experience of this company, and I am pleased to say that with that experience my regard for the company has increased. It has been the business of my life, mainly, to build up trust companies, and in every case the result has been satisfactory, and I can see no reason why we should not have steady progress in this company.

Mr. Emile Garcke (deputy-chairman), seconded the resolution, which after a brief discussion, was carried unanimously.

Madras Electric Supply Corporation.

At the annual meeting of this company, last week, the chairman, Mr. James Gray, stated that, owing to the delay in installing additional converting plant, the number of new consumers was not as high as usual, but the total connections and the gross revenue were more than maintained in consequence of several large power consumers having come on to the company's mains. With the exception of the tramways, which were affected by the strike in the early part of 1921, increased supplies of current were provided all round. The gross revenue increased by £11 091, but the working expenses showed an increase of £12 297, due to the higher cost of fuel and to a readjustment of salaries between the company and the tramway company. The adjustment of exchange showed a debit of £19 739 instead of a credit of £1 254, so that there was a total reduction of £22 199 compared with 1920. Their application to the Government of Madras a few years ago to increase the rate for current for lighting and fans on a combined circuit from 4 annas to 5 annas was absolutely necessary. They were indebted to the Government for removing the restriction of three years from August 1, 1919, during which the increase was to operate, and the position now was that any revision of the tariff would be subject to the ordinary provisions of the Indian Electricity Act, under which all Indian electric supply companies operated.

After payment of the preference dividend there was a balance of £30 356, which would be applied in paying a dividend on the ordinary shares of 8 per cent. (tax free), paying additional remuneration to the directors, and after placing £5 000 to reserve, a sum of £9 728 would be carried forward. The expenditure on buildings and machinery amounted to £29 071, representing chiefly a new water tube boiler and three new sub-stations. Expenditure on mains (£21 217) included new high tension feeder lines in various parts of the area. The debenture stock sinking fund reserve and general reserve fund showed substantial increases and now more than covered any depreciation on investments. The sum provided for depreciation and renewals for 1921 was £15 000, bringing the total to £67 319. In consequence of the strike in the early part of 1921, the results from the tramway were less satisfactory than formerly, and the dividend on the ordinary shares was reduced from 8 to 5 per cent., tax free.

To meet continuous demands for supplies of current additional generating and converting plant was being supplied. The additions included a water-tube boiler, one 5 000 kW turbo-alternator and additional rotary converters aggregating 3 000 kW. To provide the funds the Board took advantage of issuing £200 000 7 per cent. second debentures.

Mr. John G. B. Stone, who seconded the motion for the adoption of the report and accounts, said he had paid a visit to Madras. He found their relations with the Government and the Municipality were of the most cordial kind. He came away with the feeling that they had now a body of men whom it would take a very great deal to bring out on strike again. The trouble they were going to have was to meet the demands. The demand for both light and power was growing at a very rapid rate. There was one peculiarity in Madras which did not exist in many places, and that was the use of the fan, even in winter, practically without ceasing by day and even by night. During the day there was not only the heat to deal with, but the use of fans kept the mosquitoes off. As to their use at night he found that if he did not have the fan going, even in spite of mosquito curtains, the mosquitoes got in sometimes. There was not a great deal of industrial power at present in Madras, but that was probably due to the fact of there being no really cheap power available. Now that the company was in a position to offer cheap power, his impression was that they would find that their power load would grow very much.

Whitehall Electric Investments, Ltd.

Presiding at the annual meeting of Whitehall Electric Investments, Ltd., on Tuesday, the Hon. Clive Pearson (chairman of the company), in moving the adoption of the report and accounts, said that over a period of years Lord Cowdray, through one of his companies, the Whitehall Securities Corporation, Ltd., had acquired a controlling interest in various electrical companies in Mexico supplying certain large cities and their surrounding districts with light and power, and operating the tramway system in such cities. These enterprises were remodelled, and had been built up over many years into good properties ; they had been nursed through Mexico's troublous times, and were now in an established position, with steady earnings and good additional prospects still before them. An opportunity arose at the end of the war of purchasing from the Public Trustee the share control of the English company owning and operating the tramways and the power and light distribution system in Santiago, a city of 500,000 people, and the capital of Chile, which company had been controlled for some years before the war by the A.E.G. At the time of this purchase it was known that very considerable sums would have to be spent on extensions in order to develop the properties to their fullest extent, and to embrace not only the city of Santiago, but also the rich territory stretching to Valparaiso, the chief port of the country. It was, therefore, determined to form the Whitehall Electric Investments, Ltd., and to transfer to it the whole of the debentures and shares in the different electrical companies, both Mexican and Chilian, giving in exchange only ordinary shares in the Investment company, and to issue debentures and preference shares of this company to provide the cash required for the extension work.

A Fine Field for Business.

Upon acquiring the Chilian properties a complete examination of the position showed the existence of a very fine field for a large and satisfactory business. It was found that the development of considerable additional hydro-electric power was essential, and remodelling and extensions were required, both of the tramways in Santiago and the light and power distribution system. To provide the additional water power a controlling interest was obtained in and amalgamation effected with the Cia. Nacional de Fuerza Electrica, a company which had been formed and into which Chilian Nationals subscribed over half a million cash for the purpose of developing hydro-electric power at Maitenes, some thirty miles outside Santiago. The Cia. Chilena was thus inaugurated as the owners of hydro-

electric developments, and of a very large system of trams and light and power distributing facilities. It was earning a large immediate income in a field very favourable for the investment of additional capital to extend its activities. When the Maitenes water power development was completed the company would be enabled to fulfil the important contract it had entered into for the supply of power to the Government railways, the electrification of which was already in hand.

The Position in Mexico.

With regard to Mexico, in spite of all its misfortunes, political and financial, during the last nine years—it still continued one of the richest countries in the world with an unlimited future. Mexico had a population of some 15 000 000 of people, whose capacity for work and whose reputation for honesty must be regarded quite apart from the relatively small number of people who constitute the disturbing factor in the country. To enable the factories to work they required the services of the great utility companies for the supply of electric light and power. It was a noteworthy fact that during the whole of the disturbed period little or no damage had been done to any electric power and light plant throughout the Republic. The demand for the supply of electric energy was constant and growing. Referring to the company's Mexican investments, the chairman said the Tampico Company was formerly an English company, now in voluntary liquidation, owing to English income-tax. The port of Tampico had grown largely in the last few years, due to the oil industry having developed so materially in the district, and while there was a temporary lull, their profits for 1922 would not be as large as those of 1921, the company's record year, there seemed to be no reason why the earnings of this company should not before long again equal the 1921 figures, and, in fact, exceed them. So far as they were able to judge there was no reason why—in addition to the payment of its debenture interest and sinking fund, and dividend on its preference shares—it should not earn a reasonable dividend on its ordinary shares for the current year. The Puebla Company, which operated in the city of Puebla—the centre of the cotton industry in Mexico—was a Canadian company which was formed many years ago. The company supplied power over a large district, and Puebla was probably one of the best-lighted cities in the world. The water-power station at Tuxpango was now developed for 17 000 H.P., and was capable of developing 17 000 more. The total horse-power at present developed by the company at its three stations—Tuxpango, Portezuela, and St. Augustin was 26 000. The outlook for this company was good, and the earnings ought steadily to increase.

Electric Construction Co.

In the course of his address at the annual meeting of the ELECTRIC CONSTRUCTION Co. last Thursday Mr. Philip E. Beachcroft, who presided, said that the accounts submitted showed a reduction in net profit of only £425 compared with that of the previous year—a satisfactory result having regard to the prevailing conditions. The net revenue for the year amounted to £82 684, and after payment of various dividends £22 072 remained to be carried forward. In the balance sheet the item of properties, patents and goodwill stood at £350 705. Since the accounts were made up a careful valuation had been completed, from which it was evident that the value of buildings, plant and machinery and other fixed assets exceeded the amount in the balance sheet. The properties for many years had been maintained out of revenue at a high state of efficiency, and provision for depreciation had also been liberal. The directors, therefore, considered that the reference to patents and goodwill in the balance sheet should in future be eliminated. Orders since the beginning of the new financial year were 50 per cent. greater than in the corresponding period last year. Whether the improvement would be maintained he could not say, but the discontinuance of the engineers' strike should give the trade of the country a considerable impetus. Dealing with the general situation, the chairman said that, before the country could recapture its export business, lower costs of production were essential, and these could only be obtained by a lower standard of wages and salaries, by a lower margin of profit, and by increased output. Above all, there must be co-operation between capital and labour, for without it all efforts would be in vain. To that end he would counsel the adoption to a far greater degree than hitherto of the piecework system, which was not now regarded by labour with the same antagonism as formerly. If it were adopted, labour would procure week by week the fruit of its own effort without being dependent on profits, which were not ascertained for many months. An abstract of the accounts was given in our issue of June 9.

Anglo-Argentine Tramways.

Presiding at the annual meeting of the ANGLO-ARGENTINE TRAMWAYS Co., last week, Sir George A. Touche (the chairman) said he feared that the report for the year might have been received with some disappointment by the shareholders. Their total receipts were less by £135 000, and their total expenses more by £107 000. In 1920 the receipts from all sources were £4 413 164. In 1921 they were £4 277 600, a difference of £135 564. In his address last June he called attention to the manner in which the revenue for 1920 had benefited by the favourable exchange and the large credit for income tax, owing to the heavy payments for arrears of dividend on the first preference shares, and explained that such credits were windfalls not likely to recur. The difference in exchange alone represented a larger sum than the difference in net receipts, while income tax accounted for nearly as much as the reduction in receipts from all sources. The par rate of exchange for the Argentine gold dollar on London was 47·58d. Their remittances for the year totalled nearly £1 000 000, at an average rate of 45⅛. In 1920 the average rate was 58·89d, and they had thus lost heavily on the exchange.

When they separated the traffic receipts from the other credits there was some ground for encouragement. In his report a year ago the general manager estimated an increase of 5 per cent. in 1921. This estimate had proved accurate. The traffic receipts in 1920 were £4 000 741 ; in 1921 they were £4 203 369, an increase of £202 628. The traffic receipts were the backbone of their undertaking. Last year they carried nearly 90 000 000 more passengers than in 1916, and they ran nearly 7 000 000 more miles.

The total expenditure for the year amounted to £3 305 081, against £3 198 028 in 1920. Traffic expenses were £1 223 358, or £65 093 in excess of the previous year. Of this £57 218 represented increases in wages. Traction expenses were £644 724. These were governed by the cost of fuel. The traffic expenses in 1920 were £812 693. The sum of £433 481 was paid to the Municipality of Buenos Ayres for taxation. It consisted principally of the percentages on traffic receipts payable under the terms of the company's concession. The balance carried to the net revenue account was £972 519. They had paid the current year's dividend on the first preference shares, £176 000, leaving £143 531 undistributed. This enables them to satisfy 12 months arrears on the second preference shares to December 30, 1917, requiring £137 500, and left to be carried forward to 1922 £6 031. They had already paid one-half of this second preference dividend, and now recommended the payment of the second half. It was a question whether they should pay a full year's dividend on the second preference shares, or only a half-year's dividend. To pay the full year it was necessary to encroach, to a small extent, on the amount carried forward, which was reduced from £15 884 to £6 031. It went against the grain to do this, but the Board felt it to be desirable to prevent the arrears on the second preference shares from increasing. There were still four years of dividend in arrear on these preference shares, while the ordinary share capital of £3 250 000 had received no return since 1914. This was not a satisfactory position. The business should be self-supporting on a commercial basis. The city was supplied with the finest tramway service in the world. The gain to the Tramway Company was very disappointing. The present tariff arrangement was authorised in 1920, and was subject to review in 1923.

United River Plate Telephone.

At the annual meeting of the UNITED RIVER PLATE TELEPHONE Co. on Tuesday, the Chairman (Sir Frederick Green, K.B.E.), after an analysis of the report and accounts (given in our last issue), stated that they were paying a final dividend of 5 per cent. on 324 000 ordinary shares, making (with the interim dividend) a total of 8 per cent. for the year, and a dividend of 5 per cent. on 108 000 ordinary shares, both tax free, leaving £38 705 to be carried forward, against £38 367 in the previous year. He was sorry to say the Government had not yet given them permission to make the moderate increase in rates for which they petitioned in the spring of 1919. That attitude on the part of the Government, failing, as they thought, to recognise the present high costs of working a telephone business had been unfortunately reflected in the accounts, for there was no balance available for the usual reserve appropriation. The necessity for an increase was constantly being urged upon the authorities, and they would also lose no opportunity of bringing home to the Government and the public that although the company was only too anxious to provide all the telephone facilities needed, they were unfortunately unable to embark upon further considerable extensions until increased rates were forthcoming.

Extensions and Additions.

During the year they had completed extensions to many of their common battery manual exchanges, to the Rosario automatic exchange and to several magneto exchanges, as well as having opened two additional automatic installations in the City of Cordoba and one in Rosario. Most of that equipment was ordered shortly after the armistice, but manufacture had been slow, and it was only in the current year that they would reap the full benefit of that expenditure. The new plant had enabled them during 1921 to connect 13 672 new stations, making the total number connected 97 274, against 83 602 at the end of 1920. There were still a large number awaiting service, and they regretted that until the automatic exchanges were opened they should be able to do but little towards reducing the number. Last July they came into possession of the important Bahiense system, operating in the City of Bahia Blanca and neighbourhood, and they were now engaged in consolidating the system with their own. It had not, however, been possible yet to connect that south-western part of the Province of Buenos Aires to the Federal capital, though they hoped to be able to do so before long, and also other systems which were at present isolated. Though trade conditions in the Argentine were not of the brightest, the outlook from a telephone point of view was most encouraging, as was evidenced by the large number of the public still awaiting service. Notwithstanding the question of rates, their relations with the National Government and the Provincial Governments and the various municipalities continued to be cordial. The deputy chairman (Mr. Percy Cross) would leave for Buenos Aires in August, accompanied by Mr. Dawbarn, the London manager.

Sir John Gavey, whose health had made it necessary for him to relinquish the position of deputy chairman, retained his seat on the Board. With regard to the current year, he said they did not anticipate considerable difficulty in maintaining the dividend on the present capital; but the Argentine Government must recognise that the company could not embark on further extensions requiring fresh capital, having regard to increased wages and the high cost of material, unless adequate rates were permitted.

Globe Telegraph and Trust.

Sir John Denison-Pender, G.B.E., K.C.M.G., presided over the 49th ordinary general meeting of the Globe Telegraph and Trust Co., Ltd., on Tuesday and expressed his pleasure at being able to submit figures which exceeded those of last year. They were in no way due to a windfall, or any transitory cause. The year's total receipts, after deducting working expenses, amounted to £330 146, an increase over last year of £42 374. The directors recommended a final dividend of 3s. per share on the preference shares, making 6 per cent. (less tax), for the year, and of 5s. per share on the ordinary shares, making a total of 10 per cent. net. The company were thus paying the same rate of dividend to their ordinary shareholders as they did last year, but whereas last year they found it necessary to draw upon their reserve fund for contingencies to the extent of £10 000, this year not only did they not require to borrow anything from that fund, but they actually carried forward a surplus of over £20 000. The arrangement entered into about two years ago between the British Government and the Direct United States Cable Co. was supposed to expire on March 31, 1923, when their company would receive about £6 per share for its holding in that company, the shares having cost them £5 4s. 9d. each. When they received the money (about £90 000), they would be able to repay the £60 000 they had had to borrow owing to the fact that 6 000 of their new shares were held and not allotted, and they would have about £30 000 to invest. The income from their American investments showed a reduction in each instance, but in no case was that due to any diminution in the rate of dividend paid. On the other hand, they now received the benefit of a full year's dividend on their investment in the new issues of stocks and shares of the Eastern, Eastern Extension, and Western Union Telegraph Companies. That increase alone amounted to over £58 000, and entirely dwarfed the small losses referred to. While many first-rate industrial concerns which had held investments for many years past had been setting aside sums to meet depreciation, the present value of their company's securities showed an appreciation of over £2 000 000.

The report and accounts were unanimously adopted, and at an extra-ordinary general meeting new articles of association were approved.

Benn Brothers, Ltd., recommend a second interim dividend at the rate of 2½ per cent. per annum on account, payable on July 1.

Callender's Share and Investment Trust propose to pay an interim dividend of 4 per cent. (at 8 per cent. per annum), less tax.

The Aluminium Corporation proposes to increase its 6 per cent. first debentures from £250,000 to £500,000, and to redeem them in 1941 at a premium of £5 per cent.

The Canadian General Electric Company have declared a quarterly dividend of 1½ per cent. for the three months ending June 30, 1922, on the common stock.

The directors of the Barnsley and District Traction Company have declared a dividend of 15 per cent. on the ordinary shares for the past year. An issue is being made of 20 035 ordinary shares at par.

The net profit of the Para Telephone Company for 1921 was £2 482, plus £8 605 brought forward, making £11 087. A further dividend is announced of 3 per cent., making 6 per cent., free of tax, carrying £4 457 forward.

The accounts of Veritys Ltd. for 1921, after providing £2 783 for depreciation, show a net loss of £3 002, plus £6 300 for interim dividends paid during the year. After deducting credit balance of £1 656 brought in, a debit balance of £7 646 remains to be carried forward.

A special dividend of one-half per cent. has been declared on the common stock of the Manila Electric Corporation for the quarter ending June 30, payable on the 1st prox., and making with a regular quarterly dividend of 2 per cent. already announced, a total of 2½ per cent., or $2.50 per share.

The net profit of James Keith and Blackman Company for the year ended March 31 was £20 481. After providing for debenture interest and allowing for depreciation and reserves, with £12 575 brought in, the total is £33 056. It is proposed to pay a dividend on the ordinary shares of 7½ per cent., tax free, carrying forward £15 944.

The Victoria Falls and Transvaal Power Company announce a final dividend of 4 per cent., less tax, on the preference shares, making 10 per cent. for 1921 (the same), and also a dividend of 3 per cent., less tax, on the preference shares on account of 1922. The dividend on the ordinary shares for 1921 is 5 per cent., less tax (the same).

The net receipts of the Shropshire, Worcestershire and Staffordshire Power Company for the past year were £95 153. After deduction of administration and general expenses, debenture and loan interest, and adding £16 183 brought in, there remains £41 083. The directors propose dividends on the 7 per cent. preference and 6 per cent. preference shares for the year, leaving £27 272 to carry forward.

At the meeting of the Yorkshire (Woollen District) Electric Tramways, Ltd., last week, it was reported that the receipts for 1921 totalled £124 330. Deducting all expenses, including repairs and maintenance, debenture and other interest, and setting aside £15 000 to renewals fund, there remains £8 881, plus £9 356 brought in, making £18 237. It is proposed to place £5 000 to reserve and to carry forward £13 237.

The profits of Waygood-Otis, Ltd., for the year ended March 31, after providing for depreciation, amounted to £77 360 (against £83 069), and £27 980 was brought forward. A sum of £40 000 has been placed to reserve, £5 000 to pensions fund, and the directors propose a final dividend of 5½ per cent. on the ordinary shares, making 8 per cent. for the year, and a bonus of 2 per cent. A sum of £22 340 is carried forward. The dividend was 9 per cent. for the previous year.

The profit of Head, Wrightson & Co. for the year ended April 30, after providing for taxation, amounted to £51 163 (against £63 033), while £19 028 was brought forward. After providing for debenture interest, preference and interim dividend on the ordinary shares, etc., and placing £20 000 (against £30 000) to reserve for general purposes, there remains £27 889. A final dividend is proposed on the ordinary shares at the rate of 5 per cent., making 7½ per cent., less tax, for the year (the same), the amount carried forward being £16,544.

The report for 1921 of Richardsons, Westgarth and Company shows a profit, after providing for estimated liabilities to the Government, of £305 207, compared with £155 635 for 1920. The directors recommend the payment of two years' dividend on the preference shares up to April this year, and of 8 per cent. on the ordinary shares. The sum of £50 000 has been set aside for the development of the new department for the building of Diesel engines, £50 000 has been placed to reserve, £45 000 has been written off for depreciation, and £54 785 carried forward. The directors state that the financial position of the company is better and stronger than ever before in its history.

The report of Kidderminster and District Electric Lighting and Traction Company for 1921 shows that the net receipts of the lighting undertaking, including dividends, were £4 848, plus £35 brought forward, making £4 884. After deducting administration and general expenses and interest on temporary loans, there remains £2 888. The directors propose to pay a dividend of 2½ per cent. on the ordinary shares for the year, carrying forward £213. Kidderminster and Stourport Electric Tramway Company made a profit, after providing for renewals, of £2 149, plus £114 brought forward, making £2 264. A dividend at the rate of 3½ per cent. on the share capital absorbed £2 002, carrying forward £262.

Mr. F. A. Govett presided over the annual meeting of the Zinc Corporation last week, and stated that as he was not very hopeful of a rapid improvement in world conditions and he regarded it as the duty of the Board to preserve the company's resources as far as possible. They had an option to acquire about one-sixth interest in the Australian rights of the Elmore process, and they had recently acquired, at a depreciated price, about 45 000 shares in the parent company, the Chemical and Metallurgical Corporation. On the whole, they had confidence in the future of this branch of their industry. As to the Electrolytic Company, the full plant was expected to be in operation by next year, and the profits were estimated as likely to be sufficient to pay from 12½ to 15 per cent. on the ordinary stock which their company held.

The net profit of Edmundson's Electricity Corporation for the year ended March 31 last, after providing for income tax, mortgage and note interest and debenture stock charges, amounts to £31 369, as compared with £16 053 for 1921. With the balance of £14 143 brought forward the total profit available is £45 512, of which the directors propose to pay £30 000 in respect of dividends (and arrears) on the cumulative preference shares and a dividend of 3 per cent. on the non-cumulative preference shares, leaving £15 512 to be carried forward. During the year £56 100 of the 6½ per cent. three year notes have been paid off at a premium of £280 10s., leaving £18 000 outstanding. The directors intend to redeem these remaining notes when they fall due for repayment next February. In the meantime, they have arranged with the trustees to accept Government Bonds in lieu of prior lien debenture stock as collateral security for the notes, and the prior lien debenture stock has accordingly been released and cancelled.

The report of the South Wales Electrical Power Distribution Co. for the year ending December last shows that the units sold amounted to 46 533 098, a decrease of 10 510 540, as compared with the previous year. This decrease is attributed largely to the three months' coal strike and also to difficulties with the plant which have now been remedied. The commercial side of the

undertaking is operated by the Treforest Electrical Consumers' Co., and after payment of all working expenses there is a credit balance from that company of £35 294, which, with £4 417 brought forward, makes available a balance of £39 711. Deducting the interest on the two classes of debenture stock of the company and depreciation on the new plant, £3 653 remains to be carried forward. The directors state that the agreement between the company and the Treforest Electrical Consumers' Co. has been revised, and that the company's Bill adjusting the ordinary share capital and containing other provisions advantageous to the shareholders has been passed by the House of Lords and read a second time in the House of Commons. Mr. W. Gascoyne Dalziel, chairman of the company, since 1907, has resigned the chairmanship, to which Mr. Westgarth Forster Brown has been elected. Mr. Dalziel still remains a member of the board.

The working of LISBON ELECTRIC TRAMWAYS, LTD., for the past year, after deducting interest and amortisation due on the debentures of the "Companhia Carris de Ferro de Lisboa" and after the payment of £24 415 interest on and redemption of debentures of the Lisbon company, and also payment of London expenses and directors' remuneration, shows a loss of £29 184. To this sum is added the balance of loss brought forward from last year, £19 271, which gives the sum of £48 455 to be carried forward to the debit of next year's profit and loss account. During the past year the tramways have carried 83 626 312 passengers with receipts of Esc. 11 102 068, as compared with 80 567 940 passengers and receipts of Esc. 6 088 286 in the preceding year. The working of the tramway was again adversely affected by the stoppage and restriction of the service owing to strikes and other disturbances. The rate of exchange at the beginning of the year stood at 6⅜d. per Escudo and at the close of the year had fallen to the low figure of 4 7/16d. This materially increased the working expenditure and especially the cost of all supplies purchased outside Portugal. No increase in the fares was obtained during the period under review, although constant applications were made both to the Government and the Camara, in view of the operating losses. A Commission was appointed in July last by the Portuguese Government to inquire into the matter, but its recommendations were not carried out as the Camara withheld its approval, and it was not until the present year that an agreement was at last concluded, to enable an increase in the tariffs to be made, which it is hoped will put the company's future operations on a sounder basis.

New Companies.

E. N. Bray.

E. N. BRAY, LTD. (182 489).—Private company. Reg. June 15. Capital, £3 000 in £1 shares. Electrical engineers, contractors and manufacturers, etc. First directors: E. N. Bray, E. S. Dawn and R. C. Court. Secretary: E. S. Dawn. Solicitors: Warrens, 5, Bedford Square, W.C.1.

Johnson, Savage & Co.

JOHNSON, SAVAGE AND CO., LTD. (182 492).—Private company. Reg. June 15. Capital, £500 in £1 shares. Electricians, mechanical engineers, suppliers of electricity, etc. Provisional directors: R. M. Johnson and E. M. Savage. Secretary: E. M. Savage. Reg. office: 1, Argyle Street, Oxford Circus, W.1.

Electrico.

ELECTRICO, LTD. (182 506).—Private company. Reg. June 16. Capital, £6 000 in £1 shares. Manufacturers of and dealers in electrical goods, etc. Permanent directors: E. Brontman (man. dir.), A. E. Glassey, F. R. Ozzard, H. Kirby and J. Brewer. Sec.: H. G. Perrett. Reg. office: 105, Old Christchurch Road, Bournemouth.

British Radiophone.

BRITISH RADIOPHONE, LTD. (182 427).—Private company. Reg. June 13. Capital, £2,500 in £1 shares. Manufacturers of and dealers in apparatus of all kinds relating to wireless telephony and telegraphy; to deal with land and submarine telegraphs, etc. First directors: N. de M. Watsham and A. H. S. MacCallum. Reg. office: 33, King-street, Covent Garden, W.C.

Dundee Electrical Repairs Co.

DUNDEE ELECTRICAL REPAIRS CO., LTD. (12 256).—Private company. Reg. in Edinburgh June 12. Capital, £3 000 in £1 shares. To carry on the business of repairing all classes of electrical plant and machinery, etc. First directors: W. Brand, W. A. Andrew, T. Innes, J. P. Andrew, and J. Taylor. Secretary: Wm. A. Andrew. Reg. office: Graham Street, Dundee.

R. Bennett.

R. BENNETT, LTD. (182 399).—Private company. Reg. June 12. Capital, £1,500 in £1 shares. To adopt an agreement with R. T. Bennett; to lease property and to erect thereon buildings: to contract for the supply of heating apparatus, electric light and bell installations, etc. Permanent directors: R. Bennett and G. P. Barnes. Reg. office: Colliers Water Lane, Thornton Heath.

W. H. Sugden & Co.

W. H. SUGDEN AND CO., LTD. (182 446).—Private company. Reg. June 13. Capital, £2 500 in £1 shares. To adopt an agreement with W. H. Sugden, and to carry on the business of electrical, mechanical and general engineers, etc. First directors: W. H. Sugden (permanent managing director), and Mrs. D. E. Sugden. Secretary: H. C. Mundy. Reg. office: Glenny Road, Barking.

Bedford Electrical & Radio Co.

BEDFORD ELECTRICAL AND RADIO CO., LTD. (182 405).—Private company. Reg. June 12. Capital, £1 000 in £1 shares. To acquire business of electrical engineers, builders, house decorators and automobile engineers carried on by A. J. E. Osbourn, and to carry on the business of electricians, manufacturers and repairers of or dealers in mechanical and electrical appliances, etc. First directors: A. J. E. Osbourn and C. T. Morris. Reg. office: 22, Campbell Road, Bedford.

Evered & Co.

EVERED AND CO., LTD. (182 412).—Private company. Reg. June 12. Capital, £50 000 in £1 shares. To acquire all or part of the undertaking and assets of Evered and Co., Ltd., of London, Birmingham and elsewhere, and to carry on business of the brass-founders, coppersmiths, hardware merchants and factors, manufacturers of electric light and power fittings and apparatus, lamps, metal work, etc. Directors: J. H. Wilson, H. E. Wilson, E. A. Wilson and S. Evered.

Loco and Auto Economy Accessories.

LOCO AND AUTO ECONOMY ACCESSORIES, LTD. (182 377).—Private company. Reg. June 9. Capital, £10 000 in £1 shares. To acquire from Harvey and Spencer and A. H. Emons, certain existing sales rights, to manufacture and deal in machinery, apparatus and implements and to carry on the business of mechanical engineers, electricians, founders, etc. The Directors are: A. H. Emons, L. C. Harvey, and F. B. Spencer. Secretary, W. Peskett. Reg. office: 25, Victoria Street, Westminster, S.W.1.

Specialities (Liverpool).

SPECIALITIES (LIVERPOOL), LTD. (182 418).—Private company. Reg. June 12. Capital, £2 000 in £1 shares. To take over the whole or part of property, assets and goodwill of H. F. Kerley and Winifred E. Kerley, trading at 45, Seel Street, Liverpool, as the Electrical Specialities Co., and to carry on the business of manufacturers, importers and exporters of and dealers in electric lamps, shades and electrical accessories. Permanent directors: H. F. Kerley (managing director), and Winifred E. Kerley.

Verdun Cutts & Co.

VERDUN CUTTS AND CO., LTD. (182 419).—Private company. Reg. June 12. Capital, £10 000 in £1 shares. To acquire business of a consulting and contracting engineer and electro-metallurgist carried on by V. O. Cutts at Sheffield, as Verdun Cutts and Co., and to carry on the business of electrical and mechanical engineers, founders, etc. Directors: C. A. Longbottom (chairman), V. O. Cutts (permanent man. director), D. Flather and D. E. Beardshaw. Secretary: A. E. Cutts. Reg. office: Town Hall Chambers, 87, Fargate, Sheffield.

Sir William Prescott & Sons.

SIR WILLIAM PRESCOTT AND SONS, LTD. Reg. June 15. Private company. Nominal capital, £10 000 in £1 shares. To acquire, work and otherwise deal with contracts and property of all kinds, including railways, rolling stock, tramways, British and Colonial contracts, electrical generation, traction and supply. Signatories to the Memorandum of Association: Sir William Henry Prescott, Sir L. Stanley Johnson. First directors: Major Sir William H. Prescott (chairman), Lieut.-Col. A. E. Prescott (vice-chairman), Sir L. Stanley Johnson, Dr. R. Marshall, and R. S. Prescott. Reg. office: 146, Bishopsgate, E.C. File number: 182 482.

Claim for Electric Lamps.

In the Shoreditch County Court, the Weston Electric Lamp Co. sued Mr. Evans, of Llanelly, to recover £2 5s., the price of six 250 V lamps.

A preliminary defence was raised that the contract was made in Llanelly, and that therefore the Shoreditch Court had no jurisdiction, but Judge Cluer held that he must have that proved as a fact.

The solicitor for the defendant said his client considered it inadvisable to waste time and money in coming to London, and plaintiffs' manager proved the receipt of the order and the despatch of the lamps on December 12. It was not until March that they heard anything from defendant, who then said that he had never had the goods. Judgment was given for plaintiffs for the amount claimed, and costs.

Foundry Trades Exhibition.

At this Exhibition, which is being held at the Bingley Hall, BIRMINGHAM, from June 15 to 24 inclusive, practically every phase of foundry plant is being shown. About 1 000 tons of machinery are installed and between 300 and 400 H.P. is supplied to the working exhibits. There are 120 exhibits, which include electric furnaces, moulding machines, foundry equipment, refractories, etc.

Interesting features of the Exhibition are the competitions for foundry employees in core-making, moulding and pattern-making, and in an annexe a cinema hall is established for the purpose of exhibiting appropriate films. VICKERS, LTD., who claim to be pioneers in the use of cinematography for illustrating their manufactures, show five films, all made by the photographic department of the firm. These are: Vickers' Sheffield peace products: (1) motor car chassis frames, etc.; (2) crucible steelfoundries, etc.; Barrow shipbuilding works, (3) launch and trials of a battleship, airship R.80, Vickers aircraft, etc.; (4) Vickers' Ward End (Birmingham) works during war; and (5) Wolseley works during war.

Tenders Invited and Accepted.

UNITED KINGDOM.

PORTSMOUTH BOARD OF GUARDIANS, June 28:—Electrical fittings for three months. Particulars from the Clerk, Mr. H. C. Morrell, St. Michael's Road.

COMMISSIONERS OF H.M. WORKS, June 30.—Incandescent electric lamps. Particulars from the Controller of Supplies, H.M. Office of Works, King Charles Street, Westminster, London, S.W.1.

GLASGOW CORPORATION, June 30.—Electric wiring and fitting of Belvedere Hospital, London Road. Specifications, etc., from the City Electrical Engineer, 75, Waterloo Street, Glasgow.

MANCHESTER ELECTRICITY COMMITTEE, June 30.—Two 3 000 kVA three-phase weather proof type transformers and two 3 000 kVA three-phase indoor type transformers. Specifications from Mr. F. E. Hughes, Town Hall, Manchester.

THE COMMISSIONERS OF HIS MAJESTY'S WORKS, July 4.—(1) Electrical and (2) mechanical engineering labour in daywork. Forms of tender, etc., from the Contracts Branch, H.M. Office of Works, Westminster, S.W.1.

CHEADLE AND GATLEY URBAN DISTRICT COUNCIL, July 10.—a.c. meters (2½ to 20 A) and m.d. indicators (3 hectowatts to 5 kilowatts). Particulars from Mr. C. H. Wordingham, 11, Mosley Street, Manchester, or 7, Victoria Street, Westminster, London, S.W.1.

EDINBURGH CORPORATION, July 11.—Wheels and axles for 50 electric tramcars. Specification, etc., from the Tramways Manager, 2, St. James Square, Edinburgh.

AUSTRALIA.

COMMONWEALTH OF AUSTRALIA, June 23.—Telephone and telegraph instruments and parts, switchboard, wire, etc. Particulars from Supply Officer, Room 101, Australia House, Strand, London, W.C.

COMMONWEALTH OF AUSTRALIA, June 30.—Telephone and telegraph instruments and parts, wire protector apparatus, subscribers' equipment. Particulars from Supply Officer, Room 101, Australia House, Strand, London, W.C.

COMMONWEALTH OF AUSTRALIA, July 7.—Telephone subscribers' equipment. Particulars from Supply Officer, Room 101, Australia House, Strand, London, W.C.2.

POSTMASTER-GENERAL'S DEPARTMENT, MELBOURNE. July 11*.—4 000 pairs of protectors (Schedule No. 26); covered wires (Schedule No. 21); telephones, calling dials and switches (Schedule No. 34).

COMMONWEALTH OF AUSTRALIA, July 14.—Telephone subscribers' equipment. Particulars from Supply Officer, Room 101, Australia House, Strand, London, W.C.2.

AZORES.

MUNICIPAL AUTHORITIES OF PONTA DELGADA IN THE AZORES, July 3.*—Hydro-electric plant for supplying electric light and power to the city.

BULGARIA.

DIRECTORATE GENERAL OF BULGARIAN RAILWAYS AND PORTS, June 30.—*Electric travelling platforms for locomotive repair shops.

INDIA.

HIGH COMMISSIONER FOR INDIA, July 14.—(1) Cable, underwater, unarmoured, single wire, brass taped, G.P.; (2) cable, five wire, V.I.R. insulated and lead sheathed; (3) braided wire for crossings over power circuits. Particulars from the Director General, India Store Department, Belvedere Road, Lambeth, S.E.1.

SOUTH AFRICA.

A specification has been received from H.M. Senior Trade Commissioner at JOHANNESBURG in connection with a call for tenders issued by the Rand Water Board for the supply of electric cable, junction boxes, etc., and may be inspected at the Department of Overseas Trade on application to Mr. Fagan, Room 49.

AYLESBURY TOWN COUNCIL have accepted the tender of the British Thomson-Houston Co. for a turbo alternator at £10 302.

DOUGLAS (Isle of Man) Town Council has accepted the tender of Siemens Bros. and Co. for underground mains and accessories at £8,234 4s.

BLACKPOOL Town Council have accepted the following tenders:—The General Electric Co., switch gear cubicles; Peter Brotherhood Ltd., the erection of a cooling tower in connection with the town's electricity extensions.

LONDON COUNTY COUNCIL have accepted the tender of the English Electric and Siemens Supplies, Ltd., for the supply of electric lamps for the ensuing 12 months. The contract covers the supply of Siemens traction type lamps for tramcar lighting throughout the L.C.C. system, standard vacuum and gas filled lamps, and automobile lamps.

* Particulars from the Department of Overseas Trade.

Arrangements for the Week.

FRIDAY, JUNE 23rd (to-day).

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

9.30 *a.m.* Meeting of the Council in the Grand Theatre, Wolverhampton.

10.30 *a.m.* Annual general meeting in the Grand Theatre, Wolverhampton.

Afternoon. Visit to Wolverhampton Corporation Electricity Generating Station, Commercial Road, when the president (Mr. S. T. Allen) will personally welcome members.

PHYSICAL SOCIETY OF LONDON.

5 *p.m.* At the Imperial College of Science, South Kensington, London.

1. "An Experiment on Molecular Gyrostatic Action," by Mr. J. W. Fisher, B.Sc.

2. "On the Viscous Properties and Molecular Dimensions of Silicane," by Prof. A. O. Rankine, D.Sc., and Mr. C. J. Smith, B.Sc.

3. "The Pressure-Gradient in Liquids Flowing through Cones," by Mr. W. N. Bond, M.Sc.

4. Demonstration of "a Mercury-Drop Method of Producing Visual Effects by means of Sound," by Dr. E. E. Fournier d'Albe.

MONDAY, JUNE 26th.

SOCIÉTÉ DES INGÉNIEURS-CIVILS DE FRANCE (BRITISH SECTION).

5.30 *p.m.* At the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1. Paper on "The Rhine Lateral Canal," by Monsieur A. Antoine.

TUESDAY, JUNE 27th.

THE INSTITUTION OF CIVIL ENGINEERS.

8.30 *p.m.* At Great George Street, London. Annual Conversazione.

Electrical Imports and Exports.

IMPORTS.—The following are official values of electrical machinery, apparatus and material imported into this country (*a*) during May, 1922, and (*b*) the aggregate figures from January 1 to May 31, with increase or decrease compared with corresponding periods of 1921:—

Electrical machinery, (*a*) £98 991 (increase £5 369), (*b*) £549 503 (increase £156 808); telegraph and telephone cables, submarine, nil; other than submarine, (*a*) £2 675 (decrease £3 480), (*b*) £14 831 (decrease £28 668); telegraph and telephone apparatus, (*a*) £18 932 (decrease £9 395), (*b*) £70 562 (decrease £83 245); other electrical wires and cables, rubber insulated, (*a*) £10 565 (increase £9 451), (*b*) £47 949 (increase £36 213); with other insulations, (*a*) £4 733 (decrease £7 195), (*b*) £23 687 (decrease £31 240); carbons, (*a*) £4 010 (decrease £4 534), (*b*) £15 909 (decrease £33 619); glow lamps, (*a*) £10 748 (decrease £15 250), (*b*) £73 893 (decrease £52 828); arc lamps and electric searchlights, (*a*) £7 (decrease £2), (*b*) £72 (decrease £5 572); parts of arc lamps and searchlights (other than carbons), (*a*) £663 (decrease £2 250), (*b*) £4 215 (decrease £4 750); batteries, (*a*) £5 972 (increase £8 426), (*b*), £119 487 (decrease £10 438); meters and electrical instruments (commercial and scientific) and electricity meters, (*a*) £8 862 (decrease £6 074), (*b*) £27 862 (decrease £72 134); switchboards, (*a*) nil (decrease £3 115), (*b*) £1 519 (decrease £2 872); other electrical goods and apparatus, (*a*) £40 977 (decrease £2 044), (*b*) £216 967 (decrease £205 671). Total of electrical machinery, apparatus and material (other than uninsulated wire), (*a*) £207 155) decrease £27 488), (*b*) £1 074 859 (decrease £365 147).

EXPORTS.—The exports of electrical machinery, apparatus and material (*a*) during May, 1922, and (*b*) from January 1 to May 31, with increase or decrease compared with corresponding periods of 1921, were as follows:—

Electrical machinery, (*a*) £296 287 (decrease £163 338), (*b*) £2 183 170 (increase £45 977); including railway and tramway motors, (*a*) £9 031 (decrease £24 644), (*b*) £67 739 (decrease £48 532); other generators and motors, (*a*) £153 872 (decrease £97 777), (*b*) £1 155 325 (decrease £23 667); and electrical machinery unenumerated, (*a*) £133 384 (decrease £40 897), (*b*) £960 106 (increase £118 176); telegraph and telephone cables, submarine, (*a*) £25 765 (decrease £781 325), (*b*) £131 036 (decrease £1 350 935); other than submarine, (*a*) £43 172 (decrease £84 903), (*b*) £250 721 (decrease £485 208); telegraph and telephone apparatus, (*a*) £161 564 (decrease £10 078), (*b*) £869 542 (increase £121 579); other electrical wires and cables, rubber insulated (*a*) £50 277 (decrease £61 962), (*b*) £245 781 (decrease £523 035); with other insulations, (*a*) £63 784 (decrease £127 514), (*b*) £484 810 (decrease £546 798); carbons, (*a*) £4 889 (increase £1 755), (*b*) £20 347 (decrease £26 423); glow lamps (*a*) £32 730 (decrease £14 068), (*b*) £168 850 (decrease £69 590); arc lamps and searchlights, (*a*) £589 (decrease £2 333), (*b*) £3 843 (decrease £3 055); parts of arc lamps and searchlights (other than carbons), (*a*) £1 948 (increase £1 677), (*b*) £3 886 (increase £592); batteries, (*a*) £47 037 (decrease £24 871), (*b*) £194 940 (decrease £168 880); electrical instruments (commercial and scientific) and electricity meters, (*a*) £20 583 (decrease £26 144), (*b*) £155 071 (decrease £51 321); switchboards, (*a*) £8 251 (decrease £7 575), (*b*), £147 301 (increase £61 908); other electrical goods and apparatus, (*a*) £92 141 (decrease £82 508), (*b*) £511 136 (decrease £565 675). Total of electrical machinery, material and apparatus, other than uninsulated wire, (*a*) £849 017 (decrease £1 394 187), (*b*) £5 370 434 (decrease £3 560 864).

COMMERCIAL INTELLIGENCE.

County Court Judgments.

[NOTE.—The publication of extracts from the "Registry of County Court Judgments" does not imply inability to pay on the part of the persons named. Many of the judgments may have been settled between the parties or paid. Registered judgments are not necessarily for debts. They may be for actions. But the Registry makes no distinction of the cases. Judgments are not returned to the Registry if satisfied in the Court books within twenty-one days.]

BERG, J. AND CO., 169, City Road, E.C., electrical accessories manufacturers. £16 5s. 7d. April 21.

BRASON AND FINDLEY, 34, Laygate, South Shields, electrical engineers. £15 2s. 10d. April 19.

CARTER (HUBERT D.) (BANGOR) LTD., registered office, Accountancy Offices, Castle Street, Conway, electrical contractors. £37 2s. April 20.

CARTER, T. J., 16, Durngate Street, Dorchester, electrical engineer. £14 13s. 6d. April 24.

GIBBONS, A. R., 8, The Parade, New Eltham, electrical engineer. £16 8s. 8d. April 25.

HERBERT, R., 337A, Norwood Road, S.E., electrician. £12 5s. April 7.

JERRARD, Frank, 57, Church Street, Eastbourne, electriciam. £10 13s. 10d. April 27.

NORMAN JOHNSON AND CO., Baker Street, Enfield, electrical engineers. £26 10s. 3d. April 18.

STAMFORD BRIDGE ELECTRICAL MECHANICAL ENGINEERING CO., 495, Fulham Road, engineers. £38 5s. 4d. April 4.

WOOD, Harold, Old Manor House, Oak Lane, Bradford, electrical engineer. £13 3s. 10d. April 20.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

BURKE ELECTRICAL MANUFACTURING CO., LTD., London, S.W.—Reg. June 10, debenture, to J. Bibby, 36 Kingsway, W.C., general charge.

COATES AND CO. (SHEFFIELD), LTD., electrical engineers.—Reg. June 12, £6 500 debentures; general charge. *Nil. June 6, 1922.

HINDHEAD AND DISTRICT ELECTRIC LIGHT CO., LTD.—Reg. June 12, £100 debentures, part of amount already reg.; general charge. *£4,650. August 9, 1921.

MIDLAND ELECTRIC LIGHT AND POWER CO., LTD., London, E.C.—Reg. June 10, £20 000 debentures, present issue £14 000; general charge. *£20 000. March 4, 1921.

Satisfactions.

EDMUNDSON'S ELECTRICITY CORPORATION, LTD., London, S.W.—Satisfaction reg. June 9, £100 000, reg. April 29, 1920.

London Gazette.

Companies Winding Up.

THE CORONA LAMP WORKS, LTD. Registered office, 10, Ascham Street, Kentish Town, Middlesex. Winding up order, June 13.

GILLITT, S., AND CO., LTD. Registered office, 33, Groat Market, Newcastle-upon Tyne. Winding-up order, June 15.

Companies Winding-up Voluntarily.

SPLITDORF ELECTRICAL COMPANY OF LONDON, LTD.—H. J. Hinley, 162, Great Portland Street, London, appointed liquidator. Particulars of claims to the liquidator by July 5.

KEYNSHAM ELECTRIC LIGHT AND POWER CO., LTD. (in voluntary liquidation). Meeting of creditors will be held at 28, Baldwin Street, Bristol, on Tuesday, June 27, at 12 noon. Particulars of claims to the liquidator, Arthur Collins, 28, Baldwin Street, Bristol, by July 31.

Bankruptcy Information.

BROWN, Leslie, The Street, Frensham, Surrey, electrician. Receiving order, June 13. Creditor's petition. First meeting, June 26, 12.30 p.m., 29, Russell Square, W.C.1. Public examination, July 4, 11.30 a.m., Guildhall, Guildford.

GRIEVE, Gideon George, and MANGES, Archibald Arthur, in co-partnership at 14, West Bute Street, late 236, Bute Street, Cardiff, under the style of THE UP-TO-DATE ELECTRICAL AND MECHANICAL ENGINEERS. First meeting, June 27, 11.30 a.m., 34, Park Place, Cardiff. Public examination, July 5, 2.30 p.m., Law Courts, Cathays Park, Cardiff.

HOGG, George James (trading as F. HOGG AND CO.), 66, Waterloo Road, Smethwick, electrical engineer. First meeting, June 23, 11 a.m., Official Receiver's Office, Ruskin Chambers, 191, Corporation Street, Birmingham. Public examination, July 7, 11 a.m., Law Courts, Lombard Street West, West Bromwich.

ROGERS, Philip Marsden, Great Darkgate Street, Aberystwyth, as the LONGBRIDGE ENGINEERING CO., electrical engineer. Receiving order, June 14. Debtor's petition.

Notices of Dividends.

CAMP, William, Carr Lane, Slaithwaite, near Huddersfield, under the style of WILLIAM CAMP AND CO., electrical engineer. First and final, payable June 27, at Official Receiver's office, 12, Duke Street, Bradford.

ROTHWELL, Peter, trading at 64, Higher Bridge Street, Bolton, in partnership with P. A. Rothwell (a minor), under the style of P. A. ROTHWELL AND CO., electrical engineer. Amount per £, 6s Composition (first instalment) payable June 28, at Official Receiver's Offices, Byrom Street, Manchester.

Notices of Intended Dividends.

HALLETT, Graham Moore, 7, King Street, Frome, electrical engineer. Last day of receiving proofs, July 1. Trustee, J. P. Emett, 18, Nicholas Street, Bristol.

MAYNER, Robert Victor, 62, Harris Street, Peterborough, late Narrow Street and Wentworth Street, Peterborough, electrical engineer. Last day for receiving proofs, July 7. Trustee, J. O. Morris, 5, Petty Cury, Cambridge.

RIDGWAY, Fred (separate estate), in co-partnership with Thomas Tynan, at 21, Bowling Old Lane, Bradford, under the style of RIDGWAY AND TYNAN, electrical engineer. Last day for receiving proofs, July 5. W. Durrance, trustee, 12, Duke Street, Bradford.

TYNAN, Thomas (separate estate), co-partnership with Fred Ridgway, at 21, Bowling Old Lane, Bradford, under the style of RIDGWAY AND TYNAN, electrical engineer. Last day for receiving proofs, July 5. W. Durrance, trustee, 12, Duke Street, Bradford.

Dublin Gazette.

PORTARLINGTON ELECTRIC LIGHT AND POWER CO., LTD. A petition for winding up has been presented to the Court by Patrick Joseph Weymes, a contributory of the company. Wm. Smyth and Son, solicitors for the petitioner, 29, Lower Gardiner Street, Dublin.

Bankruptcy Proceedings.

COUPE, George Francis, 2, Spring Gardens, Stockport, Cheshire, electrical engineer. At his public examination debtor was closely questioned regarding some of his affairs, and was ordered to file a cash account from March, 1921, up to the date of the proceedings. The statement of affairs showed liabilities of £599, and there was a deficiency of £538. Debtor attributed his failure to bad trade and insufficient knowledge of the business. He commenced business as an electrical engineer in May, 1920, his father paying accounts to the extent of £100. He said that he had not sufficient experience to do the work himself, and had to rely on workmen. The examination was adjourned.

HOPKINS, John Howard (formerly trading as the ELECTRICAL MAINTENANCE CO.), 57, Castellaine Mansions, Maida Vale, W. The affairs of this debtor, who was adjudged a bankrupt on December 15 last, came before the London Bankruptcy Court on Friday on the hearing of his application for an order of discharge. The Official Receiver reported that a proof of debt for £9 562 had been lodged in respect of the only claim returned by the debtor as expected to rank. Two disputed claims aggregating £5 610 were returned in the statement of affairs as not expected to rank and no proofs had been lodged in respect of them. No available assets were disclosed by the debtor and only £9 19s. 1d. was realised. In July 1918, with a capital of £1 000, the debtor began business as an electrical engineer at 87, Shaftesbury Avenue, W.C., under the style of the Electrical Maintenance Co., and in March of the following year he was joined in partnership by one C. A. Hall, who introduced capital to the amount of £3 000 into the business

which was continued from the same address until August, 1919. It was then removed to 140, Wardour Street, W. In September 1920 the partnership was dissolved owing to disagreements between the partners and the debtor took over and continued the business and agreed to pay his late partner for his interest £5 000, payable as to £500 down and as to the balance by instalments of £40 a week. In December, 1920, a meeting of creditors was held when the debtor executed a deed of assignment but the petitioning creditor refused to join in the deed. The debts of the assenting creditors amounted to £20 000 and dividends aggregating 2s. in the £ had so far been paid. Afterwards the debtor was for a time engaged by the trustees in the realisation of the assets and he attributed his failure to lack of capital and to ignorance regarding one branch of the business. A complete set of books of account had been kept before the execution of the deed of assignment; they were in order and profit and loss accounts and balance sheets were prepared every six months from July 1918 until the date of the deed. The unsecured liability represented the claim of the petitioning creditor for cash advanced. The only offence reported by the Official Receiver was the insufficiency of the assets to pay 10s. in the £ to the unsecured creditor and the Registrar granted the discharge subject to a suspension of four weeks.

THE MAXIM LAMP WORKS, LTD., Maxim Works, Canonbury Road, Highbury, N. In this compulsory liquidation the Official Receiver has now issued a summary of the statement of affairs which discloses liabilities £11 050 of which £4 987 are returned as expected to rank, and assets £502 after providing for the claims of debenture holders and of preference creditors. A deficiency of £4 485 is accordingly disclosed with reference to the creditors while in relation to the shareholders a total deficiency of £9 485 is shown. The Maxim Electrical Co., Ltd., was formed in 1904 with the object of carrying on business as manufacturers of electric lamps. In March 1908 Mr. J. F. Poynter was appointed receiver and manager by the debenture holders in respect of their debentures for £15 000. Poynter as receiver and manager continued to carry on the business until early in 1910 with the assistance of Mr. F. Taussig, who advanced £2 000. Early in 1910 arrangements were made with the approval of the debenture holders to form a new company to acquire the assets of the old company. According to Mr. Poynter the purchase agreement provided for a purchase price of £2 220 payable as to £720 in cash and as to the balance by the allotment of 1 500 fully paid preference shares of £1 each in the new company. At the end of 1914 the company became short of working capital and borrowed from the Imperial United Lamp Co., Ltd., a sum of £1 000 for which a debenture was given. On October 18, 1915, a further debenture for £500 was issued to them as additional security. At the time that the first debenture was issued to them that company agreed to take up in future practically the whole of the company's output at a certain price, the contract stipulating that any increase in the cost of production should be borne proportionately by the Imperial Co. and providing for arbitration in the event of any dispute arising. As time progressed cost of production rose as the result of the War, but it is alleged that the Imperial Co. failed to pay the whole of their share of the increase with the result that in February 1918 the company refused to make further deliveries. The Imperial Co. thereupon began a debenture action against the company which was, however, withdrawn on the company paying off their debentures amounting to £1 500 out of moneys advanced by Mr. Poynter. Arbitration proceedings were then begun under which the company claimed £5 527 representing the difference in the price of lamps due from the Imperial Co. These proceedings lasted 18 months and eventually the award which was made in April 1920 provided that the company should pay the Imperial Co. £783 in full settlement of the latter's counterclaim for £3 731 for raw material supplied and £200 costs and should supply the Imperial Co. with 2 000 lamps a week at a certain price for a period of 18 months from January 2, 1920. Mr. Poynter says that the Imperial Co. did not take delivery under this award and in consequence the company in September, 1920, again approached the arbitrators with a claim for damages amounting to £3 500. No further proceedings were, however, instituted. The company about this time found itself burdened with a large number of lamps with little hope of disposing of them owing to the depression in trade which prevailed. On April 8, 1918, debentures for £3 000 were issued to Mr. Poynter in respect of cash advanced and personal guarantees given and subject to the bank's prior charge. Certain of these debentures were afterwards transferred and on July 28 last Mr. Poynter appointed as receiver and manager on his behalf Mr. Alfred Tosh, accountant, 75, Canonbury Road, N., and that gentleman is now carrying on the business. Mr. Poynter says that in his opinion the failure of the company is due to the unprofitable transactions with the Imperial Co. which had the effect of causing the company to incur great expense in the production of lamps which were eventually left on its hands with little prospect of disposal. The Official Receiver concurs in this view but is of the opinion that the company has been hampered by lack of working capital from its inception and that its affairs have been mismanaged. The liquidation remains in the hands of the Official Receiver

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by MESSRS. MEWBURN, ELLIS & CO., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

COMPLETE SPECIFICATIONS:

145 470 SIEMENS-SCHUCKERTWERKE GES. Electric induction motors. (29/1/18.)
173 247 WADE, H. (Vanadium Corporation of America). Power control apparatus for electric furnaces. (30/6/20.)
173 251 BRYDON, S., and CUMMINGS, E. Galvanic batteries or cells. (3/7/20.)
158 217 MEYER AKT.-GES., DR. P. Alternating current meters according to the Ferraris principle. (27/1/20.) (Addition to 148 576.)
173 268 MARINO, Q. Electrolyte for use in the electro-deposition of metals and metallic alloys. (25/8/20.)
151 591 SOC. DE L'ACCUMULATEUR TUDOR. Containers of electric accumulator cells. (27/9/19.)
173 272 SIEMENS BROS. AND CO., LTD., and FERREIRA, L. DE M. G. Electric signalling arrangements for use on railways and for other purposes. (27/8/20.)
173 278 TAYLOR, A. M. Means for and methods of earthing the neutral point of three-phase systems. (30/8/20.)
173 284 WESTERN ELECTRIC CO., LTD. (Western Electric Co., Inc.). Ringing-arrangement for carrier wave-signalling system. (16/9/20.)
151 610 NEGROMANTI, A. Device for heating by electricity. (19/9/19.)
173 291 CROMPTON AND CO., LTD., and JONES, W. F. Electric resistances. (22/9/20.)
173 292 CROMPTON AND CO., LTD., and JONES, W. F. Electric resistances. (22/9/20.)
173 293 CROMPTON AND CO., LTD., and JONES, W. F. Electric rheostats or resistances. (22/9/20.)
151 929 SIEMENS AND CO., GEB. Process for the manufacture of sliding and pressure contacts for electric purposes. (30/9/19.)
163 675 VICLET, R. A. L. Dynamo-electric machine commutators and like electrical apparatus. (21/5/20.) (Patent of Addition not granted.)
173 316 BRITISH THOMSON-HOUSTON CO., LTD., and WEDMORE, E. B. Protective devices for alternating current electric distribution systems. (28/9/20.)
173 317 WALL, T. F. Alternating current generators. (28/9/20.) (Cognate application, 6 205/21.)
173 320 BRITISH INSULATED AND HELSEY CABLES, LTD., BAYLES, E. A., and HIGHAM, H. Electrical condensers. (29/9/20.)
173 329 BOOTH, A. C., and WILLMOT, A. S. Telegraph keyboard perforators. (30/9/20.)
156 096 COOLIDGE, W. D. X-ray apparatus and methods. (9/7/20.)
173 363 GENERAL ELECTRIC CO., LTD., and TRIPPE, C. F. Vacuum or low-pressure bulb electron-discharge apparatus. (16/10/20.)
173 368 BOOTH, A. C., and WILLMOT, A. S. Mechanism for providing feed-holes to the paper-tape of telegraph perforating instruments. (20/10/20.)
158 224 GRAF, A. Switches for electric installations. (26/1/20.) (Patent of Addition not granted.)
173 402 RAPHAEL, F. C., and EDISON SWAN ELECTRIC CO., LTD. Means for bonding metal-covered electric cables and wires. (22/11/20.)
173 404 TIMMINS, R. Electric fuse contact embodying a method of holding or clamping fuse wire. (24/11/20.)
155 819 PLATSCHICK, B. Mounting of brush-holders upon electric motors. (24/12/19.)
173 413 IGRANIC ELECTRIC CO., LTD. (Cutler-Hammer Manufacturing Co.). Electric motor controllers. (30/11/20.)
154 906 BOSCH AKT.-GES., R. Magneto-electric ignition machines. (3/12/19.)
173 419 DAVIS, W. J. Electrical connectors. (13/12/20.)
173 442 COOK, J. W. Portable accumulators. (3/2/21.)
173 450 OLIVER, A. L. Electric blasting-fuses. (7/3/21.)
168 583 WESTINGHOUSE BRAKE AND SAXBY SIGNAL CO., LTD. Control of electrically-operated fluid-compressors. (31/8/20.)
164 756 SIEMENS-SCHUCKERTWERKE GES. Air-removing apparatus adapted for use with mercury vapour rectifiers and like devices operating with a permanent high vacuum. (15/6/20.)
173 531 ANGUS, A. R. Electric control of railway trains or vehicles. (10/7/20.)
173 535 MEI, P. Sparking-plugs for internal-combustion engines. (25/6/20.)
146 175 SIEMENS-SCHUCKERTWERKE GES. Asynchronous electric motors. (30/3/16.)
146 176 SIEMENS-SCHUCKERTWERKE GES. Asynchronous electric motors. (12/1/17.) (Addition to 146 175.)
146 242 SIEMENS-SCHUCKERTWERKE GES. Asynchronous electric motors. (30/3/16.)
173 530 MICHIGAN SPARK PLUG CO. Electric ignition plugs. (31/1/19.)
147 037 SCHRÖTER, F. Electric-discharge apparatus. (23/1/18.)
148 132 BRITISH THOMSON-HOUSTON CO., LTD. Electron-discharge apparatus. (28/10/15.)
148 322 HUTH GES., DR. E. F. and LOEWE, DR. S. Method of tuning direct-coupled transmitting-apparatus for wireless telegraphy. (18/9/15.)
173 549 SATTERTHWAITE, A. Automatic switch which is particularly suitable for electric hoists. (20/7/20.)
173 556 BRITISH THOMSON-HOUSTON CO., LTD. (General Electric Co.). Induction motors. (5/8/20.)
150 352 LEVY, L. Anti-parasitic selecting and receiving system for telegraphy and telephony with or without wires. (25/8/19.) (Addition to 133 306.)
173 568 TAGGART, J. SCOTT-, and FARLEY, G. G. Construction of thermionic valves as used in wireless signalling systems. (3/9/20.)
151 611 HOLST, DR. G., OOSTERHUIS, DR. E., and NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABREKEN. Process for removing gas residues and for purifying inert gases in electric vacuum tubes, incandescent lamps, and the like. (23/9/19.)
173 606 BRITISH THOMSON-HOUSTON CO., LTD. (General Electric Co.). Electric inductance apparatus. (4/10/20.)
173 613 WATKINSON, J. Resistance switches for controlling the intensity of electric currents. (5/10/20.) (Cognate Application, 21/12/21.)
173 621 CREED, F. G., and CREED AND CO., LTD. Circuit-controlling apparatus suitable for use in wireless telegraphy. (8/10/20.)
173 629 MIDGLEY, A. H., and VANDERVELL AND CO., LTD., C. A. Electric-starters for internal combustion engines. (14/10/20.)
173 633 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD., WEBSTER, P., and MERCER, R. Telephone systems. (18/10/20.)
173 638 SHANNON, W. H. Portable electric lamps. (19/10/20.)
173 641 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD., and SAVIN, J. Telephone systems. (21/10/20.)
155 568 AUTOMATIC TELEPHONE MANUFACTURING CO., LTD. Measured service telephone systems. (13/12/19.)
173 643 WATSON, E. A., and M-L MAGNETO SYNDICATE, LTD. Distributors for high-tension ignition apparatus. 21/10/20.)
173 648 MCKENZIE, HOLLAND, AND WESTINGHOUSE POWER SIGNAL CO., LTD., and PEARCE, W. A. Electric relays. (25/10/20.)
173 649 ROBINSON, H. Magnetic circuit of electrical motors and dynamos. (25/10/20.)
173 657 IGRANIC ELECTRIC CO., LTD. (Cutler-Hammer Manufacturing Co.). Thermally-controlled circuit interrupters. (2/11/20.)
173 660 CHESHIRE, H., and SUMMERHAYES, V. Electrical heating units. (11/4/20.)
173 661 BARKER, A. J. Self-acting locking lamp-holder for incandescent electric lamps when same are inserted. (4/11/20.)
173 669 DANSON, R. J. Trolley heads for electrically propelled vehicles. (12/11/20.)
173 671 OLDHAM, O., OLDHAM, G., and OLDHAM, J. Galvanic batteries. (15/11/20.)
173 674 THORNTON, A. A. (Ignition Co. of America). Spark-plug. (22/11/20.)
154 936 OESTERREICHISCHE SIEMENS-SCHUCKERTWERKE. Method of controlling continuous current motors. (29/1/16.) (Divided Application on 145 589.) (Addition to 145 589.)
157 331 STALHANE, O., and KRING, O. O. Electric connecting plugs. (27/11/18.)
168 600 BOUDOU, G. Electric apparatus for the permanent waving of the hair. (26/3/20.) (Divided Application on 160 746.)
146 294 QUICK ACTION IGNITION CO. Magneto-electric generators. (17/2/16.)
173 793 LATOUR, M. Thermionic-tube amplifying devices. (7/7/20.)
147 760 LATOUR, M. Multiplex telegraph and telephone systems. (25/6/15.)
147 855 REICHENHEIM, DR. O. Wireless telegraph receivers. (10/9/15.)
147 856 KOSSEL, W. Electric discharge tubes. (23/12/16.)
147 882 SIEMENS-SCHUCKERTWERKE GES. Dynamo-electric machines. (15/6/18.)
148 184 KOSSEL, W. Electric discharge tubes. (1/3/17.)
148 525 GES. FÜR DRÄHTLOSE TELEGRAPHIE. Production of oscillations by high vacuum tubes having heated cathodes. (30/4/19.)
148 971 GES. FÜR ELEKTROMECHANISCHE TELEPHONAPPARATE. Circuit arrangements of automatic telephone exchanges. (10/1/14.)
148 891 GES. FÜR DRÄHTLOSE TELEGRAPHIE. Generator of electric oscillations consisting of a thermionic tube in return coupling connection. (7/8/17.)
149 213 HUTH GES., DR. E. F., and LOEWE, DR. S. Thermionic valve amplifiers and generators. (4/7/17.)
149 218 LOEWE, S. Thermionic receiving apparatus for wireless signalling. (18/4/18.)
149 663 EBNER, A. Electrically-driven talking-machine. (12/7/20.) (Convention date not granted.)
173 800 BRITISH ELECTRIC TRANSFORMER CO., LTD., and ROOTHAAN, J. Electric transformers. 14/7/20.)
173 807 ALEXANDER, A. E. (Newsprinter Corporation). Printing-telegraph receivers. (9/8/20.)
173 812 WILD, L. W., and BARFIELD, E. P. Electric furnaces. (11/8/20.)
150 961 GOUIN, P., and ROESEL, E. Alkaline storage batteries. (10/9/19.)
173 832 BRYDON, S., and JOHNSON, S. Wireless telegraphy. (13/9/20.)
151 935 BOSCH AKT.-GES. R. Means for securing machines such as dynamo-electric lighting-machines for cycles and the like. (2/10/19.)
158 865 RAMONEDA, C. Manufacture of frames for polyphase dynamo-electric machinery. (10/2/20.)
151 999 BRITISH THOMSON-HOUSTON CO., LTD. X-ray apparatus. (29/10/13.)
173 848 FREI, F. Electric immersion heaters. (5/10/20.)
152 032 MAAG, F. Eleceric heating-devices. (8/10/19.)
173 859 BRITISH THOMSON-HOUSTON CO., LTD. (General Electric Co.). Electric welding apparatus. (7/10/20.)
173 865 VENTIHETA (UNITED KINGDOM), LTD., and OGLE, P. J. Electric heating and ventilating apparatus. (8/10/20.)
173 868 RICHARD, A. Insulators for the suspension of high-potential electric lines. (8/10/20.)
173 869 AARONS, S. E., and SMITH, A. P. Hand-tools for electricians and the like. (8/10/20.)
173 873 SIMPSON, J. Electrical indicating-apparatus for indicating the opening or closing of electrical contacts and the sequence in which the contacts were opened or closed. (9/10/20.)
152 683 CORDES, H. G. Radio interference preventers. (21/10/19.)

APPLICATIONS FOR PATENTS.

June 6, 1922.

15 633 C. A. COLEMAN. Automatically lighting electric street lamps.
15 636 R. SIMPSON. Magnetos.
15 681 F. B. COX. Automatic electric switches.
15 690 J. R. LAIRD and G. PATE. Insulated cable.
15 709 A. REYROLLE AND CO., B. H. LEESON and W. D. OWEN. Alternating current transformers.
15 710 D. H. BRAYNE. Selective switches for electric inductances, etc.
15 730 J. A. SLEE. Primary batteries.
15 737 M. J. RAILING and C. W. SAUNDERS. Electric camp fittings.
15 744 H. D. NYBERG. Galvanic cells.
15 749 INTERNATIONAL ELECTRIC Co. and F. R. BALDOCK. Central battery exchange telephone systems and switchboards.
15 750 H. BARON (Aldendorff). Electric switching apparatus.
15 751 B. T.-H. Co. and A. S. FITZGERALD. Electro-responsive devices.
15 765 G. W. HUMPHRY. Insulating and protecting wires or cables.
15 767 SKYWING AIRCRAFT CORPORATION. Electric ignition devices. (1/12/20, U.S.)

June 7, 1922.

15 808 W. H. SMITH. Instrument for distributing audibility of wireless speech, etc.
15 817 J. B. BIGNAMY and H. R. HEWLING. Wireless tuning inductances.
15 830 B. T.-H. Co. and R. D. GIVEN. Controllers for electric circuits.
15 845 WESTERN ELECTRIC Co. Telephone systems. (16/6/21, U.S.)
15 852 ALLGEMEINE ELEKTRICITATS GESELLSCHAFT. Apparatus for driving talking machines. (25/6/21, Germany.)
15 857 STERLING TELEPHONE AND ELECTRIC Co. and F. CLARK. Telephone receivers.

The J & P Pages

A unique booklet designed for — Your own distribution

To any Contr ctor who is anxious to make the most of the present demand for wiring work it will be—well, more than helpful.

It is propaganda which impels enquiry, and when you have the enquiry it is "half the battle"—more than half if you estimate on the basis of the J & P System—the system that's "so simple" and so markedly economical.

Remember, you can assure your customers that you can do the job, and leave them entirely free from redecoration bills!

The booklet is attractively produced, unique in character and style, carries no name but yours (which is printed on an enquiry P.C. lipped into the front cover), and, in addition, is supplied with envelope. Are you interested? Are you open to "make a push" with the "J & P"? If so—this is how we help you.

Write us and arrange for a supply.

5,000 kW 3,000 r.p.m. Brush-Ljungström Turbo-Generator.
(1227)

TURBO-GENERATORS

The economy of operation and reliability of the "Brush-Ljungström" Turbo-Generator is a proved and well established fact.

We have built upwards of 200,000 kW of these units, which are giving every satisfaction in Power Stations both at Home and Abroad.

WE CAN GUARANTEE TO OBTAIN A LOWER STEAM CONSUMPTION THAN CAN BE OBTAINED BY ANY OTHER PRIME MOVER.

TRANSFORMERS

Since commencing the manufacture of Transformers twenty-seven years ago, our yearly output has shown a steady increase.

We specialise in the production of Transformers for all classes of duty ; both indoor and outdoor.

Our Transformers are designed to withstand the heavy service conditions of operation in close proximity to large generating units. Excellent workmanship, combined with the use of the best possible materials throughout, have secured a reputation for Brush Transformers which is second to none.

CAMBRIDGE STATOR AND ROTOR TEMPERATURE OUTFITS

STATOR TEMPERATURE INDICATORS

THE Outfit for Stator Temperatures consists of a double pivoted indicator of high sensitivity enclosed in a dust-proof case with a multi-way switch, together with fine gauge flexible thermo-couples which are embedded in the stator windings. The cold junction of the thermo-couples is controlled by a thermostat, buried junction or vacuum flask.

ROTOR TEMPERATURE INDICATORS

IN Rotor Temperature Outfits the changes in the resistance of the rotor are measured by a differential ohmmeter which is calibrated in terms of temperature.

This ohmmeter is similar in external appearance to the Stator Indicator.

THESE instruments are included as standard equipment by most of the leading turbine builders. When you are putting down your turbine plant

specify "Cambridge Instruments."

TENDERS INVITED.

LONDON COUNTY COUNCIL.

TENDERS are invited for the supply, delivery and erection of HIGH TENSION SWITCHGEAR at the CENTRAL REPAIR DEPOT, CHARLTON. The specification, form of tender and general conditions may be obtained from the Clerk of the Council, County Hall, Westminster Bridge, S.E.1, on payment to the Cashier of the Council of a deposit of £2, which amount will be returnable on receipt of a bona fide tender. Particulars of the work may be obtained on application at the County Hall before payment of the fee.

Tenders should be addressed to the Clerk of the Council and delivered at the County Hall, Westminster Bridge, S.E.1, not later than four p.m. on Monday, July 24, 1922. No tender received after that time will be considered.

The Council does not bind itself to accept the lowest or any tender.

JAMES BIRD,
Clerk of the London County Council.

WIRE TINNED COPPER. Schedule 31, August 15. CABLE SWITCHBOARD SILK AND COTTON COVERED. Schedule 35, August 22. AUTOMATIC COMMON BATTERY TELEPHONE EQUIPMENT, TOGETHER WITH ALL ASSOCIATED EQUIPMENT, INCLUDING EQUIPMENT FOR USE AT SUBSCRIBERS' PREMISES. Schedule 39 and 40, October 17. PROTECTOR APPARATUS. Schedule 563, August 9.

Tenders, returnable on the dates named, are invited by the Commonwealth of Australia for supply of the above-mentioned. For Tender Forms, Specifications, and full particulars apply, SUPPLY OFFICER, Room 101. Australia House, Strand, London.

TELEGRAPH AND/OR TELEPHONE APPARATUS, TESTING INSTRUMENTS, PROTECTIVE APPARATUS (Schedule 734). Tenders are receivable for the above by the Deputy Postmaster-General, Perth, Western Australia, up to noon on Wednesday, 26th July, 1922. For Tender Forms, Specifications, etc., apply SUPPLY OFFICER, Room 101, Australia House, Strand, London, W.C.2.

THE High Commissioner for India is prepared to receive TENDERS for the supply of :—

1. Automatic Telephone Sets, Desk and Wall.
2. Cords for Telephone Switchboards, etc.
3. Cells of various descriptions for Accumulators.

Forms of Tender may be obtained from the Director-General, India Store Department, Belvedere Road, Lambeth, S.E.1, and Tenders are to be delivered at that Office not later than TWO o'clock p.m. on Friday, July 21, 1922.

T. RYAN,
Director-General.

PATENT RIGHTS FOR SALE, &c.

THE Patentee of certain "Improvements in apparatus for transforming, and especially for rectifying, alternating or polyphase currents," No. 102 977, already in successful operation on the Continent, desires to procure the commercial working of the invention in the United Kingdom, and with that object is prepared to grant licences to suitable British Manufacturers and to furnish them with all necessary information and assistance. Enquiries may be addressed to Mr. G. G. M. HARDINGHAM, Clun House, Surrey Street, London, W.C.2.

PATENTS AND DESIGNS ACTS, 1907 AND 1919.
"ELECTRIC ROTARY CONVERTERS."

THE Proprietors of British Letters Patent No. 16933/15 are prepared to sell the patent or to license British Manufacturers to work under it. It relates to a rotary converter having an automatic switch controlled by the speed of the armature to open and close the outgoing alternating current circuit.

Address: B. W. & T.,

ON SALE, Two Electric Automatic Type-Printing Ticker Equipments, transferred from Buenos Aires and Rio de Janeiro after short working, say 3 to 400 Tickers with Motors, Dynamos and Accessories, in impaired condition.—Full details and specifications provided on application to COMTELBURO, LIMITED, 11, Tokenhouse Yard, E.C.2.

TELEPHONES, National desk portable, Magneto ringing, complete with battery case, flex, and terminals, 25s. each. Exchanges 8 lines. 30s. each.—D. GREEN AND SON, Seymour Road, Lytham, Lancs.

FOR SALE.—Offices without a copy of the "Electrician" Electrical Trades' Directory for 1922 are without the only publication that contains a complete Trades' Directory of the Electrical Industry. 1,450 pages, 50,000 entries. Price 25s. net. Postage (Inland) 1s.—BENN BROTHERS, LTD., 8, Bouverie Street, London, E.C.4.

FOR SALE.—Particulars and Valuable Statistics relating over 1,750 British Colonial and Foreign Electricity Supply Undertakings are given in the 1922 Edition of the "Electrician" Tables. Bound in limp cloth, price 10s. net, by post 10s. 9d.—BENN BROTHERS, LTD., 8, Bouverie Street, London, E.C.4.

PARTNERSHIP WANTED.

DIRECTORSHIP.—Mr. J. F. Poynter, 75, Canonbury-Road, N.1, will be glad to hear from friends willing to associate with him in the reconstruction and future management of the "Maxim" lamp factory. £5 000 required.

EDUCATIONAL NOTICE.

FINSBURY TECHNICAL COLLEGE,
LEONARD STREET, CITY ROAD, E.C.2.

DEAN FOR THE SESSION, 1921-22:
PROFESSOR W. H. ECCLES, D.Sc., F.R.S.

The College provides practical scientific training for Students who desire to become Civil, Mechanical, or Electrical Engineers, or Chemists.

Candidates are required to pass an Entrance Examination in Mathematics and English, but the Matriculation Certificate of any British University, and certain other qualifications are accepted in lieu of it. The next Entrance Examination will be held on Tuesday, September 19. Applications for admission should be forwarded to the College on forms to be obtained from the REGISTRAR. The Programme of the College is under revision and will be issued shortly.

SITUATIONS VACANT.

BELFAST CORPORATION.

ELECTRICITY DEPARTMENT.

APPLICATIONS are invited for the position of GENERATING ENGINEER. Candidates must have had experience in a large power station and be conversant with e.h.t. three-phase generation from coal to switchboard. He will be responsible to Works Superintendent for the efficient operation of the plant and will have control of station operation staff.

Salary in accordance with N.J.B. Schedule, Class F, Grade 5.

Applications, stating age, giving full particulars of training, experience, qualifications, and the earliest date on which duties could be commenced, together with copies of three recent testimonials, to be received not later than Monday, July 10.

JOHNSTONE WRIGHT, M.I.E.E.,
City Electrical Engineer and Business Manager.

Electricity Works,
East Bridge Street, Belfast.
June 27, 1922.

MAN used to Wireless to take charge of Department in the Midlands, handling popular sets for "Broadcasting" reception. Must thoroughly understand technical and commercial details, able to buy in right markets and prepare Sales Campaigns. Part salary and payment by results.—Apply, stating experience and enclosing copy references to J. X. G., ELECTRICIAN Offices, 8, Bouverie Street, E.C.4.

THE Advertisers under Box J.W.Z. beg to thank applicants and to say the position is now filled.

SITUATIONS WANTED.

JUNIOR ELECTRICAL DRAUGHTSMAN, age 21, wishing to gain experience, seeks post with Municipal Undertaking or Manufacturer. H.T. and L.T., Switchgear, Substations, Mains, Lighting.—BOX J. X. E., ELECTRICIAN Offices, 8, Bouverie Street, London, E.C.4.

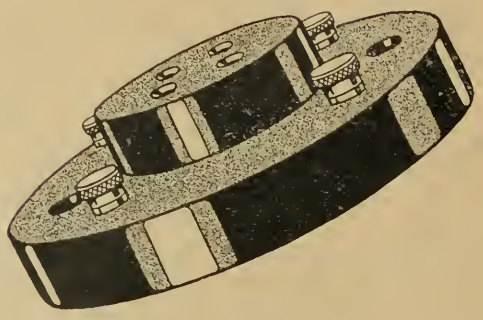
WIRELESS.—Public School man, first-class certificate Marconi, Telefunken systems, nine years' experience spark, valves, telephony, requires appointment. Late Wireless Officer R.A.F. Thoroughly acquainted modern practice and latest developments amateur work; good knowledge general electrical work; highest references; moderate salary.—Box J. X. C., ELECTRICIAN Offices, 8, Bouverie Street, E.C.4.

MISCELLANEOUS.

WANTED.—Electrical Contractors in good residential districts to handle the "Briarton" (British) Electric Washing Machine. Good discount and technical assistance free.—Particulars from ARTON AND WALTON, LTD., sole makers, Thomas Street, Chetham Hill, Manchester.

OUR BOOK DEPARTMENT can supply your needs in TECHNICAL BOOKS and places its services at your disposal. Send full information of your requirements to MANAGER, Book Department, BENN BROS., LTD., 8, Bouverie Street, London, E.C.4.

MULLARD VALVE EQUIPMENT



TO ensure that users of MULLARD VALVES shall obtain the best results from them, we recommend that they should be used in conjunction with MULLARD VALVE EQUIPMENT.

MULLARD RESISTANCES Patent No. 131.057/19.

For use in the grid or anode circuit are constant in value, have a long life and are practically independent of climatic conditions.

Prices . . .

Grid A., 7/6 ; Anode A. and B., 8/- each.

MULLARD CONDENSERS—

Are a very convenient form of cylindrical condenser, for use either in grid or anode circuit.

Price . . .

Type C.A. .0002 - - .004 Mfd. 10/- each

CONTENTS.

Notes of the Week.

The First Electricity District Authorised.

THE second inquiry into the scheme for the South East Lancashire Electricity District proved to be formal, only occupying a couple of hours. The brevity and comparatively harmonious character of the proceedings are to be attributed to the fact that the engineers, led by Mr. S. L. PEARCE, had agreed upon a policy which, while it confers the local autonomy desired in the district, gives useful powers of co-ordination of both supply and expenditure. The new Advisory Board will not have much to do or say except to advise and recommend, but in the course of time, as the good effects of co-operation manifest themselves, we have no doubt its influence will grow, and it may lead to a closer association of the various supply authorities —even to the formation of a Joint Electricity Authority.

Railway Companies' Frivolous Opposition.

THE only objection to the formation of the Advisory Board came from the railway companies serving the district, though we cannot see any substance in their demands. The Midland Company objected to the compulsory supply of statistics, but as all railways are so accustomed to the preparation and supply of statistics there can be no real grievance in having to supply a few extra figures relating to the generation and use of electricity. The opposition of the North Western Company was to the Commissioners having the right to accept any recommendation of the Advisory Board. This sounds somewhat like objecting to the principles of the Electricity (Supply) Act of 1919 and to the powers of the Commissioners, and will, we hope, receive speedy justice. The Town Clerk of Manchester asked for the insertion of clauses authorising the payment of pensions to retiring officials and to enable members of the new Board to be paid for loss of remunerative time while engaged on the affairs of the Board. As practically the whole of the useful work to be done will be performed by the Committee of Engineers, we hope that the Commissioners will consider this matter very carefully and will hesitate to set up what may be a dangerous precedent for using public funds in an improper way.

Substation Practice and Performance.

IT is unfortunate that circumstances, avoidable and unavoidable, combined to cut short the discussion on Mr. R. A. CHATTOCK's Paper at the I.M.E.A. Convention last week. For when it withered in its early prime it showed every prospect of becoming a valuable contribution to those eternal problems: the comparative advantages of alternating and direct current for distribution purposes and the economic value of providing sufficient plant to keep the supply going in every conceivable circumstance. Short as the discussion was it showed, however, that the consensus of opinion is against Mr. CHATTOCK on the second of these two points. He, it will be remembered, preaches and practices direct current distribution combined with every precaution to ensure continuity of supply in the strictest interpretation of the term. The natural corollary is, therefore, not only an unusual proportion of spare converting plant in the substations, but a battery capable of maintaining the supply for two hours.

Some Disadvantages of the Substation Battery.

NOW a battery is at best an inefficient piece of apparatus for such a purpose. It is costly in itself, £35 per kW is the figure mentioned in the Paper, and it adds to the costs of the land, buildings, and switchgear involved in the

substation construction. If it is to be used entirely in emergency it is a form of over-insurance which cannot be recommended, and, if it is to be employed as a part of the ordinary substation plant, its work can be better done in other ways. It is significant to note that though Mr. CHATTOCK has been using batteries in substations for some years, and that though in 1914 his policy was commended it has never been widely followed; and is now almost universally condemned.

Moving Towards A.C. Distribution.

THIS condemnation is due to a greater cause than any defect inherent in the battery itself: the accelerated movement towards alternating current distribution, combined with a desire to get away from complications and approach simplicity in power station practice. The lot of the supply engineer saddled with a direct current system is therefore not a happy one, though he is offered methods of overcoming his difficulties which are worth examination. In making a choice it will be necessary for economic reasons to take risks rather than to play for safety. As was emphasised by many speakers not only during this discussion, but throughout the meeting, it is useless to talk about "cheap and abundant" electricity if the engineering policy of our supply undertakings mainly results in increased capital costs. For this and for other reasons it is a thousand pities that the discussion was so curtailed. We hope an early opportunity will be taken to deal further with the subject.

Municipal Finance.

THE Paper read by Mr. EDWARD CALVERT before the Incorporated Municipal Electrical Association last week raises an important question: How far shall the finance of a municipal electricity department be controlled by an official who is not under the orders of the head of that department? This is one of those questions which it is meet that a body like the I.M.E.A. should consider, but it is one to which it is difficult to give a general answer. This was evidently realised by those who discussed the subject, many of whom inclined to consider that both the problem and its solution lay in the clash of the personalities of those most concerned—the electrical engineer and the borough treasurer. In other words that it would be best to arrange for the quality of tact to be present in full measure in the composition of those two officials, and to trust to it rather than to written laws and regulations.

A Financial Responsibility Necessary.

BUT further consideration will show that the matter cannot be left there. It is obvious on the one hand that nothing is to be gained by the electrical engineer insisting on dealing with such matters as the raising of loans or similar pure financial questions. On the other hand everything is to be gained by the electrical engineer having full financial control of his own department; in fact disaster will follow if he does not have that control. Fortunately for the success of municipal electricity supply the large majority of cases fall between these two extremes and can be dealt with by a "give and take" policy such as that outlined by Mr. W. C. P. TAPPER. In cases where the collection of accounts has been allowed to fall into the hands of the borough treasurer it is rather a matter for the conscience stricken engineer to deal with than to bring into play the full weight of the Association. In any event, as Mr. WORDINGHAM said, the engineer must have many tools in his bag, and a knowledge of finance is one that should be kept among the sharpest and most constantly in use.

Expenses—Wholesale or Retail.

BY far the liveliest discussion at the I.M.E.A. Convention was on whether the expenses of members attending Council and Committee meetings should be paid by the Association or by the authorities employing the individuals concerned. The latter is the present procedure and the weight of opinion seems to be in favour of its continuance. But so divergent were the views expressed and so hot some of the threats of what would follow if this or that policy were or were not adopted that the meeting took the wisest, if not the most heroic, course in postponing further consideration until next year. We hope that even after further consideration no change will be made. Individual local authorities gain advantages from having a member on the Council and in the large majority of cases have no objection to paying for these increased facilities. On the other hand it is obvious that if each local authority pays a share, on whatever basis that share is arranged, the way will be open to undesirable bickering.

A Chance for Logical Action.

ANOTHER reason for making no change is that it is just as well, even for associations, to be logical when they can. To pay the Council members' expenses on a communal basis and then to object to paying the Commissioners' expenses on the same basis would hardly do. Yet we note that the Association passed a strongly worded resolution that the Commissioners' expenses should be a national charge, which is going a step or so farther. On its merits there is much to be said for making the change. A large undertaking may cause the Commissioners very little trouble (or expense), and contrariwise a small undertaking may cause them both, yet on the unit basis one will pay a great deal more than the other. Moreover, as the work of the Commissioners is undertaken for the good of the nation as a whole, it might well be argued that it should be paid for by the nation and not only by a section of it. We are glad, therefore, that the resolution was carried in spite of a characteristic outburst from Mr. PURSE, who drew a lurid picture of the results of Government control. This, however, is largely a bogey. The Commissioners work under statutory authority, and wherever their money comes from will continue to perform their duties in an atmosphere as free as possible from Treasury minutes. A more weighty reason for the change is that these expenses are becoming a heavy charge on many undertakings with the unfortunate result that "cheap and abundant" electricity is being relegated to an ever and ever more distant future.

Possibilities of Tramway Development.

THE papers read at the 14th annual congress of the Tramways and Light Railways Association last week revealed an undercurrent of dissatisfaction with progress and a suspicion, most frankly expressed by Mr. SPENCER, that tramway undertakings will have to rouse themselves if they are going to compete successfully with other forms of motor traffic. The record of the Bournemouth tramways narrated by Mr. BULFIN was not a very inspiring one. He explained past difficulties by the fact that the Bournemouth Corporation was not born with tramways, hardly achieved them, but rather had tramways

thrust upon them! It was many years before the differences between the various interests were composed. Even to-day Bournemouth, as a seaside resort, is not an ideal place for a tramway undertaking. The winter months almost inevitably lead to loss, which may or may not be recouped by the influx of visitors during the summer.

Railless Traction.

Mr. Munro, in dealing with railless traction, made out a good case for this system in circumstances where the cost of construction of a permanent track is not warranted; possibly Bournemouth might have benefited from the method, had it been available in the past. The great advantages are doubtless the low capital charges and small cost per passenger mile. The author, however, did not make enough of another advantage over the tramway—the greater elasticity arising from the fact that cars are not tied to a line of rails, and so have more freedom in negotiating traffic and avoiding blocks due to the breakdown of an individual car.

Improvements in Rolling Stock.

The third paper, by Mr. Spencer, dealt with improvements in rolling stock. The contrast between the title and contents of the paper reminds one of the famous chapter on "Snakes in Iceland." There aren't any. It is doubtless broadly true, as the author contends, that rolling stock is substantially similar to that used 20 or 25 years ago. The improvements he suggests, largely with a view to diminishing weight, noise, and vibration, would doubtless be valuable, though hardly revolutionary. There is, however, good ground for thinking that tramcars constitute a peculiarly good example of the British passion for solidity, and that their weight might, with advantage, be materially reduced. Mr. Spencer does no more than justice to the enterprise of designers of motor vehicles. But it must be conceded that in a vehicle that proceeds along iron rails and is essentially electrical, the line of development was, from the first, much more clearly defined.

Electricity Supply in Manchester.

The results of the past year's working of the Manchester Corporation electricity department, the largest and most important municipal undertaking in the United Kingdom, are not quite as good as those for 1920–21. Considering the circumstances, however, they are quite as satisfactory as could be expected. The total revenue was nearly £1 430 000, compared with £1 547 226, a decrease of over £117 231, mainly due to a drop in the sales of current for lighting and power. The working expenditure was £138 137 less, so that the gross profit was £452 893, against £431 987 in the previous year; but as interest, sinking fund and other payments absorbed £408 329, the net surplus was only £44 564, against £69 123. All interest and sinking fund charges for the year on the new Barton power station and the high tension mains therefrom were met out of revenue, and to this fact, coupled with the restrictions on the use of electricity, and the increased cost of coal, must be attributed the temporary setback, for we feel sure it is not more than temporary. The total sales decreased by 21 per cent. (158·5 million units against 199 618 813), a strange experience for a department which has shown progressive increases every year since its inauguration, except in 1919 and 1920. The average price of fuel only fell by 1s. 4d. a ton, and the average weight of fuel rose 0·03d. per unit sold, but we imagine there will be a substantial improvement on these figures during the current year as the quality of the coal has improved and its price has decreased.

Year's Progress and Developments.

We are interested to note that fair progress has been made with the Barton power station, though it is to be feared there will be a delay in the erection of the plant owing to the engineers' strike. No. 1 boiler house at Stuart Street has been modernised, and an additional 8 000 kW turbo-alternator and condensing plant have been installed. This station now contains 100 250 kW of plant, and it is therefore probably the largest single station now operating in the country, at any rate municipally owned. A number of sub-stations, both d.c. and a.c., have been enlarged or erected; a net addition of over 50 miles has been made to the mains, and considerable progress has been made with the 33 000 V transmission cables in connection with the Barton supply. The electric lighting of six streets was carried out, thus completing the scheme of public lighting sanctioned by the Council. There are now 858 public electric lamps, compared with 564 in 1921. A considerable advance has also been made with the lighting of the various housing estates, and work has been completed on the inhabited portions of six estates. It will thus be seen that the past year was one of great activity and progressive achievement in many ways. The total capital outlay is now £5 607 698, but the mortgage debt is only £3 248 936, and there are substantial reserve and renewals accounts, amounting jointly to nearly £230 000. The undertaking is therefore in a prosperous condition, and provided the trade boom materialises, next year's accounts should show a decided improvement.

Railway Accident Statistics.

The "Returns of Railway Accidents during 1921" and the report of the Ministry of Transport Committee, presided over by Colonel Pringle, which was appointed in October 1920 to consider the adoption of automatic train control, have been issued with an opportune simultaneity. With regard to the former, out of 1 217 687 000 passengers carried only 18 were killed in accidents to trains and 71 from other accidents connected with the running of trains or other railway vehicles. In addition 11 railway servants and three other persons were killed in accidents, while suicide accounted for 250, making a grand total of 726 for passengers and railway servants killed for one reason or another. This figure is very small compared with the number of passengers carried, and except for the suicides, with whom it is difficult to know how to deal, it might be argued that perfection has as nearly been reached as it ever will be.

The Advantages of Automatic Control.

But the object of automatic train control is something other than the prevention of accidents, useful as that prevention will be. In the first place it will make possible the acceleration of both signal and train movements, and for these reasons its use is almost compulsory where electrification is undertaken. It will relieve a number of men from an exacting and heavy task, and, while increasing efficiency, will at least reduce a number of unnecessary deaths due to human or mechanical failure. Experience on the London Underground Railways is sufficient guarantee of that. It is interesting to note that after a

period of prejudice the drivers are now favourably inclined to train control, and the real difficulties are to make a selection of the various systems and to take the necessary steps towards the standardisation of both track and locomotive equipment. With this end in view the Committee, who see the weak points rather than the advantages in all the systems now available, recommend the immediate formation of a committee of experts for this purpose. From the merely human point of view it is work that should be undertaken.

The Northumberland Clause in a Gas Bill.

THE principle embodied in what is known as the Northumberland clause, has in the past been applied to a number of electricity undertakings. It is somewhat of a novelty, however, to see it in a gas Bill. As our readers know, it was introduced in 1904 at the instance of the gas interests who dreaded the effect of competition by municipal electricity undertakings. Generally speaking, the clause which imposes upon municipal authorities the obligation of fixing their charges for electricity supply so that their undertakings shall not become a charge upon the rates, is fair, for all municipal services such as electricity or gas should be self-supporting. Therefore we are glad a Select Committee of the House of Commons has now inserted the clause in the Bill of the Stretford Joint Gas Board, which is to take over the business of the old gas company. The Board will not be allowed to impose a rate-in-aid until the maximum permissible price has been reached, and when this event happens it must apply to the Board of Trade for authority. Thus a device invented for the protection of gas interests is now being applied against them! Poetic justice!

The Eastern Companies Jubilee.

WHEN an industry celebrates its jubilees, as the electrical industry is now doing, it is not necessarily a sign that it is growing old. Indeed we are pleased to think that in the case of our own industry it is an indication of an increased virility and of a determination to make progress in the future proportional to what has been made in the past. That, we feel sure, is the view of those responsible for the conduct of the Eastern and Associated Telegraph Companies, a group of undertakings which will celebrate their jubilee on July 24 by a banquet, fete and reception in the gardens of the Royal Botanic Society. The DUKE OF YORK has expressed his intention of being present, and invitations have been issued to men and women, both British and foreign, who are distinguished in science, art, and literature. The opportunity is to be seized by the staffs of the companies to present their chairman, Sir JOHN DENISON-PENDER, with a volume containing the signatures of nearly 8 000 subscribers, and the reproduction in platinum set with brilliants of the stars of the Orders of St. Michael and St. George, and of the British Empire. In addition, a bed will be endowed in St. Bartholomew's Hospital in memory of the late Lady DENISON-PENDER.

Fifty Years of Progress.

IN our Diamond Jubilee issue last November we gave a detailed account of the progress with which the Eastern Telegraph group had been connected. It will be sufficient to say here that when the Eastern Co. was incorporated in 1872, only about 8 000 nautical miles of cables were in existence, while now there are roundly 325 000 miles. The capital invested in submarine cable enterprise fifty years ago was £2 000 000, now it is £50 000 000, nearly half of which is represented by the undertakings comprising the Eastern and Associated Telegraph Companies. Technically, though not so spectacular, progress has been equally sure. And it is interesting to note that the Eastern Co., by establishing their own research department were among the first to realise that for success science, technology and commerce must go ever hand-in-hand. They have built firm and sure. There is little doubt that the next fifty years will add further success to their credit, so that the celebration will not only recall the past, but welcome the future.

A Duty on Illuminating Ware.

THE Report of Sir WILLIAM ASHLEY'S Committee on Domestic, Illuminating and Mounting Glassware, is of some interest to readers of THE ELECTRICIAN as, in consequence of its findings, an Order has been made by the Board of Trade imposing a duty of 33⅓ per cent. on glass imported from Germany. The Committee found that the import of electric bulbs in 1921 from Germany and Czecho-Slovakia was not on a sufficiently large scale to have a serious effect upon unemployment. On the other hand, the Committee find (with one dissentient) that the statutory conditions, required before a duty can be imposed on domestic and illuminating ware, were fulfilled. Consequently, an Order has been made applying the duty for two years. This is good; but we regret the restriction should be confined to German goods alone, for we are afraid that under the circumstances neither the manufacturers nor the workers in the British glass industry will reap much benefit.

The Newcomen Society.

At the second summer meeting of the Newcomen Society, which was held recently in London, the proceedings were mainly devoted to visits to places of either intrinsic historical interest or where equipment of historical interest was to be found. The first of these included Westminster Hall, with its centuries-old roof, and a great deal of time was spent in inspecting the steps that have been taken to repair and protect the roof of this structure from the ravages of the death-watch beetle. In the second class were the Rotunda at Woolwich, where old arms and ordnance were examined, the Naval Museum at Greenwich, and the Deptford pumping station of the Metropolitan Water Board, where two Watt engines were on view. All these visits are instructive in that they show the advances that have been made in our knowledge of engineering design and construction during even a hundred years. But it is to be hoped that at some of its subsequent meetings the Society will deal with apparatus of electrical interest.

Their House in Order.

THE technical proceedings at the twenty-seventh Annual Convention of the Incorporated Municipal Electrical Association, of which we give a full and complete account elsewhere in this week's issue, fall naturally into three parts. Perhaps from the purely technical point of view it might be said that none of these parts was more important than the others. Sub-station design and the control of finance are obviously both questions that have not yet been given a final solution, and still present problems that require treatment. For that reason it is well they should be discussed. But looking at the matter from the broadest possible point of view, these two questions are completely overshadowed

by what may be conveniently called the subject of development. It is therefore fortunate that the PRESIDENT'S Address, with COLONEL VIGNOLES' Paper and the discussion thereon, formed a unit of opinion concentrated into one day of the meeting from which some very useful lessons can be drawn.

The Reiteration of Fundamentals.

THE PRESIDENT'S Address deals in generalities. It states fundamental propositions which have been stated before, stated so often, in fact, that they have become trite. But because a statement is trite it is not necessarily untrue; and it is sometimes well, if not essential, that it should be reiterated, and reiterated, until its lessons have been acted upon and it can be consigned to an honourable position in our mental museum.

The Tribute of Attention.

WHEN, for instance, MR. ALLEN announces that: "The electricity supply industry is indissociably wrapped up in other great industries," and that "Each section of industry, by its action or inaction, affects the destinies of other sections," the ordinary individual automatically brings into play his critical and cynical faculties, shrugging his shoulders in a depreciatory way at this glorification of the obvious. But do the majority of electrical engineers, whether they be connected with supply or manufacturing, or research or teaching, or selling, or with any other branch of the industry, always act as if that interdependence were ever present in their minds? They do not; because they do not realise its truth in practice, however much they may pay it the compliment of a depreciatory shrug. For that reason we are pleased that this obvious fact was stated by MR. ALLEN, by MR. HIRST at the luncheon given by the General Electric Company to the Convention, and by Dr. FERRANTI at the Annual Dinner. Such a body of opinion should be paid the tribute and attention and the still greater tribute of action. For if I.M.E.A. are really, as Dr. FERRANTI said, trustees for the electricity users, they must not run the risk of being treated as false trustees.

An Atomic Fable.

NOW SIR ERNEST RUTHERFORD, as we noted last week, has recently been telling us something about the constitution of the atom. The atom is composed of a large number of smaller, and to some extent antagonistic, bodies. These bodies are constantly in motion. They possess an amount of energy which is large but can with difficulty be released for useful purposes; and their actions and interactions, therefore, go far to neutralise their potential utility.

A National Service.

NOW analogies are not always exact, but our imperfect account of the modern atomic theory, and still more a study of SIR ERNEST RUTHERFORD'S Kelvin lecture, may be recommended as a fable (with a moral) to those who think that all is well with the electrical industry and that progress can be achieved by sitting down and waiting for it, with intervals for the exercise of their skill in tennis and golf. To quote MR. ALLEN again: "Directly we realise that electricity supply is a national service we also realise the opportunity of establishing between contending parties within the industry that confidence the absence of which may have been the cause of troubles and delays in the past."

Meeting a Universal Demand.

WE believe it was COLONEL CROMPTON who, a short time ago, said that what the electrical industry had to sell was electricity—a commodity that everyone would increasingly require. We suppose that this also is trite, but it certainly is not always realised. That is sufficiently evident from the discussion on COLONEL VIGNOLES' Paper, to which we have referred above. COLONEL VIGNOLES laid down, quite rightly, that the domestic load must be developed to supplement and to relieve the fluctuations in the power load, and that to do this means paying much more attention in the future to the small consumer and especially to encouraging him to employ more and more electrical apparatus. He lays down as essentials for this development propaganda, hiring, and a low price per unit.

The Scientific Tariff Bogey.

NOW a discussion on any or all of these points would have been both interesting and profitable. Yet what do we find? Speaker after speaker rising, not to suggest means for selling electricity but methods for discovering a tariff which shall be scientifically accurate and, at the same time, bring into the undertaking a fair economic return from each consumer. It is like the search for the Philosopher's Stone; and about as likely to succeed. What we want is the business, not the scientific, view point.

Waiting for the Future.

Then there is the reminiscent, or self-congratulatory speaker. We say this in no carping spirit. It is satisfactory to find that there are so many enthusiasts for development and so much enterprise is being successfully displayed. But these speakers do not seem to imbue their audiences with their enthusiasm, and to that extent they fail. In any event there is much more to do than has ever been done. Finally there is the type of man who is sure that the domestic load is a thing of the future, but proposes to wait for the future (and the perfect machine) before he does anything to help progress. The WATTS, the STEPHENSONS, the FERRANTIS have always been in a minority amongst us, but nowadays we seem, in addition, to have more than our fair share of Doubting Thomases. Coupled with these is the man who thinks there is nothing in the domestic load. It is wonderful to find how many of him there are among central-station engineers. But it is difficult to say anything about him that will pass the censor. We do not propose to try.

Get Rid of Pessimism.

One thing, however, is evident: the electricity supply industry must rid itself of pessimism, and, though it may seem a bold thing to say, of science, at least in connection with tariffs, electricity supply is a business, not a science, and requires business men to run it. The others must change their methods, as they could easily afford to do, or drop out. Fortunately there is this saving grace about the whole matter. The industry, partly wittingly and partly unwittingly, has, like Frankinstein, raised a monster. The public has already begun to demand cheap and abundant electricity. It will not rest until it is supplied.

What Cheap Electricity Means.

YET that, after all, is a poor thing to permit to happen to us. How much better would it be, in MR. HIRST'S fine phrase, to work and endeavour to inoculate England with electricity! Such an enterprise is abundantly worth while. It will mean the continued healthy growth of the electrical industry, and all the industries dependent upon it, which are the majority of the industries of the country. It will thereby mean the restoration of the world's trade and continued and permanent commercial prosperity.

F

The Choice of Steam Conditions in Modern Power Stations.

By L. C. KEMP, B.Sc. (Eng.) A.M.Inst.C.E.

DURING the last few years much thought has been given to thermo-dynamics in relation to the design of steam power stations, and considerable progress has been made in the improvement of overall thermal efficiency. Steam pressures and temperatures have been rapidly increased, and it is of interest that in this respect British has tended to be ahead of American practice. At the same time, it is a fact that the advantages derivable from a proper selection of steam conditions have not received adequate recognition, and it is only in comparatively few cases, among the most modern

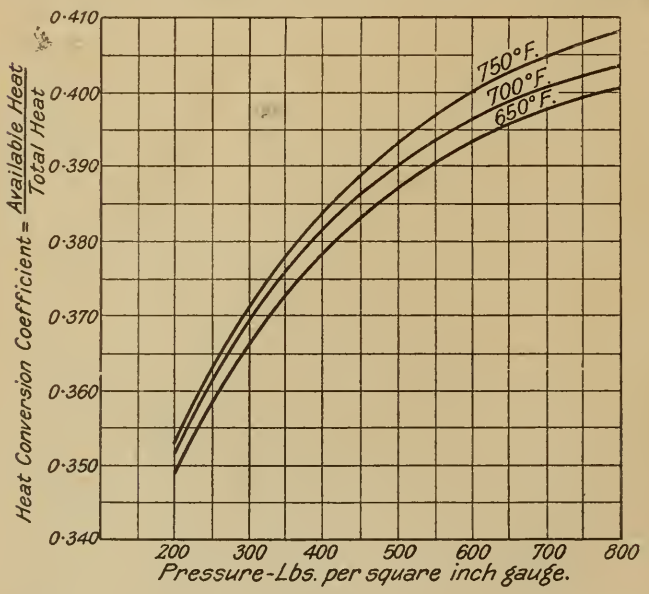

FIG. 1.—VARIATION OF HEAT CONVERSION CO-EFFICIENT WITH PRESSURE.

power stations, that the results of investigation into the subject have been put into practical effect.

Initial Steam Temperature and Efficiency.

The higher the initial temperature of the steam on its admission to a heat engine the better will be the efficiency of generation. This is due both to the greater proportion of heat available for conversion into mechanical energy and to the fact, in the case of the steam turbine, that the thermo-dynamic efficiency is, generally speaking, improved by an increase in the total temperature or superheat. Reciprocating engines are, for mechanical reasons, incapable of dealing with steam at the high temperatures now considered permissible, and this may be mentioned as one of the many well-known reasons for the choice of the steam turbine as the prime mover best suited to the requirements of the modern steam power station.

Thus the tendency in recent times has rightly been towards increasing the total temperature of the steam in the boiler house to the highest satisfactory working limit, compatible with the strength of the materials of construction at present at the disposal of boiler and turbine manufacturers. This safe working limit, which is largely a matter for individual opinion and discretion, is at present taken to be located between 650° F. and 750° F. There are some seven or eight power stations in this country operating with initial steam temperatures between 700° F. and 750° F., and with one exception no considerable trouble has been experienced. There is no doubt that all the difficulties incidental to temperatures near the higher limit have not been fully overcome, but recent experience leads us to expect that when minute care is given to every individual detail in the boiler house, steam pipeline and joints, valves and turbines, the difficulties can be met and advantageous results obtained.

The Selection of Steam Pressure.

Having decided upon the total steam temperature for which a new power station is to be designed, a considerable range of working pressures is open for selection. Under these conditions an increase in pressure is accompanied by an improvement in the proportion of heat available for conversion into mechanical energy, but, unfortunately, at the same time this is offset to some extent by a decrease in the superheat carried by the steam and by a drop in the thermo-dynamic efficiency for which the turbine can be designed.

It is intended in the present article to make an examination of the various effects on the economy of electrical generation in a power station when the steam pressure is increased whilst keeping constant the selected total temperature. In approaching the subject it is well to bear in mind the processes of heat conversion which occur in a power station between the coal entering the boiler furnaces and the electricity leaving the turbo-generator.

The Thermal Efficiency Chain.

The overall thermal efficiency of a power station may be represented by a chain of the thermal efficiencies of the individual units of plant comprising the power equipment.

In general terms,

Overall Thermal Efficiency of a Power Station (based on units sent out) = Average boiler efficiency α.
× Station co-efficient β covering radiation, leakages, steam for auxiliary plant, and boiler blow-down.
× Station co-efficient γ representing the ratio of units sent out to total units generated.
× Heat conversion co-efficient δ (or Rankine efficiency) representing the ratio of the adiabatic heat drop to the total heat in the steam.
× Average turbine thermo-dynamic efficiency μ.
× Average alternator efficiency η.
= $\alpha, \beta, \gamma, \delta, \mu, \eta$.

The efficiencies α, μ, η will be average values dependent on the load curve and the degree of care exercised in the supervision of the plant.

The value of the heat conversion co-efficient is of the order of 30 to 40 per cent., depending on the steam condi-

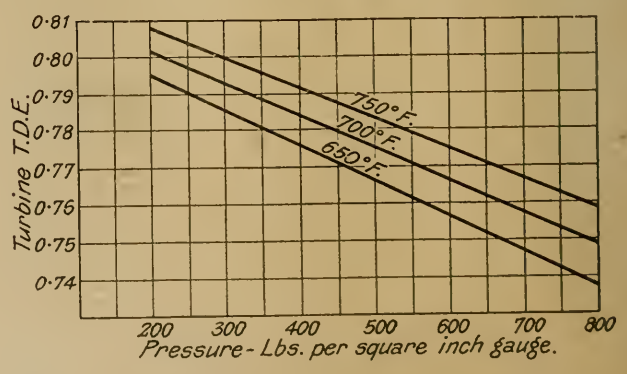

FIG. 2.—COMPARATIVE TURBINE T.D.E. AND PRESSURE

tions, whereas the other efficiencies and co-efficients are of the order of 80 to 95 per cent. For this reason an improvement of the conversion factor by 1 per cent. has a relatively greater effect upon the overall thermal efficiency of the power station than the same per cent. improvement in the efficiencies of the boilers, turbines, or station co-efficients, and, furthermore, a greater range of variation is obtainable with the conversion co-efficient.

Effect of Variation of Steam Conditions.

Variations in the steam conditions will affect the thermal efficiency of the power station mainly in respect of the heat conversion co-efficient and the turbine thermo-dynamic efficiency. The efficiency obtainable from water tube boiler plants of first-class design and manufacture will not be altered by increases in steam pressure, nor will the station co-efficients be appreciably affected. Experience so far obtained in the operation of high-pressure water tube boilers tends to show that maintenance and repair charges are no higher than for standard boilers designed for the more moderate pressures. The cost of the power equipment will, however, be increased for the higher steam pressures, and this fact must be taken into account in deciding the particular steam conditions at which a correct balance between first cost and thermal efficiency is obtained.

Effect on Heat Conversion Co-efficient.

For any given value of total steam temperature increases in pressure will be accompanied by a reduction in the

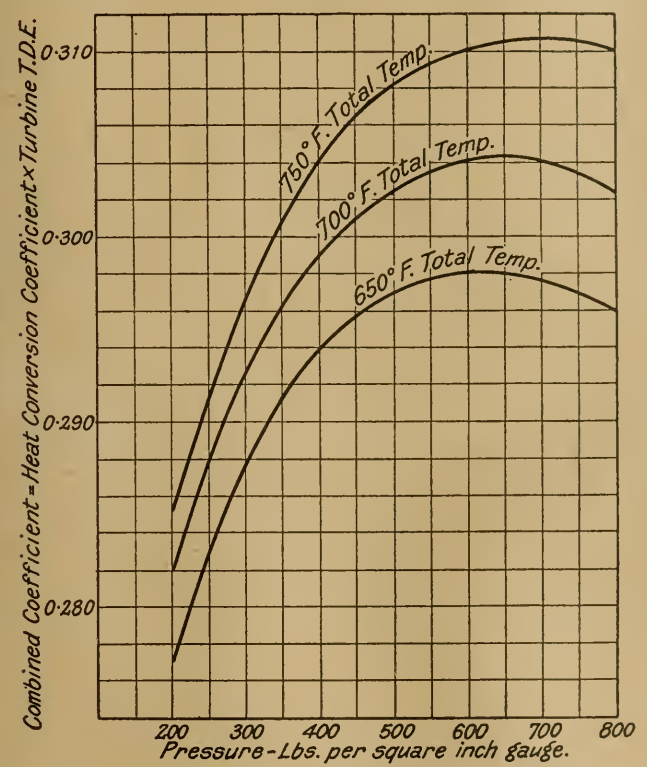

FIG. 3.—COMBINED CO-EFFICIENT AND PRESSURE CURVES.

superheat carried by the steam and an increase in the available heat or the adiabatic heat drop. The total heat shows only small variations, and is in fact slightly reduced at the higher pressures.

This is shown clearly in Table I., in which the values of superheat, available heat, total heat and heat conversion co-efficient have been tabulated for boiler pressures between 200 and 800 lb. per square inch and for constant total temperatures of 650, 700 and 750° F. The available heats have in each case been based on a vacuum of 28·7 in. (Bar. 30 in.).

To show the way in which the heat conversion co-efficient varies with steam pressure, the curves in Fig. 1 have been plotted. From this it will be seen that increases in pressure for constant total temperature improve the conversion co-efficient, but that the rate of improvement diminishes at the higher pressures. For example, taking the total temperature of 700° F., the same improvement in conversion co-efficient is obtained for increases in pressure between 200 and 350 lb. per sq. in. as between 350 and 700 lb. per sq. in.

Effect on Turbine Thermo-dynamic Efficiency.

In examining the thermo-dynamic efficiency for which a turbine may be designed under varying conditions of steam pressure and superheat it is necessary to consider individually the effect upon the principal losses which occur in the turbine, namely :—

(*a*) Hydraulic losses in the fixed and moving blades.
(*b*) Mechanical losses.
(*c*) Gland losses.
(*d*) Disc frictional losses.
(*e*) Wetness correction.

The hydraulic efficiency is inherently dependent upon the ratio U/C_0 of blade speed to steam speed, and thus, if the disc diameters and the number of stages are not considerably altered, a rise in pressure will have the effect of increasing the steam speed between each stage and cause corresponding reduction in the ratio U/C_0 and the hydraulic efficiency. The actual loss from this cause is not very great, and in fact does not exceed 5 per cent. over the whole pressure range considered, even when the disc diameters and number of stages are allowed to remain unaltered.

Mechanical Losses and Higher Pressures.

The mechanical losses, representing bearing friction and the power required to drive the governor and oil pump, are not effected by changes in the steam conditions. Gland losses are certainly increased for an increase in pressure but not to a very considerable extent. For example, the gland

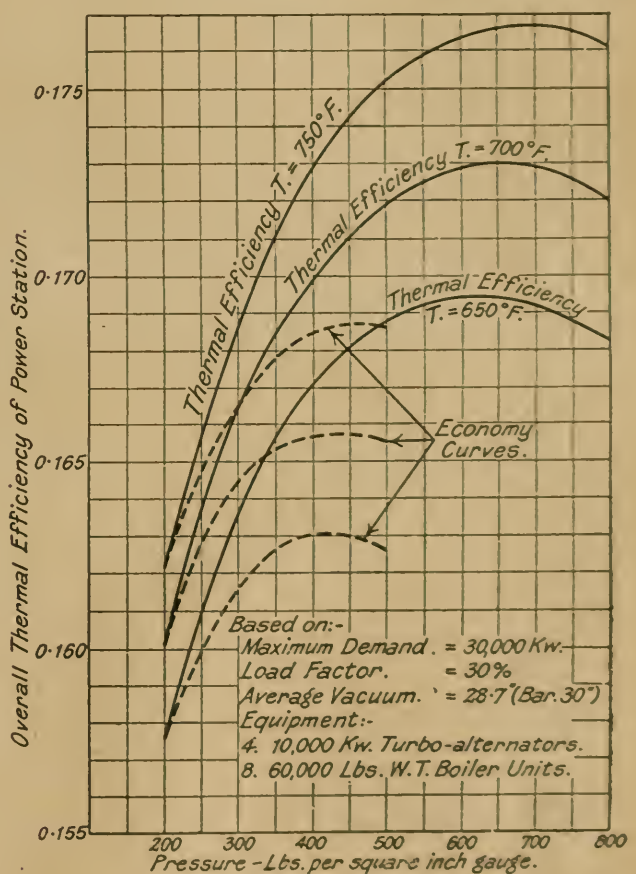

FIG. 4.—CURVES OF THERMAL EFFICIENCY AND THERMAL ECONOMY, APPLIED TO A PARTICULAR POWER STATION.

losses in a 20 000 kW turbine designed for 200 lb. per sq. in. working pressure would be about 0·5 per cent., but even with considerably increased boiler pressure the gland losses would not be more than 0·65 per cent., and this small difference could in practice be reduced by suitably increasing the length of the glands.

Disc frictional losses increase with pressure but not quite in proportion to the increase in the initial pressure of the steam, for the reason that a greater proportion of the increased pressure would in all probability be taken across the first stage of the machine with the object of limiting the high pressures and temperatures to a comparatively small portion

of the high pressure end of the turbine casing, and so avoiding many mechanical difficulties. Such a practice would also tend to keep down gland leakages as well as disc frictional losses.

The wetness correction has the greatest influence on the overall efficiency. The superheat is reduced at the higher pressures, and a corresponding increase occurs in the percentage of moisture in the steam passing through the later turbine stages. Thus, for a constant total temperature of 650° F. the effect of increasing the pressure from 200 to 700 lb. per sq. in. would be to increase the final percentage of moisture from about 7 to 12 per cent., and a correction of approximately 3½ per cent. on the overall efficiency would become necessary.

Fig. 2 shows the change in turbine thermo-dynamic efficiency which is brought about by variations of pressure at constant total temperature. These curves are based on the above considerations and apply particularly to turbines of 10 000 kW capacity. For the purpose of showing relative, as opposed to actual, turbine efficiencies they may, however, be taken to apply to all standard sizes of turbines between 5 000 kW and 20 000 kW capacity. It is seen that the overall turbine efficiency is reduced some 4½ per cent. for an increase in pressure from 200 lb. per sq. in. to 700 lb. per sq. in.

Pressure Variations and Thermal Efficiency.

In order to show the effect on the overall thermal efficiency of the power station it is necessary to multiply the conversion co-efficients by the corresponding turbine efficiencies. This operation has been carried out in Fig. 3, which shows the combined co-efficients for the various pressures. A point is reached round about 700 lb. per sq. in. where a maximum value is obtained for the combined co-efficient and thus also for the thermal efficiency of the power station.

Effect of Increases in Capital Cost.

The main items of plant to be affected in this respect will be the boilers and steam pipework. The turbines will also be rather more expensive at the higher pressures due to the heavier steel castings at the high pressure end and to possible additions to the number of stages. On the other hand, the capacity and surface of the condensers will be slightly decreased by reason of the reduced steam consumptions at the higher pressures and this will tend to offset the increased cost of the turbines.

Standard types of water tube boilers with integral superheaters and steel economisers are suitable for all pressures up to 450 lb. per sq. in. without serious modification except in respect of the dimensions of the tubes and drums.

TABLE II.

Working pressure — lb. per sq. in.	200	250	300	350	400	450
Approx. cost in £ per 1 000 lb. per hour steaming capacity.						
(*a*) 50 000 lb. capacity units	176·0	180·5	184·5	189·0	193·5	198·0
(*b*) 72 000 lb. capacity units	159·0	163·0	167·0	171·0	175·0	179·0

In Table II. approximate figures are given to show the extent of the increase in the cost of Babcock and Wilcox type C.T.M. steel cased boiler units of 50 000 and 72 000 lb. capacity, designed in each case to deliver steam at a total temperature of 700° F. It is seen that for every 100 lb. per sq. in. increase in pressure the first cost of the boiler installation would be increased some £8 to £9 per 1 000 lb. per hour in steaming capacity. This applies only within the pressure limits stated, since the standard type of construction could not conveniently be used for pressures above 450 to 500 lb. per sq. in. Radical modifications in design then become necessary, with the effect of increasing the first cost by at least 15 per cent. above that for the standard type of construction. Thus between boilers of standard type designed for 450 lb. per sq. in. and boilers of a special type designed for 550 lb. per sq. in. the increase in cost would be in the neighbourhood of £30 per 1 000 lb. steaming capacity. The design of the steam pipework calls for special consideration at the higher pressures, and the amount of increase in cost would of course depend upon the layout and capacity of the power station.

The Cost Factor and Overall Economy.

The incidence of the total increase in capital cost upon the economy of generation will depend upon a number of local factors, of which the coal cost, load curve and thermal efficiency of generation are the most important.

Each addition to first cost attendant on increased pressure will involve the undertaking in yearly capital charges which correspond in purchasing power to a certain number of pounds of coal or units of electricity. Thus in their effect on the economy of generation the additional capital charges will tend to counteract the advantages in thermal efficiency obtained at the higher pressures as indicated by the curves in Fig. 3.

Each new power station will present a new set of working conditions and will call for special consideration in this respect, but in order to indicate the method of applying the correction for increased cost it is purposed to make calculations applying to a particular example.

Consider the case of a power station to be erected in a district calling for a maximum demand of approximately 30 000 kW at 30 per cent. load factor and designed to the following operating conditions :—

Units Installed.
4—10 000 kW turbo alternator units (one spare).
8—60 000 lb. capacity water tube boiler units (two spare).
Coal Cost—16s. per ton delivered.
Calorific Value—11 500 B.T.U.'s per lb.
Vacuum (yearly average) = 28·7 in. Bar. 30 in.

The aggregate steaming capacity would then be 480 000 lb. per hour and the total increase in cost of the boiler plant £4 000 per 100 lb. per sq. in. pressure increase for pressures up to 450/500 lb. per sq. in.

The increase in cost of boiler house headers, steam pipework, feed ranges and other items of auxiliary equipment

affected by pressure may be taken for a power station of this size to be about £3 per 1 000 lb. of steaming capacity for each 100 lb. per sq. in. pressure rise up to a limit of 500 lb. per sq. in.

Pressure—lb. per sq. in.	200	300	400	450	500
Additional capital costs—	£	£	£	£	£
(*a*) Boiler plant	—	4 000	8 000	10 000	12 000*
(*b*) Steam pipework, etc.	—	1 440	2 880	3 600	4 320
(*c*) Total	—	5 440	10 880	13 600	16 320
Additional capital charges (11 per cent.)					
£ per annum	—	599	1 197	1 496	1 797

On the basis of a selection of 700° F. for total steam temperature and using the combined turbine and conversion co-efficients from Fig. 3, cost factors may be obtained to represent the effect of the additional capital charges on the economy of generation by means of a calculation such as is shown in Table III. In this case the cost factor has been taken to be unity for 200 lb. per sq. in. working pressure, and it is seen that by increasing the pressure to 450 lb. per sq. in. the undertaking would be called upon to find additional capital charges to the amount of £1 496 per annum, or approximately 3 per cent. of the annual coal cost. This is economically equivalent to a 3 per cent. increase in coal consumption, and it is apparent therefore that an index to the thermal economy of generation is obtained by multiplying the thermal efficiency by the cost factor.

This operation has been carried out in Fig. 4, in which the curves of combined co-efficient in Fig. 3 have been reproduced to a new scale indicating the thermal efficiencies for the example now under consideration, and corresponding

TABLE III.

1. Pressure—lb. per sq. in.	200	300	400	450	500
2. Thermal efficiency of power station at 30 per cent. load factor per cent.	16·00	16·65	16·99	17·1	17·2
3. Coal cost—pence/unit	0·1592	0·1530	0·1500	0·1490	0·1481
4. Total units generated —millions/annum ..	78·84	78·84	78·84	78·84	78·84
5. Yearly coal cost, £ ..	52 300	50 200	49 200	48 900	48 650
6. Capital charges corresponding to increased cost of plant— £ annum	Nil	599	1 197	1 496	1 797
7. Ratio : $\frac{\text{Additional cap. charges}}{\text{Yearly coal cost}}$	Nil	0·0119	0·0243	0·0306	0·0369
8. Cost factor (based on unity at 200 lb./sq. in.) $= \frac{\text{Item 5} - \text{Item 6}}{\text{Item 5}}$	1·0000	0·9881	0·9757	0·9694	0·9631

economy curves added for total temperatures of 650° F. and 750° F. as well as for 700° F.

The steam conditions at which maximum economy of generation is obtained in this example would appear from the curves to be as follows :—

	A.	B.	C.
Selected total temperature °F. ..	650	700	750
Pressure—lb./sq. in.	400	430	450
Superheat	201	244	289

It is of interest to note that by taking 450 lb. per sq. in. pressure for Case C instead of, say, 250 lb. per sq. in., a saving would be effected equivalent to 1·32 per cent. in coal consumption or nearly £700 per annum after allowance has been made for additional capital charges at the higher pressure.

The Cost Factor and Working Pressures.

The cost factor has a very considerable effect in reducing the working pressures at which the economic maxima occur, and it is important that a correct estimate should be obtained of the additional capital charges and maintenance costs, if any addition to the latter is to be anticipated. The foregoing figures, although applying to a particular example, are helpful in so far as they indicate a method of arriving at a positive result, and show that the choice of steam conditions for any given power station can with advantage be based on calculations which take into account economic as well as thermo-dynamic considerations.

* Assuming water tube boilers and standard type for this pressure.

The Reheating Problem.

Mention must be made in this article of the revolutionising effect on steam conditions and the general design of power stations which will be brought about by a satisfactory solution of the problem of inter-stage reheating in steam turbines. Very large gains in thermal efficiency are promised both by reason of the augmented heat drop and the fact that the turbine efficiency can be maintained at a high level due to the comparatively dry state of the steam throughout its expansion. There is no doubt that such a power station, introducing into its design a successful application of inter-stage reheating, will utilise advantageously very much higher boiler pressures than those indicated by present practice, and a big field for investigation will be opened out in this direction.

In conclusion, the author wishes to express his thanks to the English Electric Company, Babcock and Wilcox, and Stewarts and Lloyds, for the assistance and information they have provided.

Review.

Protective Relays ; Their Theory, Design and Practical Operation. By VICTOR H. TODD. (London : Hill Publishing Co.)

Not many years ago the American electrical engineer was wont to pride himself upon connecting up his system "solid," to the exclusion of all automatic gear. British engineers, on the other hand, have always maintained that to ensure continuity of supply a minimum number of simple and reliable automatic devices were essential, in order that a faulty machine or feeder should be isolated from the system.

It is interesting to note the result of experience by these two schools of thought. The British engineer has succeeded in perfecting his protective gear, in the direction of still greater simplicity and increased reliability, whilst the American engineer has now gone to the other extreme and has devised a relay for almost every purpose under the sun.

The book under review treats of the protective relays manufactured by two firms only, but even so the number of varieties dealt with is so large as to bewilder anyone in search of the relay best suited to his particular requirements. However, to anyone wishing to know what relays can do, this volume will prove of interest.

It is stated in the preface that the book is intended "not only for the operator and tester who has a fair knowledge of electricity" but also for the "designer of the system." Whether the "designer of the system" is not to be credited with a "fair knowledge of electricity" is not clear, but even he should hardly require to be told that "the secondary terminals of a voltage transformer should never be short-circuited" or the windings will be burnt out.

The author rightly emphasizes the importance of a minimum time lag at heavy overloads in the case of inverse time lag relays, but he does not point out that for feeder protection a momentary overload is unlikely to occur and that, for such purposes, a definite time lag can often usefully be employed. The reason for this omission is doubtless that the only definite time lag relay with which he appears to be familiar is the "bellows" pattern, which he rightly disparages.

The most difficult systems to protect—in fact the only systems which present any real difficulty—are those forming a ring main, which the author dismisses in less than two pages. The directional relay with graded time lags, which is the method of protection advocated, is certainly a very excellent one ; but there are others—the Merz-Price for example. This latter system is briefly described in another part of the book, but no mention is made of the difficulties which occur with it owing to capacity currents, or how their effects can be eliminated. The author is evidently averse, and rightly so, from using pilot wires at all, if they can possibly be avoided.

It is easy to criticise a treatise written to meet the conditions ruling in another country—conditions which necessarily differ very widely from our own, but in any case the author is to be congratulated upon producing a volume which, although it may not contain much that is actually new, deals with a subject of great importance and on which the existing literature is excessively meagre.

KENELM EDGCUMBE.

Recent Tendencies in Switchgear Design and Manufacture.

By J. R. COWIE.

Amongst the many developments during the past ten years those relating to power station switchgear are outstanding. Designs may be classed under two headings for comparison :—

(1) Armourclad gear embodying the total enclosure of all conductors in earthed metal cases.

(2) Cell structures of brick or stone housing and supporting bare conductors and apparatus.

The first is a development introduced to give complete safety in handling, compactness, and therefore economy in buildings, ready accessibility of essential parts, robust construction and a minimum of cleaning and maintenance.

Disadvantages of Cell Structures.

The present-day examples of the second may be taken as representing an improved arrangement of the earlier designs without eliminating the disadvantages. Conductors are partially protected by providing phase and busbar barriers, but the size of the structure becomes alarming when dealing with large capacities or when operating with the higher voltages. Many improvements have been made in the switches used for this class of work, principally in the employment of cast steel instead of cast iron on the switch top plates and in the strengthening and ribbing of the oil switch tanks.

Another point to which more attention is being paid in some designs is the screening of all live metal, especially on the oil switch tops. But with this class of gear it is almost impossible to provide efficient interlocks between the many parts and so ensure correct sequence of operation. In the early designs the most frequent cause of accident was the opening of air break isolating switches on a wrong panel—*i.e.*, on isolators carrying load, and such operation mistakes have resulted in serious damage to buildings, switchgear, structure, and in some instances loss of life.

Maintenance, cleaning, etc., is an expensive item, which has usually to be carried out at night or during the week ends, and is a source of worry to the engineer in charge until the last cell doors have been closed.

Dusty Insulators.

Especially with the higher voltages, leakages across dusty insulators may give the engineer in charge quite an uncomfortable time until this defect has been located and rectified. As a result, in many large stations complete enclosure of transformer and alternator terminals is being called for.

Evolution of Armourclad Gear.

These difficulties were appreciated in the early days of switchgear development, and an armourclad switchgear unit was produced primarily for use on the North-East Coast Power Companies' systems. The growth of the use of this equipment has been phenomenal, and enormous savings in cost have been effected : in buildings, in maintenance staff ; by convenience in handling ; by interchangeability of parts, simplification of erection, and immunity from operators' errors in the manipulation of isolating switches owing to effective interlocks. The manufacturers being satisfied that these features were of importance to the industry, apart from their commercial value, larger designs to cover wider applications were made, and various medium-sized power stations were equipped throughout the country, one of the earliest power station equipments being at the Stepney Borough Council's Osborne Street generating station.

In 1912 Mr. S. E. Fedden decided to instal a large armourclad switchboard in his Neepsend Power Station, this being the first installation for a really large station. Twelve panels were first erected, as shown in Fig. 1 (1 and 2). Certain novel features are evident from the photographs. The operating or control board overlooks the turbine room with the switch house immediately behind it, the separating wall fulfilling the double duty of a partition and a substitute for the usual slate panels. The wall is tiled with dark vertical bands between the panels, and all the instruments, relays, operating mechanisms, etc., are mounted directly on the wall. The switchgear is of very massive construction, particularly the oil circuit breakers, as may be seen by reference to Fig. 2. Duplicate bus bars are provided, either of which may readily be connected through the oil circuit breaker to the outgoing or incoming cables *via* the transformer chamber, which houses any required combination of current transformers.

Switchgear Details.

The essential parts of the switchgear may be divided into the " fixed " and " movable " portions, as follows :—

Fixed Portion.—(1) *The Bus bars*—Each set of three bus bars is mounted in a cast metal chamber and is supported from the main frame standards. Each bus bar is connected to a socket supported by a large tubular insulator fixed in a spout-like aperture to the front of the chamber.

(2) *The Transformer Chamber* is mounted immediately below the bus bar chamber, and is provided with similar spouts and sockets to the latter. The size of the chamber depends upon the number of protective gear and instrument transformers required. A potential transformer of the totally-enclosed oil-immersed type is mounted in front of the chamber and is connected through plug type e.h.t. fuses which pass through insulators embedded in the hood of the transformer case and the main chamber.

A cable dividing box with the requisite number of glands is mounted on the lower side of the transformer chamber, or spur connections may be taken through the wall behind or through the floor.

Movable Portion.—(3) *Oil Circuit Breaker.*—Despite the size and weight of the oil circuit, effective means of handling are provided. The breaker is of the " carriage " type and may be moved backwards and forwards on the main frame supporting standards through the agency of rollers and a rack and pinion device which is actuated by a ratchet lever. This movement affords means for completely isolating the circuit breaker or the cables from the bus bars. The plug contacts seen in the illustrations projecting from the front of the switch engage with the sockets in the fixed chambers bus bar and transformer chamber and therefore to the cable. The movement of the oil circuit breaker actuates folding doors, which cover the spout openings of the fixed chambers when the circuit breaker is withdrawn, in order to prevent access to live conductors.

Mechanical Strength of Tank Necessary.

A portable truck with a moving platform is used for lowering the heavy tanks when a circuit breaker is withdrawn, or for moving a switch bodily. These circuit breakers have dealt with some severe faults close to the bus bars with complete satisfaction. Extensive experience under actual operating conditions has conclusively proved that great mechanical strength of the tank and supporting top plate, a large volume of oil and extremely rapid motion of the separating contacts through a moderate distance are necessary.

Too much reliance is apt to be placed on the cushioning effect of the air above the oil, and whilst this is of certain value, mechanical strength must not under any consideration be sacrificed in its favour. Adequate vent pipes suitably baffled to prevent undue discharge of the oil are a further safeguard against the high internal pressures established.

It should be mentioned here that with the heavy steel tanks used a solid web some 3 in. by 2 in. thick is formed round the top of the tank (see Fig. 2) to give a secure fixing to the supporting studs, and further to prevent the emission of oil or flame at this point, which is between two machined surfaces.

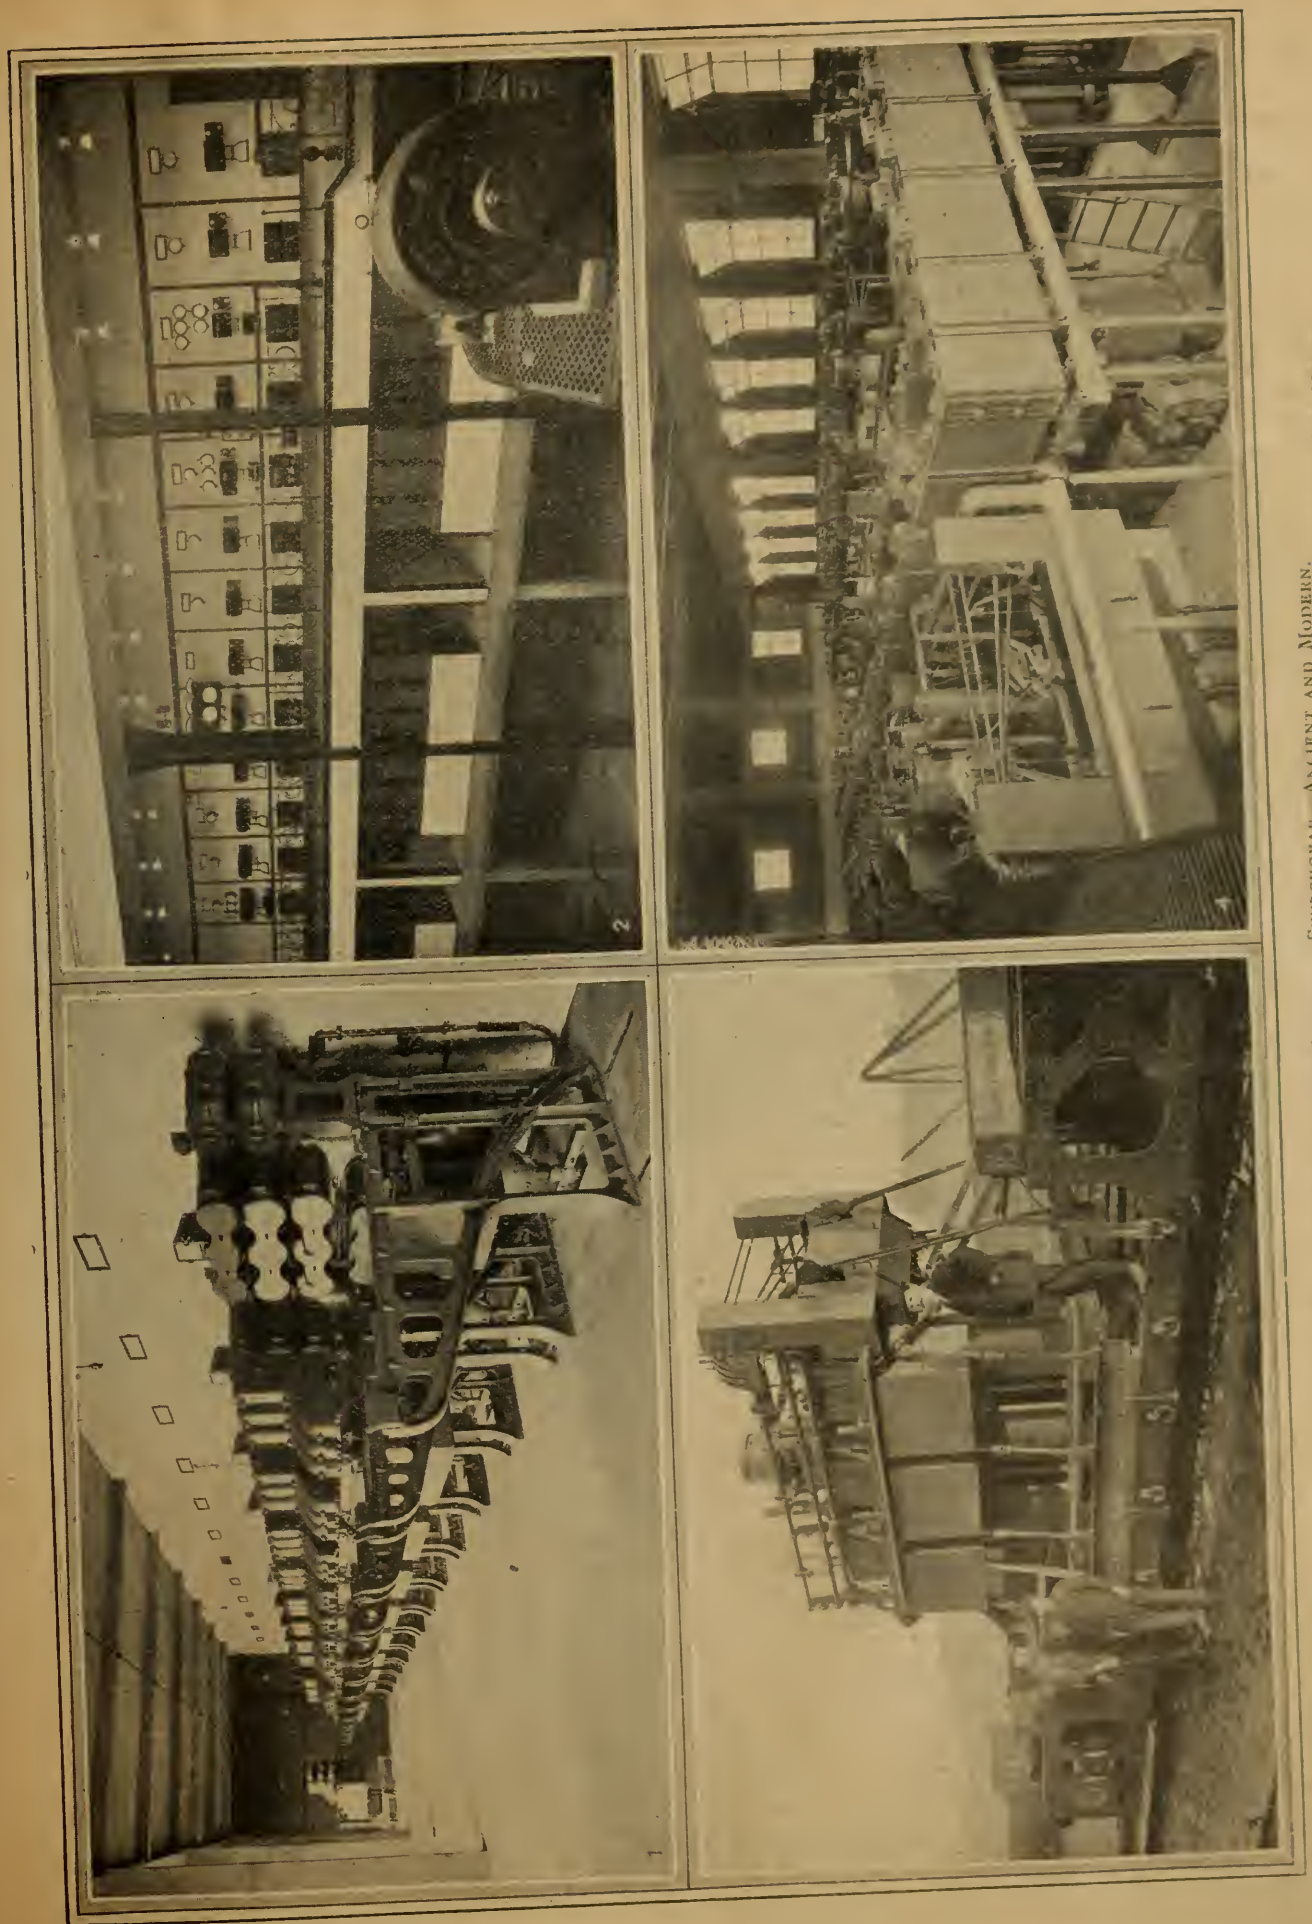

FIG. 1.—SOME VIEWS OF IRONCLAD SWITCHGEAR—ANCIENT AND MODERN.
1. THE SWITCHES AT NEEPSEND STATION, SHEFFIELD.
2. THE SWITCHBOARD AT NEEPSEND.
3. THE LATEST SWITCHGEAR FOR CARVILLE.
4. A MODERN SWITCHROOM.

Speed Rather than Length of Break Important.

Yet another important feature in the actual oil switch itself which has not been previously mentioned is that within limits, provided that the speed of operation of the switch be fast enough and the containing tanks and structures strong enough, length of break is not an important criterion in the rupturing capacity of the oil switch, but speed of break is. This has been proved by experience in this country and has recently been confirmed by experiments on the Continent, thus proving that an armour-clad switch of high velocity is a better switch than a more lightly clad switch of slow breaking velocity and with a long break.

Super Power Station Gear.

About 1915 it was found that a much larger type of switchgear was necessary to meet the requirements of the super power stations then under consideration. The illustration Fig 1 (4) shows a switch room with twenty-eight

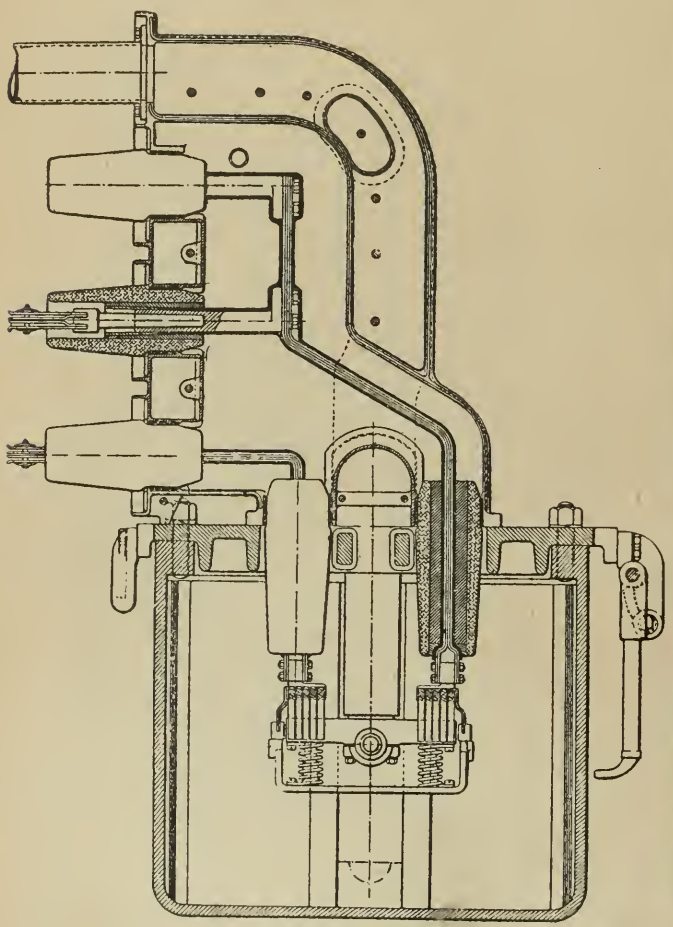

Fig. 2. Details of Oil Switch (1912).

switches, each switch having a rated rupturing capacity of 1 500 000 kVA. These are at the moment the largest switches that have been constructed. Fig. 4 illustrates the control room of these switches with their instruments, telegraphs, and visible indication of the operation of the salient parts of the switch panels. To meet these requirements a special design was prepared and models were made on somewhat different lines to those previously described, but retaining all the salient principles.

An illustration of a typical equipment is shown on Fig. 1 (3) It may be noted that complete assembly of the unit may be made in the shops, so that erection work on site is reduced to an absolute minimum. The photograph 1 (3) was taken as the unit was leaving the works for Carville Power Station, and pending the completion of the switch house it was erected with five other units in a corner of the engine room. It is difficult to imagine how an equivalent equipment in a stone cell structure could be similarly used without incurring enormous expense. It is necessary to make special arrangements with the railway authorities for the transport of complete units owing to their dimensions, but by partially dismantling them ordinary trucks may be used.

General Design and Construction.

Before describing installations of this class of gear, a brief summary of the objects of design and general construction is desirable. The fundamental object in the design has been to attain a high degree of safety from every point of view, and at the same time to render all parts requiring inspection readily accessible. This is obtained by the adoption of the draw-out feature and a complete system of interlocking ; the latter has been applied to the extent of rendering it impossible to obtain access to any live conductor without deliberate mechanical interference. The

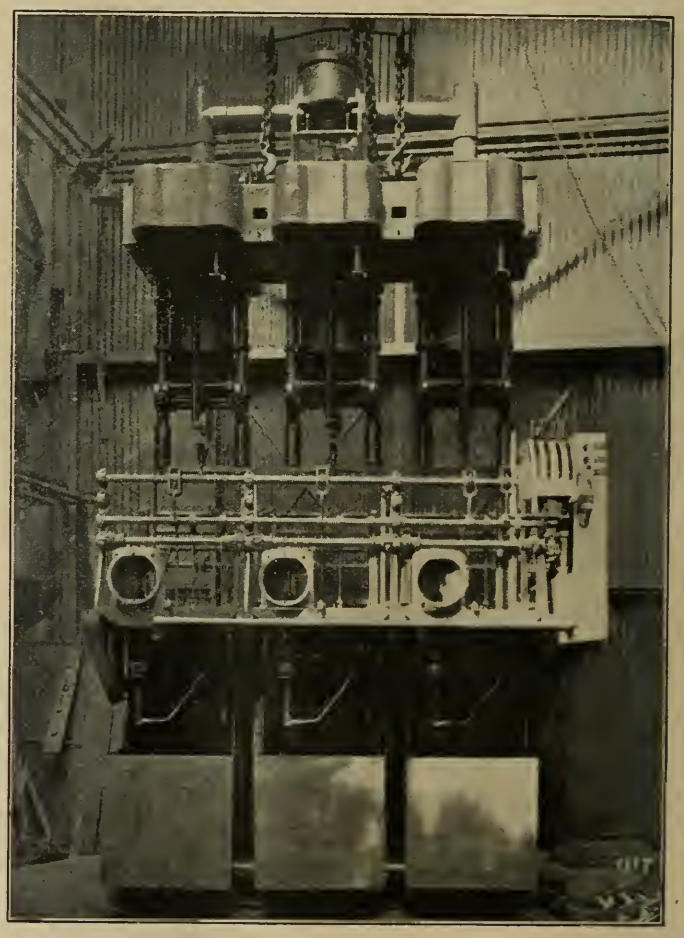

Fig. 3.

interlocks equally assure the correct sequence of operation of the various switches.

The general construction of a panel is shown in Fig. 3, which depicts a compact three-phase unit with separate metallic enclosures for each phase. The central tanks are steel cylinders of great mechanical strength, which contain the main circuit breaking parts. The rectangular tanks on either side contain the incoming isolating switch with instrument transformers and the busbar selector switches respectively.

The bus bars are arranged between two lines of panels, and each bar is insulated with varnished cloth, surrounded by a metallic earthed case, which is then filled with insulating compound.

Arrangements of Sparking Contacts.

A striking characteristic of the oil circuit breaker is the arrangement of the sparking contacts. The arc on breaking circuit is substantially horizontal with a large unobstructed

head of oil above it. A bell-mouthed vent in the top casing immediately above the break leads through large steel pipes fitted with non-return valves on each panel. The sparking contacts are attached to the ends of substantial arms so arranged that a relatively small movement of the main contacts gives a large movement to the sparking contacts in opposite directions, thus the speed of break is extremely high, due to the sum of the velocities of the arms moving in opposite directions. Further, the conductors supporting and forming the sparking contacts are ingeniously arranged to form a complete loop in the path of the current ; the resultant electro-magnetic forces elongate the arc and impel it upwards. (Gregory's Patent No. 111 766 of 1917.)

Means of Inspection.

For convenience in inspection, the removable portion of a panel, comprising the massive top plate carrying the solenoid operating mechanism, one set of isolating switch contacts on either side, and all movable parts of the main

Automatic Earthing Device.

In connection with earthing, a further detail is of interest in that all isolating switch tanks when lowered, automatically operate a lever which earths conductors within. Interlocks prevent the tank being lowered (Coates and Mirrey's Patent No. 122 443 of 1919) unless the enclosed conductors are dead, so that a double safeguard is afforded. The interlocks also provide operation of all parts in correct sequence. Reference to Fig. 3 will give a clear idea of the general construction, though lack of space prohibits a detailed description.

Control Board Construction.

A departure has also been made in the control board construction, as shown in Fig 4. Each panel consists of polished slate slabs mounted on the front of a dust-tight sheet steel cubicle in the form of a complete unit. The upper slates are enamelled white, with a bold diagram of connections in colours, all switches being represented by an

Fig. 4.

circuit breaker, may readily be raised by the crane provided for the purpose.

The separation of the conductors in both the fixed and removable portions (Clothier's Patent No. 110 808 of 1917) is made under oil, and metal screens automatically cover the apertures left in the fixed portion, so that whether the removable portion is in or out, all the live conductors are metal clad. The insulators are always immersed so that in no case is there dependence upon the insulation of the air. The whole framework is of earthed metal, which is securely bolted, so that a short between phases is rendered impossible.

Oil Circuit Breakers.

The oil circuit breakers are remote electrically controlled and the isolating switches are operated by hand from levers mounted on a pedestal accessible from the platform erected along each side of the panels. There is a separate lever for operating an earthing switch on the incoming conductors, to enable either phase of a feeder or generator to be substantially connected to earth. This switch is, of course, interlocked to ensure that the main isolating switches are open before conductors are earthed.

automatic indicator, so that during operation the position of any switch is seen at a glance.

The lay-out of these units is arranged for convenience with the units in four rows with the busbars between the outer rows and with a junction at one end of the building. This makes for compactness and small floor and building space.

The circuit breakers illustrated are the largest which have so far been constructed, and are installed in many of the large power stations in this country, including Dalmarnock (Glasgow), Carville (Wallsend), North Tees (Middlesbrough), Nechells (Birmingham). Their behaviour in these important situations has been very successful, and quite up to the manufacturers' expectations.

All-British Design.

It is gratifying to find that Continental and American practice is entirely superseded by an all-British design, although we gather from the American Press that the lead which has been given will soon be followed across the water. Concurrent with the developments of switchgear has been the steady progress made on discriminating auto-

matic protection devices for alternators, feeders and power transformers, all of which have been very fully discussed in papers read before the Institution of Electrical Engineers, and in the technical press, showing the importance that is attached in this country to the reliability of supply. Such discriminating protective gear has made it possible to link up feeders in parallel, and so utilise the cable capital expenditure to a much greater extent. Modern tendency, however, tends to divide a large city up into separate sections, and the cable lay-out in Glasgow has been designed to allow the city to be divided into four independent sections, so that in the event of any serious trouble on any one section of the plant, from the boiler house onwards, only one-fourth of the supply will be affected.

The Distribution Problem.

Another great problem which calls for switchgear of a very different nature to super station gear is the difficulty engineers are experiencing in adequately handling the large amount of power that is being used in modern buildings in a large city, owing to the very great increase of domestic appliances in the home. This distribution problem varies in various local areas, and it is interesting to note a suggestion by Mr. Woodhouse, in a paper before the Institution of Electrical Engineers, that the distribution voltage for consumers should be 3 300 V. The writer is in agreement with this view, which means that we are in this work returning to the days of the early pioneers, with this essential difference, that switchgear designs, naturally of a much smaller and special class, are in being ready to tackle house to house and building to building demand.

British Engineers Can Meet the Demands.

In conclusion, modern power stations call for the last word in efficiency in the boiler house, in the turbine room and auxiliaries. There is no useful purpose served if the switchgear installed be not of the same high standard as the rest of the plant. Reliability of supply means business from the large power users. British designers have had to face the problem of pouring power into densely populated areas and into cable net works connected, inter-connected and re-connected, so that experience in handling heavy fault currents is unique. The experience in using discriminating protection gear is unique. The switchgear itself, the safety valve of the whole system, is the result of long experience in handling difficult problems. Whether it be for low voltage work or for extra high voltage work British engineers are in a position to meet the demands of the supply industry, either in this country or from our kinsmen beyond the seas.

A Commentary on Power Station Switchgear.

By W. A. COATES.

The cost of buildings has fallen very rapidly during the last few months, so that to-day for a simple building such as is usually required for housing switchgear the price will hardly be more than 20 or 25 per cent. of the maximum figure reached during the war. This being so, the space advantage (with corresponding decreased building costs) enjoyed by ironclad switchgear is largely discounted in the case of new installations, and comparison between conventional cubicle structures and totally-enclosed ironclad equipments must be made more particularly on their technical merits. As a matter of fact, from the space standpoint it is often possible to accommodate gear in conventional cubicles occupying very little more space than an ironclad structure, when the cubicle design is approached with this end specifically in view. Present-day cubicle designs are to a great extent a legacy from days when minimum safe clearances were still indeterminate and plenty of space round all apparatus was considered essential.

Ironclad Switchgear Claims Examined.

Ironclad switchgear claims as its principal advantages: (*a*) Fool-proof features in operation; (*b*) immunity from attacks of vermin; (*c*) reduced maintenance; and (*d*) simplicity in erection. In power station work fully interlocked switchgear is probably not an unmixed blessing, since interlocks necessarily carry with them a certain degree of inflexibility. We have heard, for instance, of a generator having to be shut down to permit a potential transformer fuse to be replaced. In the power station are employed only skilled operators who can operate a conventional cubicle equipment with perfect safety. Where the switchgear is liable to be operated by semi-skilled persons interlocks are undoubtedly very valuable, and it is suggested that this is the principle field for gear of this class. Rugged mechanical interlocks are to be preferred to electrical devices which ultimately generally depend on more or less flimsy auxiliary switches.

Interlocks and Duplicate Bus Bars.

In particular this lack of electrical flexibility is found on those switching systems in which duplicate bus bars are employed. In cubicle arrangements the connection to the two bars is usually made by means of independent single pole selector switches, so that (especially when an oil circuit breaker is used coupling the two sets of bars) it is possible to transfer any circuit from one set of bars to the other without interrupting the supply. Due to the necessity for interlocks it is not possible on any ironclad switch structure to close the selector switches on to both bars simultaneously, and if it is desired to transfer a circuit from one set of bars to the other the current must first of all be interrupted. In a large power system this can sometimes be accomplished without actually interrupting the supply to a sub-station, by sending current round an alternative cable route, but even so the labour and time occupied in making such changes is distinctly greater than would be the case with a cubicle structure. It may be noted that some authorities have deliberately sacrificed this extra flexibility on their cubicle layouts and have used double throw selector switches so as to avoid any chance of the two bars being tied together inadvertently.

Saving Cleaners' Wages.

The next two advantages referred to—*i.e.*, the freedom from attacks of vermin and the smaller amount of cleaning required—are of course self-evident, and are distinct advantages in practically all locations. In some cities the latter point may conceivably enable at least one cleaner's wages to be saved, where much switchgear is installed. Ease of transportation and erection is specially valuable for sub-station applications in rapidly extending areas. As the system increases in capacity the smaller units originally installed can be shifted towards the outlying districts and new units of larger breaking capacity purchased for the close-up sub-stations.

Ironclad Equipments require Higher Insulation.

In designing ironclad equipments a higher factor of safety is desirable on the insulation, not because this class of equipment is more liable to trouble in this direction, but merely because if trouble does occur it is more difficult to get at the conductors to repair the damage. In a conventional cubicle, should an insulator or a protective transformer fail, it is a comparatively simple matter to effect repairs.

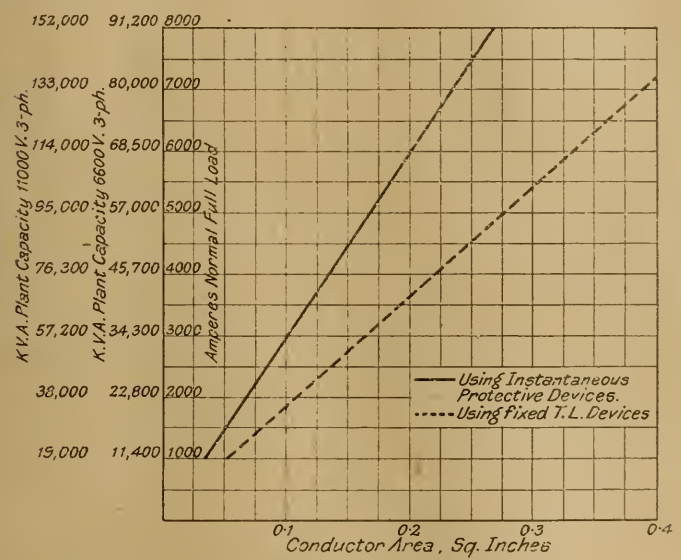
It would seem that at the present moment it is impossible to lay down any definite statement as to which class of gear should be used for a given location. The choice is very largely a matter for decision on the merits of each particular case, bearing in mind the class of operator which will be available.

Limiting Resistances and Potential Transformers.

A point to which considerable attention has been directed recently is the desirability of using limiting resistances in series with potential transformers which are connected off the main bus bars of a large power system. The short circuit current which may flow through the wires connected to a potential transformer should the h.t. terminals of the latter become short-circuited may very easily be sufficient to fuse the connecting wires themselves during the same period as is required to melt the protective fuses. Moreover, the fuses are generally distinctly limited in their breaking capacity. The carbon tetrachloride fuse is probably the best available, and it has shown its ability on very large systems to clear short-circuit currents which were limited only by the resistance of the fuse itself. The limiting resistance should be divided and placed half on each side of the transformer protected, immediately between fuses and bus bars. The actual ohmic value employed depends on the transformer characteristics, but it is usually possible to keep the maximum short circuit current down to 25 or 30 A and still maintain B.E.S.A. limits of accuracy in transformation.

Limitations of Limiting Resistances.

The use of limiting resistances for potential transformers does not safeguard the only point of danger, however, and



Minimum Sizes of Small Conductors on Large Switch Gear.

for very large systems there should be established a minimum cross-section of conductor which should be used to make any direct connection from the main bus bars. In a previous article* the writer showed some curves connecting short-circuit currents with conductor temperature. It is now suggested that on the switchgear of large steam-driven power plants the smallest conductor should not be less than indicated in the curves given herewith. These are based on an assumed alternator reactance of 10 per cent., and the possibility of a circuit breaker being reclosed on a short circuit after it has once tripped. The final conductor temperature would be approximately 500° C. under these conditions.

Series Transformer Design.

The series transformers used on the switchboards in large power stations should invariably be of the bar primary type on account of the risk when heavy short circuits occur of bursting transformers having wound primaries. Further, the copper sections used in small wound primary series transformers will often be much less than the minimum proposed above. Small feeders connected direct off the main switchboard may conceivably have normal full load currents such that a bar primary transformer is by no means correct, but accuracy in such a case should be put second to safety in operation.

* "Small Conductors on Bus Bars of Large Systems"—*Metropolitan-Vickers Gazette*, June, 1920.

Control Room Considerations.

There is a growing tendency towards using separate control rooms in connection with large stations. Although this is done it is still necessary to consider seriously what steps shall be taken to facilitate the work of the switchboard operator. The dummy diagram system which is so popular in America has not been used in this country to any very great extent. It is undoubtedly a great advantage where the switching system is at all complicated or where possible alternative paths of supply exist. It should not be used, however, except in those cases where the isolating switches are of the three-pole type, arranged so that when they are operated a corresponding indication is automatically given on the dummy diagram, either by means of a pilot light or an electro-magnetic indicator. The small hand-operated links sometimes put into dummy diagrams to represent isolating switches are a questionable advantage, since a man may easily forget to move them at the right time.

To bring the size of the control switchboard down to more reasonable proportions it can frequently be arranged that the controlling elements—*i.e.*, the indicating instruments, rheostat handwheels, oil circuit breaker control push-buttons and synchronising devices, are mounted on one board, while on a second board, frequently standing at the rear of the control board, are mounted all relays and integrating instruments. The equipment on this secondary board does not have to be adjusted or read save at infrequent intervals, so that there is no objection to it being located in a somewhat inaccessible position.

The Ideal Control Board.

While we are not within reach of it yet, it is suggested that the ideal will only be attained when we can get a desk control board, which is about the size of an ordinary writing-desk. In this case the indicating instruments would be similar to those which are used on the battery circuit of a motor-car. These could conveniently be located on the vertical part of the desk, leaving the horizontal surface for a series of small push buttons operating the various oil switches, and worked into the run of a miniature bus bar system in which pea lamps serve as pilot lights.

Dash board instruments, about 3 in. diameter, and of either moving iron or d'Arsonval pattern are already on the market. Extreme accuracy is unnecessary at the central control point, although in point of fact these little instruments can be built to the accuracy requirements of the B.E.S.A. First Grade. Development would be required for A.C. wattmeters, and power factor meters. A large synchroscope will probably always be desirable, so that the operator can see his position at a glance.

Hammersmith Mains Extensions.

Hammersmith Electricity Committee propose to spend £15,127 on the extension of mains. In March, 1920, the Council approved of the extension of the main distribution system to meet increased demands in the King Street and Starch Green districts and a cable which is now feeding the northern area of the borough, was laid from the generating station to Wood Lane, at a cost of £21,603. But as there is no stand-by cable, it is necessary to draw in a second main to form a ring, the estimated cost of which is £3,008. The load in the Hammersmith Road district has considerably increased and additional demands have to be met which are created by the supply required of the Post Office Savings Bank in Blythe Road and also additional requirements of the "Olympia" premises, having regard to their extension. The existing h.t. feeders are not capable of dealing with this additional supply, and the Electricity Committee concur in the recommendation of the Engineer that the Council should proceed with the arrangements for an e.h.t. supply to the "Olympia," where a sub-station could be equipped from which the existing h.t. system could be fed. The suggestion is to divert the proposed new feeder to Wood Lane *via* "Olympia," thus forming a ring main from the electricity works to Wood Lane, from there to "Olympia," and from "Olympia" to the works. A scheme for the extension of the l.t. distribution system is also to be carried out at an estimated cost of £1 994 10s.

The Development of Condensing Plant and Auxiliaries.

By J. H. SHAW, M.I.E.E.

To meet the requirements of large turbo-units demanding low absolute pressures and high rates of duty it has not been necessary to develop new types of condensing plant, or make radical changes, neither has it been necessary to depart materially from the design used for reciprocating engines.

There was ready for use the very excellent Edwards air pump. This is highly efficient as an air extractor for vacua up to 28 in. But the limitations of this pump are reached because it is impossible to keep the valves tight at extremely low pressures, while the clearance on the top of the bucket lowers the volumetric efficiency. The large bulk required for the bigger sets is also a disadvantage.

The Vacuum Augmentor.

Then Sir Charles Parsons introduced the vacuum augmentor which consists of a steam jet and an auxiliary condenser between the main condenser and the air pump. This augmentor increased the air-withdrawing capacity of the combination at low absolute pressures, thus decreasing the required displacement capacity of the air pump. The disadvantage of the vacuum augmentor is, that whereas the air pump takes almost the same amount of power to drive as without the augmentor, the augmentor itself takes about 1 per cent. of the steam consumption of the turbine.

Dry Air Pumps.

The advantages of withdrawing the air and water separately from the condenser, the water from the hottest part and the air from the coldest being recognised, different forms of dry air pumps were evolved. Among these whirling jets, plugs of water and water ejectors were developed for the purpose of withdrawing the air and included the Le Blanc pump, the Rees-Roturbo air pump, and the Muller-Jose ejector. All these are, however, being rapidly replaced by the almost universal steam jets.

Steam Jets Now Universal.

The best known of these latter class are the Le Blanc ejector and the Hick-Breguet ejectair. The first named was developed as a tandem ejector, the steam used by the first jet being compressed by the second jet. The result was that the steam consumption was high and the vacua varied, in the case of one with which the writer was acquainted, more or less with the steam pressure.

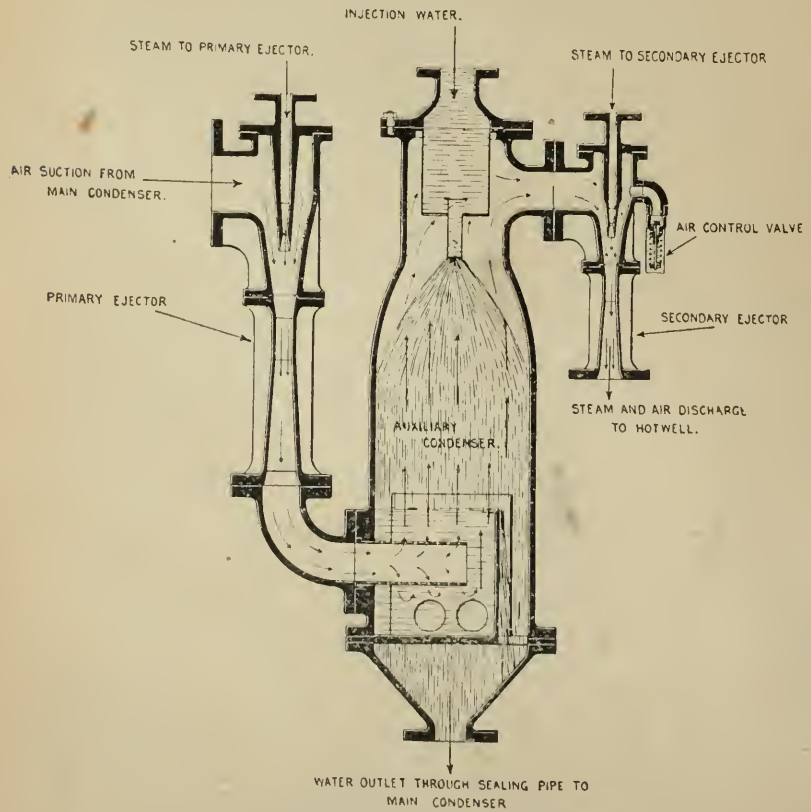


FIG. 1.—DIAGRAM OF THE HICK-BREGUET EJECTAIR.

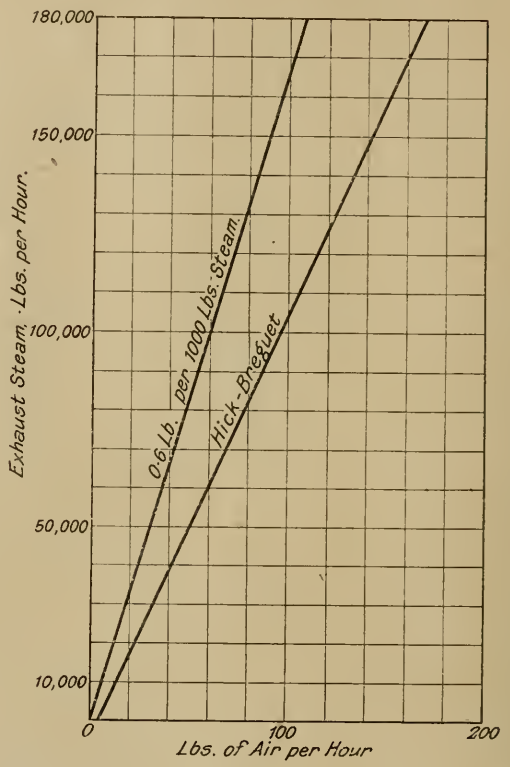

FIG. 2.—AIR CAPACITY OF EJECTORS FOR SURFACE CONDENSERS.

The compound Le Blanc and the Hick-Breguet ejectors are similar in appearance and design. In the first named there are numerous jets in each stage, whereas in the Hick-Breguet one steam jet is used in each stage. A cross section of a Hick-Breguet ejectair is shown in Fig. 1.

In this case an intermediate condenser is used to condense the steam used by the first or primary jet, the water for condensation being obtained from the discharge of the extraction pump, and the water and condensed steam being drained from the intermediate condenser by means of a U leg into the suction of the extraction pump.

The quantity of air to be withdrawn by an air pump attached to a steam turbine condenser depends on the type of low pressure gland used on the turbine and the layout of the condenser. It can be calculated by assuming 0·6 lb. of air at 60° F. per 1 000 lb. of steam. This formula and the Hick-Breguet formula are given graphically in Fig. 2.

Efficiency Comparisons.

There is little difference in the efficiency attained by the modern steam jet extractors, ejector or ejectairs, and for approximate calculations it can be assumed that with vacua between 28 and 29 lb. a steam jet extractor fitted with an intermediate condenser will extract 1 lb. of dry air at 60° F. for every 10 lb. of steam used and that the total consumption of the ejectair will amount to approximately 1 per cent. of the steam consumption of the turbine. One per cent. of the steam may appear to be high, but because all the heat units in the steam except those used for compression can, by the means of a feed heater, be absorbed

by the condensate the consumption of heat units is almost negligible. Roughly, 80 per cent. of the heat originally in the steam is taken up by the condensate, this 80 per cent. representing 1 000 B.T.U.'s per lb. of steam, and the ejectairs requiring approximately 1 per cent. for their operations means that the condensate temperature is increased by 10° F.

The arrangement generally adopted is illustrated in Fig. 3, which shows the U leg draining the intermediate condenser and the provision of a small heater to condense the discharge from the secondary ejector.

A later design of ejector is the De Las.* This requires the combining tubes to be water cooled, and water at a lower temperature than that possessed by the condensate is necessary for this cooling.

Extraction Pumps.

The water extraction pumps usually employed call for little comment. They are generally efficiently designed with large and well-arranged entrances pumping a comparatively small volume against a high head. Care should be taken that such pumps are installed so as to have a good head of water on the suction side. With such a low pressure in the condenser as 0·5 lb. absolute it is obvious that the water must flow to the pump by gravity. Usually 24 in. between the bottom of the condenser and the centre line of the pump is sufficient, but more should be allowed especially if there are any bends in the suction pipe.

Even if a reasonable head is allowed the discharge from all rotating extraction pumps is more or less variable or pulsating, as can easily be seen on any plant employing a Venturi water meter. It is recommended that where these meters are used an extra 12 in. is left between the condenser bottom and the extraction pump.

Little Development in Condenser Design.

The condenser proper has changed very little during the last twenty years. The size has, of course, kept pace with the demand for larger sizes of plant, and the diameter as a function of the length has increased until it is seldom less than half the tube length.

It is surprising that this quality of condenser design is not more universally recognised; even to-day condensers are installed in which the length is 2·5 to 3 times the diameter. A little thought would convince the technical buyer that with a long but small diameter condenser the ends of the tubes are performing very little duty, it being impossible for the steam to travel down the exhaust pipe at a velocity of 27 000 ft. per min. and abruptly turn through 90 degrees to seek out the ends of the tubes.

In order that the steam shall have access to the heart of the condenser and to reduce the pneumatic drop across the bank of tubes it is usual to arrange the centre of gravity of the tube mass eccentric to the centre of gravity of the bore of the condenser. This is clearly shown in Fig. 6

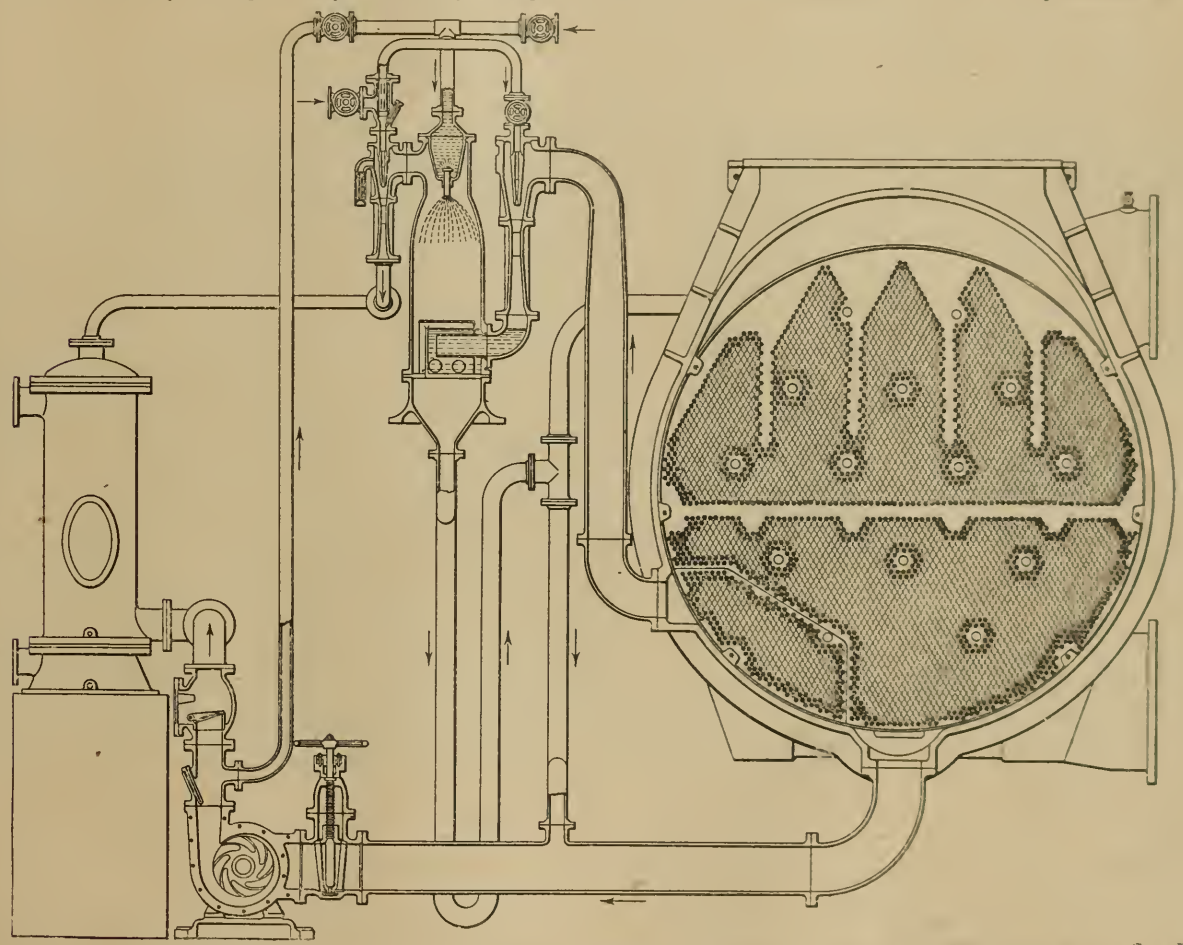

Fig. 3.—Sectional Arrangement of Typical Hick-Breguet Surface Condensing Plant, (Hick Hargreaves and Co Bolton)

This figure also illustrates Hick Hargreaves' latest design of tube plate. In the top half of the tube plate the ordinary pitch of the tubes is turned horizontal and makes a series of narrow lanes direct to the heart of the condenser.

The rating of condensers is, of course, being gradually increased, but perhaps not to the extent that the rating of other plant has advanced.

No Fixed Rules of Design.

In spite of the large amount that has been written upon condenser design, there are no fixed rules regarding the best shape, transmission rates, sizes of tubes, etc., and each manufacturing firm has its own data as to limiting rates of transmission, water velocity, etc. As an approximate guide to the comparative values of transmission rates, Hausbrand gives $K = 453^3\sqrt{v}\,v$ in English units, K = B.T.U.'s transmitted per square ft. per deg. Fah. mean temperature difference, and v = velocity in ft. per second of water in the tubes. This is high for British practice

* See The Electrician, June 16th, 1922, p. 718.

and very few condensers are to be found that are designed for such high rates of transmission. It is common practice to design for K equal to between 600 and 700 with v equal to between 6 and 7 ft. per sec. With some waters, for instance, those containing silt and fine mud, it might be advisable to increase the water velocity up to 10 and 11 ft. per sec., in order to prevent any settlement in the tubes. The transmission rate is again modified by the speed of the water particles and the condensed steam across the tubes, but no data that is readily applicable exists on this subject.

Condenser Costs.

A large condenser with the correct ratio between diameter and length will contain a larger number of tubes, and cost considerably more to build than one of small diameter, but containing the same surface.

A condenser for a 15 000 kW with 27 500 sq. ft. cooling surface and 16 ft. between tube plates will contain 8 770 tubes, whilst a condenser for 20 000 kW with 40 000 sq. ft. will contain 12 000 tubes. It is impossible during a week-end to clean such a condenser, and therefore the continuous service or twin box condenser has been evolved. The water box and return end are divided vertically, two circulating water inlets and outlets being provided. In this case one half the condenser can be shut off on the water side, only the steam space being common, and with the turbine running at about half load full vacuum can be maintained in the steam space whilst the doors can be removed from one half and the tubes cleaned.

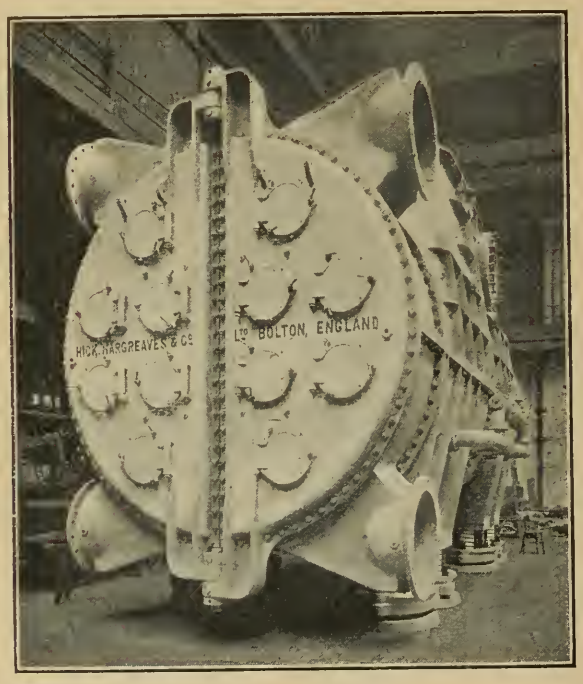

Fig. 4.—Hick Hargreaves Condenser with Patent Hinge.

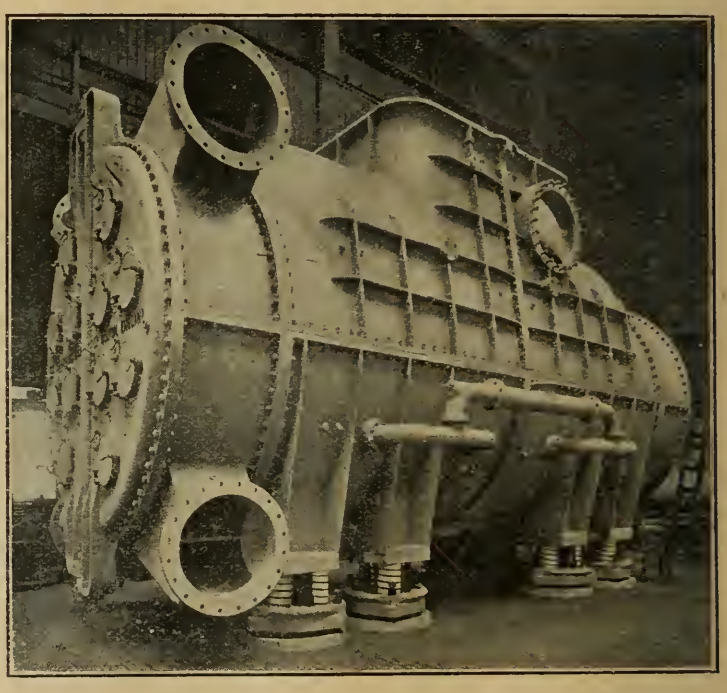

Fig. 5.—Hick Hargreaves Continuous Service Condenser for Shanghai.

Continuous Service Condenser.

A continuous service condenser, built for the Shanghai Municipal Council to condense the steam from a 20 000 kW set is shown in Figs. 4 and 5. The door is formed in two parts, the division being made on the vertical centre line. To enable the joints and the end box to be satisfactorily made it is necessary to provide for relative movement between the door and the end box, because if the doors were hinged on a fixed pin it would be impossible without considerable straining to satisfactorily make this joint.

The condenser shown in Fig. 4 is fitted with Hick Hargreaves and Co.'s patent hinge, which by means of eccentric bushes allows the doors to be moved bodily away from or towards the joint.

A detail of design which is now being appreciated is the sagging of condenser tubes due to insufficient support plates. A $\frac{3}{4}$ in. outside diameter condenser tube, gauge No. 18 thick, and 14 ft. 8 in. long, supported at both ends, will sag $3\frac{17}{32}$ in. when empty. The same tube supported at each end with two intermediate supports will sag $\frac{1}{16}$ in. when full of water, and $\frac{3}{64}$ in. when empty. If the tube, 14 ft. 8 in. long, has only one support plate in addition to the tube plates, the sag is $\frac{5}{32}$ in. when empty, and $\frac{3}{64}$ in. when full of water. It being inadvisable for water to be left standing in the tubes after a condenser is presumably drained, sufficient support plates should be fitted, so that the greatest span does not exceed 5 ft.

The Effect of High Steam Pressures.

The use of high steam pressures has increased interest in the necessity of preventing feed water from being contaminated by air, and the advisability of freeing all make up water of air or other gases. In many stations closed feed systems are being installed, and in others de-gassing plants.

A considerable number of power station designers are intending to or are actually bleeding the main turbine, at one or more stages, into feed heaters. Through these heaters the condensate is pumped and into the hotwells or feed pumps. The condensed steam is drained either into the condenser or the suction of the extraction pump. It is claimed that the reduction in overall heat consumption is a maximum when the feed is heated to 180° F. if only one feed heater per turbine is employed and that the reduction in consumption is approximately 4 per cent. If, however, multi-stage heaters are employed the reduction in heat consumption can be shown to be approximately 7 per cent. if the feed water is heated to approximately 300° F. If it is desirable to heat the feed water before it reaches the economizers, or if economizers are not to be installed the problem should be studied in connection with the driving of the auxiliary machinery.

House Turbine Condensers.

In order to obtain reliability it is necessary that a certain proportion of the auxiliary plant be steam driven. Small auxiliary turbines are, however, most uneconomical and troublesome. It therefore appears desirable that a house turbine be installed to supply power to the essential auxiliaries, such as circulating pumps, stoker drives, forced and induced draught fans, etc.

Such a turbine would have an output of from 3·5 per cent.

to 5 per cent. of the output of the main sets, and if direct current is required a geared set could be employed; if both d.c. and a.c. are necessary the generators can be arranged in tandem. The circulating water for this condenser would be the condensate from the main sets.

As the steam turbine would be of reasonable size and arranged to run at an economical speed the efficiency would only be about 10 per cent. less than the efficiency of the large sets, and providing all the heat rejected from the condenser can be absorbed by the feed water, the proposed arrangement is thermally perfect.

The objection to this system is that whilst the circulating water or condensate from the main sets is proportional to the load on the bus bars, the load on the house machine will be roughly proportional to the number of sets running. From this it will be gathered that during short periods of light load, when the time is too short to shut a large set down, the temperature in the house set condenser will rise, with a corresponding fall in vacuum. To overcome this difficulty

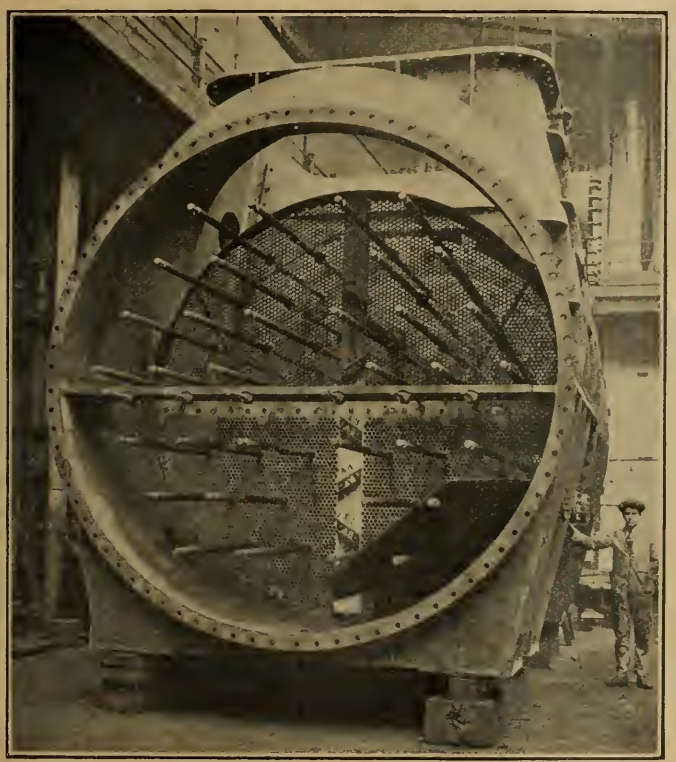

FIG. 6.—HICK HARGREAVES CONDENSER.

Hick Hargreaves and Co., have recently designed and patented a condenser which does away with this drawback.

House Turbine Economies.

In the Hick Hargreaves house turbine condenser, in addition to the connections and tubes for admitting and passing the condensate from the main machines, a small number of additional tubes are provided, and connections arranged on the water boxes for admitting an amount of circulating water at periods of light loads. The quantity of circulating water required to maintain the absolute pressure in the steam space of the house turbine condenser at a reasonable figure is quite small, and as the main machines are on partial loads when this condition prevails the circulating water can be drawn from the system without affecting the efficiency of the main sets. The waste of heat units will be negligible and the valve admitting the circulating water to the house turbine condenser can be controlled by a thermostat or by an electrically operated valve, worked from a control room or switchboard, or any other convenient method.

The steam space in the house turbine condenser would be one chamber, but the water spaces reserved for the condensate from the main machines and the water spaces for the circulating water would be kept quite apart.

The vacuum would be a function of the two water quantities and their temperatures.

In the event of a cessation of supply from the main sets the amount of cold circulating water could be immediately increased, thus enabling the auxiliary power to be maintained and immediate resumption of normal operation.

The present method of operating a house turbine when using condensate as circulating water is to run the auxiliary bus bars in parallel with the main bus bars, and at times of light load to transfer some of the load to the main machines. This is a dangerous method, as in the event of a shut down of the main sets the continuance of the auxiliary supply depends on the correct operation of a reverse power relay.

The Rutenberg Concession.

A discussion took place in the House of Lords on the 21st inst on the form of the PALESTINE MANDATE and the concession granted to Mr. P. Rutenberg for the development of water power.

The subject was introduced by Lord Islington who moved:—"That the mandate for Palestine in its present form is inacceptable to this House, because it directly violates the pledges made by his Majesty's Government to the people of Palestine, and is, as at present framed, opposed to the sentiments and wishes of the great majority of the people of Palestine; that, therefore, its acceptance by the Council of the League of Nations should be postponed until such modifications have therein been effected as will comply with the pledges given by H.M. Government." He complained that the Rutenberg concession, if allowed to materialise, would give to a Jewish community over an Arab community wide powers in respect of economic and industrial conditions for a number of years—powers in respect of water and electric power. It was quite obvious that the grant of that concession was not based on its merits, but on the deliberate policy of economic preference to the Zionists. They were jeopardizing the good feeling which had always existed between this country and the Arab community by adopting a policy, which he described as an unnatural, partial, and altruistic experiment.

In reply, EARL BALFOUR declined to go into the details of the Rutenberg controversy, as it would be debated in the House of Commons. The whole scheme was examined in the most critical spirit by the experts of the Colonial Office and they were quite unanimous that the terms and the character of the undertaking were such that there was no hope of any better contract being made than that which was offered by Mr. Rutenberg. The terms had been examined by persons who were not only disinterested, but also extremely competent. In the Rutenberg scheme there was nothing in the nature of undue favouritism, and if it could be carried into effect it would give economic advantages to Palestine which could be obtained in no other manner.

The terms of the concession were severely criticised by LORDS SYDENHAM and BUCKMASTER. The former said some of the terms of the contract were distinctly improper, and the latter complained that a special privilege had been granted to one person to go, as far as he could see, and exploit America and other countries for raising capital necessary to carry out an important engineering scheme. He did not doubt that that would be of the greatest value, and he had the greatest confidence that under Sir Herbert Samuel the monopoly would be fairly exercised. But that was not the point. Why was the offer not made publicly? It might be a good scheme, but in all these matters he was strongly in favour of public and open competition. He would have liked to see if there were not other people who would have given the necessary guarantees and might also have had the opportunity of interesting their capitalistic friends in embarking on this venture.

A Rival Scheme.

In connection with the criticism of the Rutenberg concession, a "Times" correspondent states that in the early summer of 1920 Suleiman Dabbub and other Bethlehem Arabs applied for a concession for (*inter alia*) electric light and power for Jerusalem and district. The application, which was put forward by the then Deputy Military Governor of Bethlehem, stated that they were already in possession of a capital of £500 000 and that they would have no difficulty in raising two million sterling or more if necessary. In reply to Suleiman Dabbub's application, Headquarters of the Administration replied that no concessions were being granted at the moment, but that the application would be considered later. Nothing further has been heard of it.

It is announced from New York that Mr. Rutenberg has been successful in raising the required capital from members of the Palestine Development Council and others.

According to the latest official survey there are sufficient waterfalls of 1 000 H.P. and over in the Island of Java to develop 303 000 H.P.; but in Sumatra about 1 200 000 H.P. is available, 500 000 in Celebes, and 375 000 H.P. in BORNEO, or a total of about 2 378 000 in the DUTCH EAST INDIES. At present only 49 000 H.P. has been developed, of which 47 000 is in Java, but two large nitrate plants, one of 200 000 H.P. in Sumatra and one of 50 000 H.P. in Java, are projected. The islands are rich in minerals, and with the expansion of the rice, sugar, tea and rubber industries the demand for electrical machinery and apparatus is likely to be a growing one.

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

A Successful Gathering in the Midlands—Ideas on the Domestic Load—Finance and Substations.

Monday, June 19.

The opening of a MUNICIPAL ELECTRICAL ASSOCIATION CONVENTION is always rather like the first day of school. It is a time when old friendships are renewed and when a certain amount of justifiable curiosity is shown in the personalities and antecedents of the newcomers. These, in the case of the I.M.E.A. Convention, are mainly aldermen and councillors, for once a municipal electrical engineer always a municipal electrical engineer, except in the few cases where he returns, as have Mr. C. H. Wordingham and Mr. J. E. Edgcombe on this occasion, in the honourable position of honorary member, or receives promotion from an assistantship like Mr. R. B. Mitchell or Mr. Nicholls, of York. The councillor "new boys" this time contain a large sprinkling of the Labour element. This is all to the good. If these gentlemen attend the meetings, both formal and informal, as learners, which they seem inclined to do, they will gain a closer knowledge of what electricity supply means and what electricity supply can do to further in a legitimate way the ideals upon which they build much of their policy. It is pleasant to note that their opinions as expressed in convention have been almost universally sane and temperate, and their influence on municipal electrical development should therefore be all to the good.

Wolverhampton, as a town, has many pleasing features, but one of them is not a sufficiently large hotel accommodation to deal with the load that the I.M.E.A. affords. While, therefore, the Council, the Press, and a number of the more distinguished guests are living in the town, of the rest the majority are mainly staying in Birmingham and others are scattered around in Dudley, Stafford, Coventry and Nuneaton. This is a real disadvantage, in spite of the fact that opportunity will be given during the convention for much of that social intermixture and many of those informal meetings which make for the success of these gatherings. The time has, however, come when precedent must be broken and the conventions be held only in towns which can easily accommodate those attending, preferably under one roof.

Tuesday, June 20.

The meeting to-day was held in Wolverhampton. Those staying in that town were therefore able to make a leisurely breakfast before it was time to go to the Grand Theatre. Shortly before 10 o'clock, however, when the Birmingham contingent arrived by chars-a-bancs, there was a large crowd in the foyer, and by the time the MAYOR OF WOLVERHAMPTON (Councillor James Thompson, J.P.) rose to give the convention his official blessing the dress circle was well filled and the front rows of the stalls were occupied, if not crowded. It is becoming customary for the convention meetings to be held in theatres with the council grouped artistically on the stage in front of a drop scene, and it would be interesting to trace the connection, if any, between theatricalism and municipal electricity. The arrangement has the disadvantage, however, that the audience is scattered and that speakers in the discussion, to be heard, must ascend to the stage by devious ways, thus causing some delay and heightening the discomforts of those who incline to nervousness.

A Municipal Welcome.

The MAYOR, in welcoming the Association to Wolverhampton, tuned his remarks to history and archæology rather than to electricity, beginning with the Danes and ending with Prince Albert, via Charles II. and other celebrated and less celebrated persons. Amongst the industries which had in recent years come to the district he mentioned the motor trade and (with natural modesty) boiler making. Wolverhampton, though perhaps not beautiful in itself, was blessed in its surroundings, and it was possible to stay for a fortnight in the town and visit a fresh beauty spot every day. Turning to other matters, he paid a tribute to the foresight and energy of Mr. Allen, and said that if he made as good a president as he did a borough electrical engineer the Association were lucky. (A sentiment which the meeting cordially endorsed.) The electrical industry was the most wonderful and at the moment the most prosperous industry in the country, and without associations like the I.M.E.A. the improvements that must be made in it could not be effected.

The PRESIDENT (Mr. S. T. Allen, Wolverhampton) briefly replied, and then proceeded to deliver his Presidential Address which we give in abstract below.

Mr. S. T. Allen's Presidential Address.

The unfortunate economic position which has arisen as an aftermath of the Great War is by far the most important factor affecting not only the prosperity of the electricity supply industry, but almost all of our national industries. The whole country is struggling against long odds, on the one hand, to adjust itself to the conditions prevailing at the present time, and, on the other hand, to bring about such changes in those conditions as will make for the stabilising of industry, full employment of all classes on productive operations, and a reduction of the financial burdens under which we have been suffering.

Need for an Adjustment of Outlook.

In connection with the supply industry it has been necessary to adjust our outlook, tariffs and operations to the condition of things existing at the moment. It is, however, dangerous and wrong for us to continue to remain satisfied with doing this, hoping that conditions will improve without effort on our part. Each section of industry by its action or inaction affects the destinies of other sections. The electricity supply industry is indissociably wrapped up with other great industries, such as, for example, the manufacturing undertakings dealing with plant and apparatus. They in their turn affect the operations, prosperity or otherwise of innumerable other engineering and allied industries. It is towards the development and progress of the electricity supply industry our special attention must be given at the present time, in order that we do our share in creating that impetus which will hasten the increase of production and sales of commodities manufactured, thus reducing the unemployment and the many doles which must now be made to maintain the country in its unfortunate position.

To bring this about we must first of all fully realise that all those engaged in trade and industry in this country have important common interests, that the success of the electricity supply industry is dependent upon the success of other trades and industries, and without those other industries being kept in a healthy condition the electricity supply industry cannot succeed. To help to promote the common interests, therefore, is to assist our individual interests.

Electricity Supply a Social Organism.

It must be remembered that the electricity supply industry is a part of the social organism. Directly we realise that electricity supply is a national service, we also realise the opportunity of establishing between contending parties within the industry that confidence the absence of which may have been the cause of troubles and delays in the past. The individual interests are only a part of wider interests, the promotion of which should benefit the individual. It is for the I.M.E.A., therefore, to progress with the right driving force behind it, to endeavour to see to it that all industrial concerns are fully educated to the methods, by the adoption of electricity, of cheapening and improving industrial operations in their many phases.

Electrical Co-operation.

The day has gone by when anyone can argue that each municipality in its various operations can quite well act on its own behalf, without regard to or the necessity of co-operating with other local authorities through associations like the I.M.E.A. Just as co-operative associations are necessary and in operation in connection with the supply companies, commercial, technical, employer and employee bodies, so is the I.M.E.A. a necessary body continually to look after and safeguard the interests of local authority undertakings. Joint action does often bring about what individual action fails to, and the results of joint counsels are far more fruitful of success than heterogeneous collections of views made by individuals without regard to the views of others. On account of its very association the I.M.E.A. is asked and expects to be represented on joint committees with other bodies, and in this direction alone is doing very good work which could not otherwise be accomplished.

The Importance of the Personal Element.

It must be remembered that the Association cannot function at all until after efforts have been made by the representatives of which it is composed. Individual authorities, committees and managers of undertakings have, therefore, their peculiar responsibilities at this critical period. One of the most important factors which has special bearing upon successful operation is the personal element. This factor covers the correct attributes of members of committees and responsible officers, a full sense of responsibility, justice, fairness and truth, a keen intention of framing sound policies which will bear sound and fair criticism, an enthusiastic endeavour to bring about the best results even at personal inconvenience, and perhaps at times in the face of small-minded destructive criticism.

No Need for Pessimism.

There is still a tendency for committees to be dissuaded from a sound progressive policy, under the mistaken idea that expenditure for whatever purpose should, at the present time, be curtailed. This is often due to the fact that little distinction is made between the operations of the non-trading and rate-financed sections of a municipality and the electricity department, which as a trading concern, should be conducted on commercial lines. It is also asserted at times that the difficulty of finding the necessary money is a reason for withholding expenditure on such developments which would in normal times be agreed upon. Money can be obtained by municipalities more easily for electricity supply development than by any other bodies. The electricity undertaking of a local authority, when it has been developed on sound business lines, is one of the best assets which that authority possesses.

Having regard to enormous potential loads in towns and in their neighbourhoods, the great advancement which is being made in the application of electricity for industrial, business and private purposes, and the growing demands which are being made for supplies, no municipality having rights to supply electricity should hesitate to develop its undertaking on broad lines. As nowadays, more so than in the past, every town in itself may be considered a large commercial undertaking, competing with other towns, those municipalities who neglect to realise the importance of electricity supply development on the right lines will suffer in the great competition which is ahead of us.

Development Must Precede Demand.

It is of little use for municipalities to say that they will develop their undertakings after demands have arisen. They must create the demands by seeing to it that they have ample electricity supplies ready and available in anticipation of requirements. Successful development does not come by itself, but only follows continued and increasing effort and outlay of money. Expenditure on administration, organisation and publicity must necessarily increase with increased turnover. It is quite useless to expect an undertaking which has reached successfully a certain stage in development to go on increasing its revenues without increasing the amount spent upon administration, publicity, etc. The guide should be mainly the return made per pound of money spent per annum.

Money Necessary for Development.

If close inquiry were made as to why some undertakings have remained almost stationary as far as, for instance, the development of domestic load is concerned, while others have gone ahead so successfully, it would be found due to the hesitation of those particular authorities to expend sufficient to develop the necessary business and the failure to realise that it is as necessary to apply the usual business principles to an electricity supply concern as it is in any other progressive business concern.

During the last twelve months, owing to strikes and industrial troubles, and to the international economic position, many undertakings have suffered considerably from the reduction of output which has naturally resulted in an increase in the cost of production per unit in respect of the capital and other standing charges. These reductions, we hope, will be of a temporary character.

The gaps made in the output curves due to these causes may well be more than made up when normal trade conditions are resumed and after the encouragement of the more extended uses of electricity in the many directions which the public are daily more and more realising make for more efficient operations, the saving of labour and money, and the adding to the comforts and health of the community. Increased output in almost every case means cheaper production costs, and also in itself means more electrical plant and apparatus being sold and thus cheaper apparatus. Cheaper supplies lead to yet greater increased demands and more installations being wired and equipped. Thus the cycle of effects of increased output of electricity is very far-reaching, and tends to increase the prosperity, health and good condition of our towns and improve the industrial condition throughout the country.

What the Use of Electricity Means.

It has been clearly shown also that increased use of electricity proves a great national blessing, in that it means conservation of our coal supplies either for our own future use or for our export trade. The country has, during the last few years, been critically examining the existing methods of generation of electricity, and has found that great improvements can be made in many directions. It has recognised that individual generation of electricity was natural enough, and the only practical procedure, as long as its use was comparatively small, but that as electricity is now a commodity of such everyday use and with such a large and general growing demand, to adhere to the original practice would in many cases bespeak obsolescence.

It has realised the great necessity of generation on a much larger scale, and to provide for greater areas, and, on that account, the necessity of joint action of various supply authorities in the different districts in connection with generation and main transmission, and has shown its decisions in legislation towards those ends. So far the divergent interests of various individual authorities have not permitted the establishment of constructive policies satisfactory to groups acting together, but now that it is realised that joint action for the generation portion of their operations can be made without prejudicing the rights or stability of their individual undertakings, and that by such joint action they can reduce the cost of supplying themselves, approved schemes for joint working will soon come into satisfactory operation in many districts throughout the country.

The Public's Support.

The public, seeing its interests properly safeguarded, can be counted on for sympathetic support towards the schemes, while industrial interests in general, being in the business of manufacturing commodities rather than electrical energy, will find it natural to favour any action that will facilitate a cheaper supply of energy which is an accessory to their operations. The outcome of the establishment of properly co-ordinated and balanced schemes for the establishment of joint generation with common and general main transmission lines will be the tendency to equalise industrial opportunity, and I consider that we can look towards the future in the most optimistic spirit.

In proposing a vote of thanks to the President for his address, Councillor J. G. Beaumont (St. Marylebone) said that the remark that "each section of the industry by its action or inaction affects the destinies of each other section," approached the dignity of an aphorism. Mr. Allen's arguments, put forward in short sentences, fell like hammers on their brains and stimulated them to take in ideas to which they had hitherto remained insensitive.

The President then called on Lieut.-Col. W. A. Vignoles, D.S.O. (Grimsby), to read his Paper on "The Extension of the Uses of Electricity for Domestic Purposes." This we give in abstract below.

The Extension of the Use of Electricity for Domestic Purposes.

By LT.-COL. W. A. VIGNOLES, D.S.O., Borough Electrical Engineer, Grimsby.

The subject of this paper is of great importance at the present time. Though the worst period of high prices has passed, many undertakings are left with the burden of large capital expenditure on buildings, plant and mains, at prices much above those ruling to-day. This expenditure should be written down out of revenue. Meantime the reduction in load factor on shop-lighting, due to early closing and summer-time and the falling off in the power load owing to the slump of trade, make it necessary to look for revenue in other directions. In the domestic field the largest consumers are already connected. The demand comes from the smaller houses, which are apt to prove unremunerative. The paper is accordingly devoted to the questions: (1) Is a substantial increase in domestic load obtainable on a remunerative tariff? and (2) how can such business be obtained?

The Value of the Domestic Load.

The value of any load is approximately represented by the load factor. In the original paper the author presents typical

figures for the 1922 and pre-war hours per annum for various classes of consumers in the Grimsby district. Hours per annum for offices (both lighting and heating) are the same as in pre-war days—viz., 175 to 200 for lighting, and 900 for heating. For shop lighting there has been a diminution from 600 to 800 to 450 to 650. Theatres and cinemas, as in pre-war days, are credited with 1 200. The industrial load is put at 2 360, as compared with 2 710 for power, and 250, as compared with 400 for lighting. Domestic lighting shows a fall, 1 450 to 1 250, but domestic heating and cooking, at 2 500 and 3 250 respectively, are unaltered. The actual hours of maximum demand will, of course, be less. With heating a new form of peak—the "cold-snap" peak—has to be considered. With cooking there is no "cold-snap" peak, and the heaviest load occurs on Sunday mornings, when the power load is a minimum. Moreover, the demand in summer should be higher than in winter, when some coal fires are used. On weekdays the heaviest load will probably be about midday. This is, therefore, a very useful load. The same applies to thermal storage (electricity being used to heat water during "off-peak" hours). Experimental work in this direction has been done on the Continent, and should be closely watched.

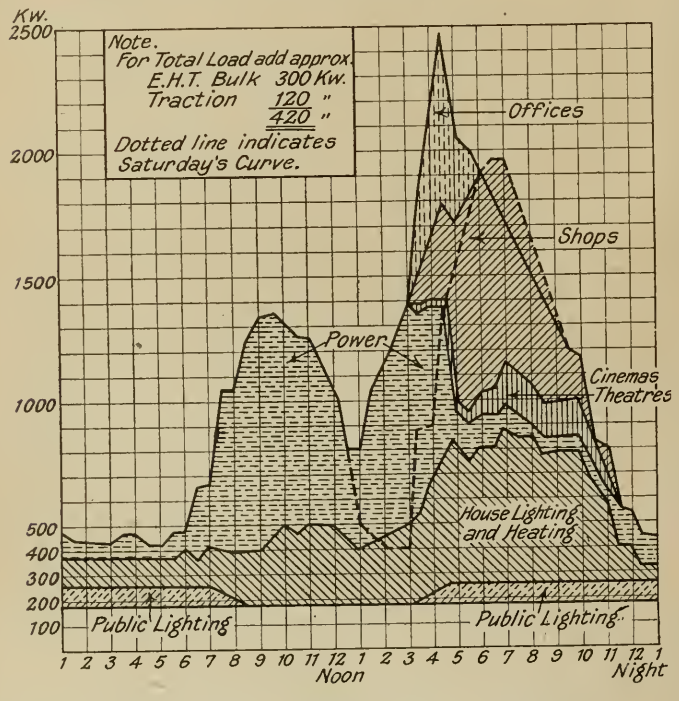

Fig. 1.—Load Curves. Grimsby, Friday, December 16, 1921.

Generally speaking, while a heating demand is desirable, there are certain difficulties that must be watched. The supply for cooking and auxiliaries, such as irons, washers, etc., is still more desirable, and does not have the drawbacks that may occur with a purely heating load.

The Cost of Supply.

Cost can be divided into: (*a*) Consumer cost—i.e., expenses due to dealing with additional consumers; (*b*) standing charges, proportionate to consumer's maximum demand; (*c*) running costs, proportionate to units consumed. In order to illustrate how average cost per unit varies with number of hours of use, curves for Grimsby and Wolverhampton are presented (see Figs. 1 and 2). In Grimsby the present cost of supplying a consumer with a maximum demand of 1 kW (coal 20s. per ton) is based on the formula: £2 per annum per consumer, *plus* £20 per annum per kW of maximum demand, *plus* 0·75d. per unit sold. In Wolverhampton the corresponding formula is £15 1s. per annum per kW of maximum demand, *plus* 0·423d. per unit sold. Thus in Grimsby the average cost of supplying a shop taking 450 units per annum per kW of maximum demand is about 1s. per unit, as compared with a charge of 10d. In Wolverhampton the corresponding cost is 8½d., the charge being 8d. At present many consumers are probably supplied at a loss by undertakings, on a flat rate of 8d. or even 10d.

The Problem of the Small Consumer.

The problem of supplying small consumers is an acute one, as the number tends to continually increase. Large consumers, especially if they purchase plant at very low post-boom prices, may be able to compete with the undertaking.

To show the size of domestic load where a suitable charge is made for heating and cooking the following figures for five different towns are presented, assuming no gas is used and heating and cooking are done electrically:—

1. 2 000 to 2 500 units per annum per house (140 for lighting).
2. 2 000 to 2 800 units per annum per house.
3. Six times the lighting consumption.
4. 1 300 units per annum per house (housing area).
5. Ten times the lighting consumption.

In one town with a tariff of 2½d. per unit, and no special effort made to develop heating load, 35 000 out of 2 900 000 units were sold for heating to 700 consumers. A heating load builds up rapidly under a suitable tariff. Thus in Norwich 1 500 000 units were sold in 1921 at 2d. to 1½d. in Glasgow 6 859 000 units. In Marylebone 2 000 000 units were sold on a flat rate for heating and cooking, and 7 000 000 on a multipart tariff for light, heat and cooking. Norwich had over 5 000 kW of cooking and heating appliances connected at the end of 1921, Glasgow 26 907. Assuming the domestic consumer would use 1 500 to 2 000 units per house per annum, sales would be 15 to 20 million units per annum if only half the houses were supplied on this basis in a town with a resident population of 100 000 in 20 000 houses.

Essentials of Domestic Load.

The essentials in developing a heating and cooking load are: (*a*) the price for electricity must bear comparison with the cost of coal or gas; (*b*) apparatus must not be too expensive, and must give little trouble. It is useless to go in for publicity unless the undertaking can "deliver the goods," and no amount of publicity can replace the skilled canvasser or demonstrator.

Tariffs.

A two-part tariff is the only fair way of charging for electricity for all purposes; but at present an alternative flat-rate must be offered (except in Grimsby, where special powers have been obtained). This flat-rate should be the maximum price authorised. All reductions should be in the form of a two-part tariff. Prices must, naturally, be fixed with due regard to the local cost of gas or coal. For cooking and heating a flat-rate of 2½d. might be fixed. The alternative two-part tariff should involve: (*a*) a fixed first sum per consumer; and (*b*) a charge per kW of maximum demand, or its equivalent. The running charge part of the tariff should not exceed 1½d. per unit, and is less in some towns. In Grimsby the tariff has been fixed at £2 per annum per consumer, £20 per annum per kW of maximum demand, and 1½d. per unit. For private houses the first charge will be £20, *plus* 20 per cent. of the rateable valuable of the premises. For other premises the maximum demand charge is calculated on the estimated maximum demand for lighting, based on an inspection of the premises, with an addition of £1 per kW of the heating or cooking load during "peak" hours.

Under the Grimsby Corporation Act of 1921 it is not compulsory to offer a flat-rate. But at present a flat-rate of 10d. for lighting and 2½d. for heating is being retained until some experience has been gained of the two-part tariff, which it is hoped will be voluntarily adopted by most consumers.

Cost of Extra Heating and Cooking.

The cost of supplying additional heating or cooking load, allowing for "thickening" the mains and feeders, is estimated at £4 10s. per kW of maximum demand, and 0·75d. per unit sold (with coal at 20s. per ton). The average costs for office heating, domestic heating and domestic cooking, work out to 1·9d., 1·3d. and 1·1d. respectively. A flat rate of 1½d. will cover the cost except in the case of offices, where the addition of a charge per kW is specially necessary. The profit on the supply for cooking should be substantial.

The tariff should be framed with an eye to competition. So far as lighting is concerned it is not necessary to cut prices finely. For other purposes we may adopt the ratio: Price of gas per therm to price of electricity per unit for heating and cooking should not be less than 6·5. Thus with gas at 10d. per therm a fair competitive price for electricity would be 1½d. per unit.

The Attitude of the Supply Engineer to the Domestic Problem.

The author recalls two meetings held about 1913 or 1914, one at the Institution, the other at an I.M.E.A. Convention, where domestic electrification was discussed. Evidently but a very small proportion of those present used electricity in

their own houses for heating, and fewer still for cooking. If a supply engineer believes in the domestic load, he should first introduce a suitable tariff. He should then train his staff and interest the electrical contractors in the town. The British Electrical Development Association is prepared to launch a campaign, but they must have the sympathetic support of the supply engineer and the contractor.

Adequate and Reliable Apparatus.

The provision of adequate and reliable apparatus is naturally important. There has been much progress during recent years, and the cost of maintenance is not now excessive, even if apparatus is handled by servants. However, elements do fail at times, and apparatus should be so designed that they can be readily replaced by an unskilled man. The supply undertaking should be prepared to do this work on receipt of a telephone message. If apparatus is hired out, maintenance must be included in the charge for hire and periodical calls made to see that it is working satisfactorily. Lady inspectors could do this work well.

Hire of Apparatus.

So far the cost of apparatus has been high, a complete cooker with oven, grill and hot plates being listed at £18 to £22. Such high prices are apparently due to small output, and undertakings should combine to purchase in bulk. Standard types should be evolved for hiring. With a suitable demand, the price of an electric cooker should not exceed £10 to £12. On the basis of a seven years' life, this might be hired out at £3 or £4 per annum, including maintenance. It is not necessary to hire out radiators which are obtainable at reasonable prices; the same applies to light articles such as toasters or flat-irons. Generally speaking, the rent should cover all expenses, unless there are special inducements to a lower rental in the form of anticipated revenue from the sale of electricity.

The following table, taken from an article by Mr. W. F. T. Pinkney * is interesting as showing both the rentals quoted in Newcastle and the units per annum estimated for each piece of apparatus: —

Apparatus.	Net cost.	Retail price.	Average Maintenance cost per annum	Rental per annum.	Approximate units sold per item per annum.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	
Iron	12 8	1 1 0	1 0	6 0	35
Kettle (2-pt.)..	16 0	1 10 0	2 8	8 0	50
Kettle (3-pt.)..	1 10 0	2 10 0	2 8	10 0	70
Fires	1 10 0	2 12 6	2 7	12 0	500/1 000
Cookers ..	12 10 0	22 0 0	1 0 0	1 10 0	1 600
Cookers ..	16 0 0	25 0 0	1 0 0	2 0 0	1 750

Conclusions.

To sum up the arguments in this paper :—

(*a*) The domestic load may rise to enormous figures if properly encouraged.

(*b*) A price not exceeding 1½d. per unit for heating and cooking is a satisfactory figure from the consumer's point of view, under present conditions.

(*c*) At this price there is some danger of heavy peak loads developing due to office heating, but supply for cooking at this price will show a substantial profit.

(*d*) A hire scheme is essential to the development of a cooking load.

(*e*) Apparatus should be let on hire at rentals calculated to cover all expenses, except perhaps in the case of ovens and complete cookers where, owing to the high cost of the appliances, some help is required from the profits from the sale of electricity.

(*f*) Maintenance of apparatus on hire must be included in the rent.

(*g*) The department must keep in touch with cooking consumers by periodical calls of some member of their staff.

(*h*) Every member of the staff of an electricity department (and everyone connected with the electricity industry) should live in an "All-Electric" house.

The Results of a Vigorous Policy.

A vigorous policy on the above lines by undertakings in the country would have a remarkable effect on the future of domestic supplies. The increased demand for apparatus would have a marked effect on the first cost, while maintenance charges would be reduced with proper organisation; the effect, too, on the consumer would be cumulative, and the "Second Hundred Thousand" electric cookers would be far easier to place than the first.

* The Electrician, March 31, 1922, p. 371.

The Electrical Papers frequently compare electrical progress in the United States with that in Great Britain, to the disadvantage of the latter. The Electrician, in the issue of March 31, 1922, stated that of the houses wired in the United States 36 per cent. use electric washers, 40 per cent. use electric vacuum cleaners, 2 per cent. use electric dish washers, 71 per cent use electric irons, 2 per cent use electric cookers.

Though no figures are available, the writer is of opinion that Great Britain is not behind as regards the last two items, which are the important ones from the point of view of current consumption, and that there is no reason why we should not lead in electric cooking.

The convention of 1913 saw the formation of the Electrical Vehicle Committee, which has been of material assistance in

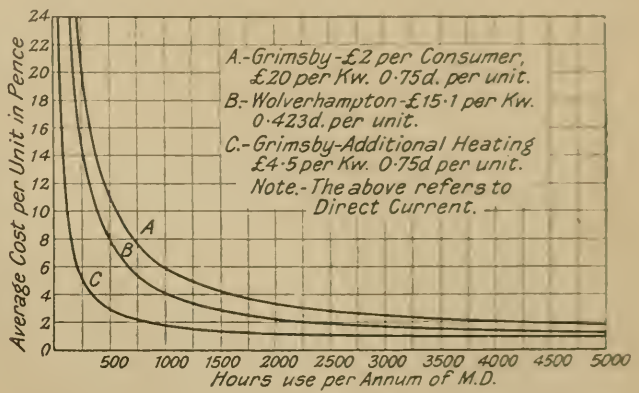

Fig. 2.—Average Cost per unit in Relation to Hours use per Annum of M.V.

developing the electric vehicle, to the great advantage of many undertakings. The Convention of 1914 saw the inauguration of the Development Committee, from which sprang the vigorous British Electrical Development Association, an organisation which is doing valuable work for electrical industry. The wish of the writer is that the Convention of 1922 may see a number of towns combine together to introduce hiring schemes for cookers, and generally to develop the supply of electricity for domestic purposes.

DISCUSSION.

Mr. R. B. Mitchell (Glasgow), who made his first appearance at an I.M.E.A. Convention, agreed that it was desirable to encourage the domestic load. The cooker must first be encouraged, for every cooker connected could be depended upon to consume 1 500 units per annum. But cookers must be hired. They must also be accompanied by an electric kettle to overcome the criticism of the hot plate. It was of no use hiring out small appliances, but it might pay an undertaking to give current consuming devices free. In Glasgow the "snap peak" load had amounted to between 8 000 and 10 000 kW, but the great point about it was that it usually came in the morning, and need not be feared unless the plant was too small for the load. At May 31, 1922, they had 30 489 kW of domestic load connected, the charge being 12½ per cent. of the rental, plus ½d. per unit.

The Curves—Fact or Imagination.

Mr. L. L. Robinson (Hackney) asked how the author arrived at the analysed load curve in the Paper which gave the curves for the individual portions of the supply. It was enormously useful if accurate, but he suspected that many of the curves depended largely on the imagination. They had all experienced the "snap peak," but it was nothing to be afraid of, and could be dealt with by their normal reserve plant, especially if some of the boilers were oil-fired. Flat rates should be kept high, and consumers rewarded in accordance with their deserts by means of multi-part tariffs. In the past they had made too much of the power load. They must now endeavour to develop a well mixed load so that when one sort slumped another would boom. Apparatus must be hired at rates which met interest, capital charges and maintenance, but no more. He was about to experiment with free installations and charging a slightly higher price, through prepayment meters, for the electricity supplied. For developing the domestic load an enthusiastic and a competent sales department was necessary. Even now if electricity were supplied below 1½d. anybody who cooked by gas had money to throw away. His department included a 3-pint kettle with each cooker, but he would not like it to go out that the electric hot plate was inefficient. It was a most efficient piece of apparatus on a cooker for its own work.

Conditions in Marylebone.

Ald. J. A. G. Beaumont (Marylebone) said the rateable value tariff might be ideal on paper, but it would be impossible to apply it in Marylebone, where the rateable value of similar houses varied

according to the uses to which the houses were put. Results in Marylebone seemed to show that their progress with heating and cooking, and to a small extent with power, had been decidedly profitable with the low figure of 1¼d. flat rate. Hot plates and radiator elements should be so designed that they could be replaced by any user in the same way as a lamp. In Marylebone they preferred to let rather than sell heaters, as it kept the undertaking in touch with the users and the apparatus in proper working order. Buying in bulk, which the author had suggested, was worth consideration. His undertaking has been supplying free heaters and cookers for some time and adding ¼d. to the unit charge. He agreed that the staffs should have "all-electric" houses, but they could not be expected to do it unless they got a favourable tariff.

Mr. C. W. Charlesworth (Wolverhampton) said the most important question awaiting solution in every industry was over-capitalisation. To deal with this, rate relief and rate aid were both unsound, and the only way to effect the writing down was from revenue, which meant maintaining prices beyond the immediately necessary level until the required surplus was obtained. Whether this was possible at present, having regard to the grave difficulties in the way of reducing prices to keep pace with the reduction of wages and certain other items seemed problematical. He felt that the most fruitful method was to increase the output.

The Hopkinson System the Only Logical Basis.

Mr. C. H. Wordingham said that in all towns the domestic load was of considerable importance, and particularly in those towns which were mainly residential. Getting the domestic load, however, depended entirely on a suitable tariff. The Hopkinson system was the logical basis to which we would ultimately come for domestic as for power purposes. A large number of different scales of charge were to be deprecated. The greatest want at present in connection with tariffs was a cheap reliable demand indicator, for it was essential to work out the maximum demand, and not to play with rateable values and other absurd things which had nothing to do with the demand, while the ridiculous flat rate should be abolished. If the consumer could be properly educated in demand dodging so that he used most of his appliances off the lighting peak he would obtain electricity practically for a penny per unit, and he ventured to think the scope for domestic appliances was a wide one at that rate.

Councillor A. Sinclair (Swansea) did not agree with the author that the small lighting consumers might easily become a source of loss. His experience showed the contrary.

Fertilising the Field.

Mr. E. E. Hoadley (Maidstone) said what they had heard during that discussion concerned the filling up of the load curves from six in the morning till midnight. They had heard little of what should be done to help the same curves between midnight and six in the morning. At Maidstone they had a load of 3 000 kW, of which 50 per cent. was a night load. But that left a big valley to fill. He hoped the problem of thermal storage and the supply of hot water by electrical means for domestic uses would be well explored within the next year or two. He would like to impress on members the necessity of prompt and efficient service in regard to repair of hired cookers. A flat iron was the most satisfactory electrically heated article that could be put into a household, and after using it a month or so the feminine mind was in a nice condition to receive information about electric cooking.

South African Experiences.

Mr. E. Poole (Durban) said since the introduction of a low tariff in Durban the output had enormously increased. A low tariff, he believed, would bring about such a demand for apparatus that manufacturers would soon turn out something not too expensive or troublesome. The consumption per consumer had been practically doubled, and out of 8 million units sold for lighting and cooking one half was entirely for cooking.

More Ways of Using Electricity.

Mr. J. W. Beauchamp said Col. Vignoles had shown that the conditions were complicated by short hour demands for lighting and power. But there were things which could be done that had not yet been done. The later lighting of shop windows was one. The cheapness of electrical cooking depended on the price of gas; 1½d. per unit against 5s. for gas was a favourable figure. If they did not get hundreds of cookers on that it would be because they were not pushing the business. A fire load unaccompanied by cooking was not altogether a blessing, particularly in a city area. Mr. Allen had on view in Wolverhampton a heat accumulation stove. He (Mr. Beauchamp) had put it there because he wanted the members to think about that problem. Nitrates afforded a means of taking supply when it suited the supplier to give it and when it suited the buyer to receive it. No change of the kind would come about quickly, but it was one of those new things to which they should give attention. It was well known that there were thermal storage water heaters. He had bothered with this stove because they had little apparatus for warming air or rooms. Members might know Harrison and Beard's heat accumulation stove. It warmed the air, using the latent heat of acetate of soda. They should get busy thinking about filling those hollows in the curves by means of heat accumulation. If they took the heat in the night they would get it for 2d. or something of that nature. The small water heater introduced by Mr. Russell of Shoreditch was a useful adjunct for cookery, and took a lot of duty off the hot plate. If they were going to get half the heat in each of the homes in large cities like Wolverhampton a great deal of it would have to be delivered on the storage system.

Mr. A. H. Shaw (Ilford) said, on his multi-part tariff he had different rates for summer and winter, because the power load was only small and he had a heavier load during the winter and a very light one during the summer. This secondary rate was 1½d. in summer and 2d. in winter. The primary rate worked out at 21 per cent. of the rateable value. In Ilford they had 600 small houses connected by services in blocks. Some services supplied 12 houses and others 24. There were small meters in every house, although no meter rent was charged. The results were, on the whole, satisfactory.

Mr. George Wilkinson (Harrogate) deprecated the idea of having a high initial price per unit. Better means could be adopted than introducing a 10d. or 1s. initial rate.

At the conclusion of the meeting those present were conveyed in motor chars-a-bancs to the Royal Artillery Headquarters, where they were entertained to lunch in the Drill Hall by the Wolverhampton Electricity Committee. Our hosts are to be congratulated on having such a fine hall at their disposal, and on the tasteful way in which it was decorated, not only with modern tapestry hangings but with a drop scene reminiscent of the country round Wolverhampton itself. Thanks for the entertainment were suitably presented, in a speech by Councillor Beaumont and musically by the remainder of those present, and were acknowledged by the Mayor.

Then once more chars-a-bancs were requisitioned to take the party to Apley Terrace, on the River Severn. The route taken was *via* Bridgnorth, while on the return Shifnal, the scene of a certain Royal honeymoon, was passed. The grounds and the view were adequately inspected as they deserve to be, and tea was served in the grounds. We heard a certain amount of shop in spite of the sylvan scenery, but, then, engineers are like that.

In the evening a Reception was given by the Mayoress of Wolverhampton at the Art Gallery.

Wednesday, June 21.

This morning members were early astir armed with coats and umbrellas for the journey by road to Stoke-on-Trent. The now familiar chars-a-bancs were under weigh soon after 9 a.m., and a very pleasant run *via* Stafford was the reward of those taking part. On nearing Stoke, the local beauty spot, Trentham Gardens, of which a closer view was given in the afternoon, was passed.

Unfortunately in some ways the organisers of this expedition had been a little too optimistic. The two hours allowed for the journey was barely sufficient for the Wolverhampton party, and nothing like adequate for those coming from Birmingham. The result was the proceedings started nearly an hour late with the briefest of welcomes from the Mayor of Stoke-on-Trent (Ald. S. Sproston) and the President, after an even briefer reply, called on Mr. E. Calvert to read his Paper on "The Administration and Control of Electricity Departments," explaining as he did so that luncheon would be put off for half-an-hour in order that there might be some discussion. We give this Paper in abstract below.

Administration and Control of Electricity Departments.

By EDWARD CALVERT, Chief Electrical Engineer, Finchley.

Municipal accounts have received much consideration in recent years. The Public Health Acts do not contain any detailed method of control of accounts, but deal rather with the form in which district councils' accounts must be kept, provisions for audit and publication, etc. Accounts of receipts and expenditure must, however, be made up "in such a form and to such day in every year as the Local Government Board may appoint." Considerable latitude is allowed to the qualifications of the treasurer, but it is evidently assumed that other officers will handle the money. The Acts did not therefore contemplate a finance department which would deal with the whole finances of a local authority.

The Provision of Independent Checks.

Some doubt exists as to whether the Public Health Acts govern municipal trading undertakings. In 1906 the Local Government Board appointed a Departmental Committee "to inquire and report with regard to the system on which

accounts of local authorities in England and Wales should be kept." Of the witnesses who gave evidence none was directly responsible for the administration of a municipal trading department. The chief feature of the recommendations of the Committee, issued in 1907, is the differentiation of duties of executive officers and departments in such a way that transactions may be checked by independent records of accounts. It is recommended that officers concerned with administration should not control the final accounts thereof; and conversely officers who supervise finance should not take part in the administration or in the receipt and payment of money. The effect of these and other recommendations would be to place in the hands of the Finance Committee powers which might even take away power from the hands of the local authority itself. Much opposition to the recommendations has been raised, and no further action appears to have been taken by the Ministry of Health.

Among the criticisms raised may be mentioned that it would be impracticable for any one committee to deal efficiently with the financial details of all committees; that duplicate books of accounts would be needed; that a single finance officer would not have sufficient technical knowledge to deal with the business of several departments; that a great increase in staff would become necessary; that committees other than the finance committee would become practically sub-committees, leading to inefficiency in view of the absence of a suitably responsible head; that the interpretation of the recommendations would lead to difficulty.

Some Weak Points.

There has been some revival of the movement in favour of these recommendations, and the Council of the I.M.E.A. recently passed a resolution disapproving of the effort to place the general control of electricity departments under any officer other than the chief electrical engineer and general manager. The principle underlying the recommendations is analogous to that in force in the L.C.C. since 1889. From the report of a Special Committee appointed on June 21, 1921, it appears that the L.C.C. is not entirely satisfied with existing procedure. The present highly centralised system is regarded as having drawbacks, including over-elaboration and overlapping, and especially the division of responsibility between heads of executive departments and the head of the accounting or checking department. Accordingly a new scheme is proposed under which the comptroller would act as financial adviser, paymaster-general, and receiver-general and auditor, and would keep the main accounts, but the heads of executive departments would have entire responsibility for all payments for which they are certifying officers, for collection of revenue in their department, and for keeping their departmental accounts. Such a scheme of decentralisation would, it is thought, be quite feasible.

The conclusion confirmed by these considered opinions is that a chief officer cannot efficiently carry out the work of his department unless he is held solely responsible for the financial position.

I.M.E.A. Opinion.

In conclusion, the publication of the following considered opinion of the Council of the Association may be opportune :—

In municipal trading departments which have to be run on business lines, it is imperative that the chief electrical engineer and general manager should bear the full responsibility for the working and development of the undertaking. If the financial control is taken away from him and placed under another officer, a state of dual control is set up and the usual evil results will inevitably follow. The effective check upon the financial details can best be obtained by a properly organised system of audit, and preferably by auditors independent of the permanent staff of the municipality. When the operations of the department in question justify the same, the books should be kept by the staff of the department. A continuous audit is always preferable. In electricity departments questions of commercial management and financial details are so dependent upon technicalities as to render these inseparable; they can only be satisfactorily dealt with by one who has high engineering qualifications for dealing with all branches of the department's business.

DISCUSSION.

Ald. A. Senington (Bristol) said that London could not be taken as typical of the conditions to which the author referred. The demarcation of the duties of officials was important in connection with a trading committee such as an electricity committee, but financial chaos might result if one man, say the electrical engineer, were allowed the sole control.

Mr. F. W. Purse (West Ham) remarked that many insidious attempts were being made by financial officers to obtain the control of electricity undertakings, and the movement was still more dangerous now that the "Geddes" Committees, set up by many of the Councils, were at work. It was true electrical engineers did not want to be troubled with raising money, and the actual keeping of certain accounts was a matter which none of them would differ upon. But when it came to a question of saying whether certain extensions should be made the engineer was the only man who could give information. Therefore, there could not be any question as to what theline of demarcation should be.

Mr. C. H. Wordingham said an engineer who did not have charge of the financial part of his work was a contradiction in terms. He concurred heartily with the Council's resolution. After all, the technics of accountancy were nothing compared with the technics of the scientific side of engineering. It was the man himself who was going to determine whether the undertaking was a success or not. His technical knowledge was merely a box of tools, and the accountancy tool was the simplest and easiest of the lot.

Differences Between Municipal and Company Finance.

Mr. Norman Staniland (Hornsey) said Mr. Calvert had imagined an autocratic finance committee and a very autocratic borough treasurer. It was wrong to compare municipal with company finance, because the way money was spent was quite different. The ordinary council had a united district fund, and the debts were more or less merged in that. At Hornsey all the chairmen of the spending committees were on the Finance Committee, and had their chance to say what they thought about the treatment of their particular committee. He did not see how one could ask for a watertight electricity department when it was dependent on the whole district for any out-balances. The L.C.C. had recently appointed a special control officer to look into the financial standing of all the departments and keep an eye on how they were worked.

Councillor F. Burgess (Bristol) supported co-operation between the two departments.

A Working Arrangement.

Mr. W. C. P. Tapper (Stepney) said with the present methods there was duplication of work. Many records were kept twice over. The engineer must be able to get the information he wanted when he wanted it, and if he had not the books in his department he could not do so. The books should be kept in the department by an officer who was a qualified accountant, under the general manager. The borough treasurer or accountant should carry on a continuous audit of the books of all the departments. The L.C.C. had gone into this question carefully, the committee charged with the work had come to a definite conclusion, and they should follow their lead.

Councillor E. R. Dymond (Hereford) said if two people were responsible for the financial efficiency of the electricity department failure would result. No man trained simply in accountancy and finance could accept the whole responsibility of so technical a work as electricity supply.

Follow the L.C.C.

Ald. C. R. Attlee (Stepney) remarked that the electricity department must not be too widely separated from the others. It was carried on for all the inhabitants and not only for the consumers. If too much power were put into the hands of the technical officer the tendency would be to look after the consumers rather than the ratepayers generally. They should follow the lead of the L.C.C. in the matter.

Mr. J. W. Beauchamp thought they should make the collection of accounts an opportunity for propaganda. This could not be done if they were sent out from the borough treasurer's office.

Mr. L. L. Robinson (Hackney) said in his undertaking there was a liaison officer in the offices of the electricity department who kept it in touch with the finance departments. What was to be done from an engineering or trading point of view was settled by the Electricity Committee and confirmed by the Council with the advice of the engineer. Arrangements were made so that the treasurer could have the greatest possible facilities for a running audit of the electricity department's accounts. The accounts went out from and were paid in their own building, and they obtained the useful result Mr. Beauchamp had referred to.

Bailie W. Crawford (Paisley) said at Paisley the Electricity Committee was a committee of the whole Council, and out of that they formed an advisory committee to co-operate with the manager. They gave the manager freedom with regard to extensions, and also to spend money, with the proviso that his suggestions were put before the advisory committee and afterwards submitted to the Council. The I.M.E.A. should see that all their engineers were well equipped technically, and were also commercial men able to extend their undertakings.

Co-operative Solution.

Councillor A. J. Ward (Sheffield) did not agree with the borough treasurer having control, but in cases where the engineer had more than he could do, a qualified commercial man should be appointed to relieve him of some of the duties.

Mr. CALVERT, in reply, said his view was that in every municipality there should be co-operation between the principal officers of the various departments. Municipalities, in appointing an engineer to manage a large trading department, did not sufficiently carefully assure themselves that his qualifications included other things than ordinary mechanics. The municipality was then at fault, and not the engineer. The engineer, so-called, was nowadays the general commercial manager with a sound knowledge of engineering thrown in, and, as such, he should be presumably in a position to employ engineering brains to carry out the more detailed work.

At the conclusion of the meeting those attending were entertained to luncheon by the Stoke-on-Trent Electricity Committee, and subsequently divided into parties which visited various engineering and pottery works in the district. These parties co-ordinated again at Trentham Gardens, where tea was served, and the return was made by road to Wolverhampton and Birmingham. In the evening, somewhat mercifully, we were left to our own devices, and a Wild West drama at the local picture house tintillated the intellects of some.

Thursday, June 22.

This morning the Convention journeyed to the Witton works of the General Electric Co. where the meeting was held in the Main Hall of the Magnet Club. The Wolverhampton party this time had a taste of Black Country scenery in cold weather and were quite ready to enjoy the warm welcome which this unofficial hostelry knows so well how to provide. Unfortunately all this sort of thing made the meeting very late starting and a strangulated discussion fought for existence between club amenities and the attractions of Witton works.

The subject was "Sub-station Equipment, including Automatic Control," a Paper on this subject, of which we give an abstract below, being read by Mr. R. A. Chattock.

Sub-Station Equipment, including Automatic Control.

By R. A. CHATTOCK, City Electrical Engineer, Birmingham.

The equipment of modern sub-stations involves the consideration of several types of transforming apparatus and switchgear. In this paper it is proposed to deal with :— (1) the various types of sub-station plant available ; (2) the application of these types to various classes of supply ; (3) the conditions under which automatic operation is beneficial, and the methods of obtaining it ; (4) typical sub-station lay-outs, buildings, plant and switchgear, and results obtained under working conditions.

Types of Sub-Station Plant.

The various types of sub-station plant available are dealt with briefly, assuming an incoming supply of 11 000 V three phase alternating current : an outgoing supply of 500 V d.c., for power and lighting purposes, with a regulation of ± 5 per cent. or 1 500 V d.c. for railway traction purposes : a speed of 500 revs. per min.

Supply engineers are familiar with the details of such machines. It is only necessary to tabulate their characteristics for reference as follows :—

The Rotary Converter.

The efficiency of a 1 000 kW rotary converter equipment supplying d.c. at 500 V at 25 cycles varies from 92 per cent. at half load to 94 per cent. at full load, and from 91·4 per cent. at half load to 94 per cent. at full load at 50 cycles. When a d.c. voltage of 1 500 is required—*e.g.*, for railway traction—the efficiency varies from 92·8 per cent. at half-load to 94·5 per cent. at full load. In this case it is necessary to run two 500 kW sets in series in order to obtain 1 000 kW. The efficiencies of such a combination vary between 91·1 per cent. at half-load and 93·5 per cent. at full load.

Another advantage of the rotary converter is high power factor which can be kept either at unity or with a leading characteristic—a great advantage on systems carrying a large inductive load.

The present-day costs of rotary converter equipments of 1 000 kW capacity vary from £6·10 to £7·37 per kW.

The La Cour Motor Converter.

This machine is not quite so efficient as the rotary converter, and is only advocated for 40 cycles or over.

Rotary converters now run satisfactorily even at 50 cycles, so that the need of the La Cour converter is disappearing. For the higher d.c. voltages required for railway traction work, it will, however, enter the field, as it is possible to construct 1 000 kW machines supplying d.c. at 1 500V, thus avoiding the necessity for running two in series as is the case with 50 cycle rotary converters. The efficiency of a La Cour converter varies from 90 per cent. at half-load to 92 per cent. at full load. The power factor can be adjusted to unity. The cost per kW at present-day prices amounts to £4·87.

The Synchronous Motor Generator.

The efficiency of a synchronous motor generator varies from 85·8 per cent. at half-load to 89·5 per cent. at full load. There is no distinction in machines built for 25 and 50 cycles. Special starting motors are required for starting and running up to synchronism. The power factor can be kept at unity, or given a leading characteristic if desired, by varying the excitation, without affecting the stability.

The cost at present-day prices is £6·89 per kW for 25 cycles and £6·5 per kW for 50 cycles.

The Induction Motor Generator.

The efficiency of the induction motor generator is slightly higher when run on 25 cycles than when run on 50 cycles, and varies from 85·5 per cent. at half-load to 88·8 per cent. at full load.

The power factor cannot be adjusted, and varies from 84 per cent. lagging at half-load to 90·5 per cent. lagging at full load when running on 25 cycles, and 74·5 per cent. lagging at half-load to 85·5 per cent. lagging at full load when running on 50 cycles.

The cost at present-day prices is £5·84 per kW for 25 cycles and £5·56 per kW for 50 cycles.

The Synchronous Induction Motor Generator.

The efficiency of the synchronous induction motor generator is lower than that of the ordinary induction motor generator, but the power factor can be adjusted to unity at full load, and with constant excitation it has a leading characteristic at lower loads. This may be a valuable consideration. If the excitation is varied to keep the power factor at unity the machine tends to become unstable at low loads.

The cost at present-day prices is £6·40 per kW for 25 cycle plant, £6·18 per kW for 50 cycle plant.

The Mercury Arc Rectifier.

The mercury arc rectifier has only recently been made commercially in large sizes. The efficiency depends upon a constant loss in maintaining the arc in the rectifier cylinder. Accordingly, as the d.c. voltage is increased, so the efficiency improves, and may attain 92·5 per cent. at full load (on 500 V d.c. 50 cycles), 91·2 per cent. at full load when run on 25 cycles. 95·8 per cent. efficiency is attainable for 1 500 V d.c. at full load on 50 cycles with a 825 kW rectifier.

For a 1 500 V d.c. supply this apparatus is therefore more efficient than any type of rotary apparatus on the market ; on 3 000 V the difference is still more marked. The power factor of this apparatus remains practically constant at all loads. The cost at present-day prices is :—

Two Cylinder—1 000 kW, 500 V, 25 Cycle	..	£8·76 per kW
1 000 kW, 500 V, 50 Cycle	..	£7·48 per kW
Single Cylinder—825 kW, 1 500 V, 25 Cycle	..	£6·38 per kW
825 kW, 1 500 V, 50 Cycle	..	£5·04 per kW

The Storage Battery.

The storage battery is a valuable adjunct to the d.c. sub-station. Its efficiency regarded as a unit with its charging boosters and its necessity for drawing transformed energy from the a.c. system is about 63 per cent. When the cost of the current passed through the battery is taken into account, a higher economic efficiency results. The battery, being charged at night, can be supplied at the cost of coal only ; at times of emergency the supply returned to the line is practically priceless, and at times of peak load the value is a maximum. Taking the two hour rate of discharge as a measure of capacity, and including the cost of regulating switch and charging booster, the cost per kW at present-day prices is £35.

The Static Transformer.

The efficiency of this apparatus is very high, varying between 96 per cent. at half-load and 98 per cent. at full load. The cost at present-day prices is £2 per kVA for small sizes up to 100 kVA, and down to £1 per kVA for larger sizes.

The Frequency Changer.

A frequency changer is only applied to small sections of the supply and not for linking together large systems having different periodicities. The efficiency varies from 89·5 per cent. at half load to 92·5 per cent. at full load. The power factor can be adjusted to unity, and the cost at present-day prices is £5·16 per kW.

Lighting and Power Applications.

Most thickly populated centres of supply are dealt with by a d.c. three-wire network, divided into reasonably sized sections, each one fed by a distinct sub-station through low tension d.c. feeders. Sub-stations are commonly equipped with rotary converters or La Cour motor converters, drawing their supply from extra high tension polyphase a.c. mains. Recently the mercury arc rectifier has found favour. When the price of this is reduced from its present high level, it should prove a formidable rival to the rotary converter. The advantage of using d.c. in a thickly populated district is largely due to the possibility of installing storage batteries.

The overall efficiency of a rotary converter sub-station equipped with a storage battery, over a period of twelve months, and converting an output of about nine million units, amounts to 87 per cent.

The present-day cost of such a sub-station, including land, buildings, plant, battery and switchgear, amounts to £19·9 per kW for a two storey sub-station and £17·4 per kW for a single storey sub-station.

A limitation to the capacity of the d.c. sub-station is imposed by the loading up of the low tension feeders. A point is reached when it becomes practically impossible, without a very heavy expenditure on additional copper, to maintain the proper pressure in the outlying parts of each district. The best way of handling such a condition is to instal automatic rotary transforming plant or mercury arc rectifiers in the outlying districts, feeding back into the distributing network at times of heavy demand.

Apparatus can be made entirely automatic, or semi-automatic by connecting to the main sub-station through pilot wires.

The present-day cost of such plant installed in single units of 250 kW capacity amounts to :—for the automatic rotary converter equipment, £23·7 per kW, and £17·1 per kW for the mercury arc rectifier.

In a thinly populated residential district the use of d.c. is hardly justified, and low tension a.c. supply has to be adopted.

The comparison of the cost of three schemes for dealing with a suburban area of about 13 sq. miles at present-day prices works out as follows :—

Three automatic mercury arc rectifier sub-stations, each comprising one 230 kW rectifier, one 100 Ah battery for balancing purposes, switchboard and sub-station buildings, with direct current feeder and distributor mains	£65 per kW
Three automatic rotary converter sub-stations, each comprising one 250 kW rotary converter, switchboard, station buildings and direct current feeder and distributor mains	£58·5 per kW
Six static transformer sub-stations, each equipped with one 100 kW transformer, with switchgear, sub-station buildings and alternating current distributing mains	£26 per kW

The efficiency of operation of these three systems of supply, reckoned from the high tension input to the sub-stations to the supply delivered at the consumers' premises, and assuming a load factor of 15 per cent. per annum, works out as follows :—

For the automatic mercury arc rectifier equipment	89 per cent.
For the automatic rotary converter equipment ..	84·5 per cent.
For the static transformer equipment	95 per cent.

Tramway Traction.

For tramway traction purposes rotary converters, synchronous and induction motor generators are chiefly used. In thickly populated districts tramway traction plant can be worked in conjunction with the lighting and power plant, but in country districts such equipment is costly to operate, and automatic rotary converting plant and mercury arc rectifiers will probably be used. Control can be conveniently obtained over great distances from a single centre by means of pilot wires operating relays.

Railway Traction.

Requirements for railway traction are not so well defined in this country as are those of the two preceding sections.

The standard pressure of 1 500 V (d.c.) recommended by the Advisory Committee of the Ministry of Transport is not being accepted without question. Advocates of the Brighton and South Coast Railway System (single phase a.c. at 11 000 V) consider this a cheaper proposition. On the other hand d.c pressures above 1 500 V can be obtained and used with safety.

The mercury arc rectifier can supply d.c. at 3 000 V, or the rotary converter utilised by coupling the d.c. ends in series. In order to utilise 3 000 V train motors would be run two in series with 1 500 V on each.

It is doubtful whether rotary converters will be suitable for these higher d.c. pressures. On a 25 cycle system they are more satisfactory than with 50 cycles.

Sub-stations for railway traction should be automatic in operation, and La Cour converters, induction motor generators and mercury arc rectifiers can be conveniently adapted.

The use of single phase alternating current for ordinary traction purposes requires only static transformers installed at intervals along the line to reduce the pressure from 66 000 or 110 000 V to the line pressure of 11 000 V.

Continental experience indicates that frequencies not exceeding 25 cycles are desirable for single phase operation. Frequencies as low as 16⅔ are generally adopted.

Automatic Operation of Sub-Stations.

Sub-station apparatus should be designed to automatically control the starting and stopping of the plant. For a single unit, feeding into a network control is effected by relays actuated by the pressure of the line supply. For a number of units feeding into a network control would be better determined by the current supplied from the group. It is advisable to allow a time lag of about five minutes before the control actually operates, especially in automatic sub-station plant for traction purposes.

Typical Sub-Station Lay-outs.

The single-storey sub-station is cheaper to build and equip than the two-storey sub-station, but the space occupied by this type is greater, hence in a thickly populated district a two-storey sub-station may be adopted. The battery room is then arranged over the machine room, and this necessitates a stronger and more costly building.

The incoming high tension cables are housed in a trench on one side of the building, the outgoing low tension cables in a trench on the other side. The h.t. switchboard is disposed over the h.t. cable trench ; thence the supply is passed into the transformers, into the rotary converting plant, and to the l.t. switchboard situated over the l.t. cable trench. Space is provided also for feeder boosters and balancers.

The heavier plant should be under an overhead travelling crane to afford facilities for installing and overhauling.

In the one-storey sub-station all apparatus is on one floor, and the battery room is built alongside the station on the l.t. side. In the two-storey sub-station transformers, rotary converting plant and balancers are installed on the ground floor ; h.t. and l.t. switchboards on galleries carried between the overhead crane stanchions and the outer walls. The battery room is overhead. Space must be provided for an attendant's office, with simple cooking facilities, and a heating chamber to maintain a temperature of 55° F. in the winter ; ample ventilation is necessary in summer.

Battery Room Design.

As regards the battery room in the early days trouble was experienced in providing and maintaining an acid-proof floor. Asphalt becomes soft and is not impervious to acid. Ultimately a floor was developed constructed of ½ in. of asphalt laid on the concrete and a 2½-in. hard pressed blue brick tile laid on this, place ¼ in. apart and run in with hot pitch. This is impervious to any acid.

A roof of ordinary steel construction over the batteries is not recommended, as acid spray damages the steel work. A paint of the best red lead and boiled oil put on in five coats and finished in ordinary colour paint lasts as long as any special material, but this is not absolutely impervious. The best construction is to put a flat concrete roof and to case in all the joist work in concrete, so that there is no exposed metal of any kind to be attacked.

Ample ventilation should be provided in the battery room by means of fans. With batteries of 2 000 Ah. capacity and over, it is necessary to provide acid neutralisers, screens of finely perforated lead plates, over which water is allowed to trickle, and through which the air is drawn.

The operating efficiency of a sub-station is about 87 per cent. per annum. The actual working cost at present-day prices for

a sub-station containing 4 000 kW of rotary converting plant with a maximum load of 3 560 kW, and an annual converted output of 9 200 000 units, supplying a l.t. 3-wire power and lighting network and an overhead tramway traction system, is as follows :—

	£	Pence per unit sent out.
Interest at 6 per cent. and Sinking Fund according to the life of the buildings and plant on a capital expenditure of £79 732	8,368	0·218
Rates and taxes	810	0·021
Wages of attendants on shift (eight men)	2,063	0·054
Wages of maintenance men	1,130	0·029
Costs of materials used for repairs and maintenance	380	0·009
Proportionate amount for supervision ..	456	0·0011
Costs of units used on the works reckoned at ¾d. per unit	527	0·014
Total	£13 734	0·356

Static Transformer Sub-Stations, A.C. to A.C.

This is a simple and cheap arrangement, comprising a small building equipped with switches for controlling the incoming and outgoing h.t. cables, a static transformer generally of 50-100 kW capacity, equipped with a h.t. switch, fitted either with automatic overload control or combined with h.t. fuses, and a l.t. switch combined with fuses, for connecting to the l.t. distributing network. The cost of such a sub-station is now about £6 per kW.

With overhead lines transformers are frequently fixed to poles, l.t. connections being made either to overhead lines or underground distributing cables, probably the cheapest form of distribution. In America this method has led to "open air sub-stations." Transformers and switchgear are in weathertight cases, installed in the open, and fed from e.h.t. overhead mains, at pressures of 150 000 V. This may be suitable in the dry American climate, but would not prove to be satisfactory in this country.

Large Consumers' Sub-Stations.

For consumers taking large power supplies of 150 H.P. and upwards, it is usual to provide an e.h.t. supply, which the consumer transforms and distributes in his own premises. The costs of the Supply Department's panels at present-day prices are roughly £148 per cable panel and £173 per consumer's panel. A minimum of three panels is required, but in a large works actually six or nine panels are installed to provide sufficient alternative sources of supply. The maximum capacity of each of the incoming cables is 2 000 kW.

Power Factor.

The power factor can be corrected in sub-stations equipped with rotary converters and other synchronous converting plant, but in the case of long h.t. feeders supplying large consumers it is important to correct at the consumer's premises and to give inducements to consumers to adopt such an arrangement.

A simple apparatus is an ordinary condenser attached to the l.t. side of the transformer. Another device is the Kapp vibrator, which can be attached to individual induction motors and arranged to correct the power factor to unity.

The cost of such apparatus suitable for use on 25 cycle circuits at present prices is as follows :—for condensers £9 9s. per kVA, for vibrators £3 12s. per kVA.

DISCUSSION.

Mr. S. J. WATSON (Bury) said Mr. Chattock dealt with the speed of 500 revs. per min. only, but during the last few years speeds had been pushed higher, and at present 1 000 kW rotaries were being made to run at 1 000 revs. per min., and he believed makers were prepared to go to higher speeds. In consequence the prices were relatively lower, the machine was as good and the efficiency slightly higher. It was reasonable to say one could get a rotary with transformer and switchgear at less than £4 per kW. Those who had purchased self-synchronising rotaries during the last year or two would realise their advantages. They could be run up quickly and put on the bars in less than half a minute in the smaller sizes. The old battle on the use of rotaries or synchronous or asynchronous motor generators had been revived in this paper. Rotaries had been much improved during the last few years, but they still had certain defects. No rotaries would hold in when a bad short on the e.h.t. side set up surges, whereas a synchronous motor-generator was far less sensitive. The author referred to "the relatively less reliable system of low tension a.c. in comparison with d.c." But from the generation right through to the detailed distribution the a.c. system was equal to and in many cases far better than d.c. Almost the sole advantage of d.c. was the possibility of using storage batteries when the loads were small, and it was possible to shut the plant down. But as a system grew and the plant had to be run over 24 hours, a.c., and especially single phase, was simpler and better than d.c. The only other advantage of d.c. was in speed regulation.

Cheap and Abundant Supply Impossible.

Mr. S. E. FEDDEN (Sheffield) thought it would be impossible to give a cheap and abundant supply of electricity on any large scale by using the system the author advocated. To lay minds the complications must appear enormous, and to skilled minds the capital expenditure was enormous. At Sheffield they had been endeavouring to cheapen substations, and had been assisted very much by the ironclad switchgear. In the substation they had evolved the door frames and doors cost £50, at present-day prices, and materials and labour for the concrete erection, £100. The whole station cost £150 exclusive of timber for the concrete sheeting, the cost of which was spread over a number of substations. The door frames were put up and concreted in, and when the floor was down the concrete was built up. The ironclad switchgear was put in through the door on one side and the transformers through the other side. Instead of putting up kiosks the same thing was done on a smaller scale, and 11 000 V could then be handled in any outlying district. Those little concrete buildings only cost £30. The cost of a 2 000 kW substation was : building, £294 ; e.h.t. gear, £600 ; l.t. gear, £75 ; e.h.t. transformers, £1 258, and l.t. transformers, £286. The cost was only £2 or £3 a kW instead of £5 or £6. In the case of mercury arc rectifiers the figure was about £32. We could not sell cheaply on that capital expenditure. Batteries were all right for small country houses, but one could not distribute cheap electricity with an efficiency of 60 per cent., and there was very large capital expenditure. Automatic rotary substations would no doubt be useful for railway and other big work, but the big capital expenditure barred them out for other purposes. Mr. Chattock made a point of the great advantage of keeping up the power factor by having all these rotary substations, but it was a most expensive way of doing it. Low power factor was a bogey on most distribution systems.

Colonial Experiences.

Mr. W. H. ALABASTER (Melbourne) said he had recently had to go into the design of rotary substations and numerous static substations. He agreed as to the desirability of limiting as far as possible the area to be supplied by d.c. He had recently put forward a proposal to cut off an outlying district which was poorly developed, and arranged for it to be transferred to the a.c. system. Half the d.c. area was run without a battery with satisfactory results. In the most important area, however, there was a 4 000 Ah battery. He was rather appalled by the author's figure of 0·36d. per unit being added to the working cost by a fairly large substation. He thought that was due to the inclusion of a battery and to the fact that Mr. Chattock was providing for smaller substations than the one to which he had referred. For the last few months he had been running a 5 000 kW frequency changer for connecting a 50-cycle power house with a 25-cycle railway power house, and the result had been so good that he did not see why they should not be satisfactory elsewhere.

Batteries not Justified.

Mr. R. B. MITCHELL (Glasgow) agreed with the first two speakers with regard to system of supply. He did not think batteries in substations were justified, on account of the cost. In Glasgow there was one substation of 6 000 kW capacity, and there was room for another 3 000 kW. If he put in a battery of 6 000 kW, according to Mr. Chattock's figures the cost would be £210 000. In Glasgow they had also installed a rectifier, but their experience had not been so fortunate as Mr. Chattock's. It was of 1 500 kW capacity in three cylinders. That introduced complications. One of the cylinders gave trouble, apart from the relationship of one cylinder to another, and the coils and switchgear caused complications. At the same time he felt sure the makers would get over the difficulties and would be able to run three cylinders in parallel in one substation with success. At Glasgow they had decided to risk 25 cycle supply to outlying areas.

Witton Works Revisited.

At the conclusion of the meeting the party were taken round the various departments of the Witton works, special attention being given to the electric kitchens in the Club premises and to the exhibition of domestic and other electrical labour-saving appliances. A short description of the former will be found elsewhere. As for the latter it enabled visitors to see in peptonised form the activities of the firm on the less impressive, if ultimately more useful side, of electrical engineering. It is hardly necessary here to dilate on the details of "Magnet" domestic equipment, but the display should have had the effect of hastening the conversion of those who believe that the perfect, or even the fairly perfect, apparatus is still to seek. In other fields we noticed the Haydn Harrison lantern and a warning apparatus for platelayers which makes use of a sensitive relay and bell operated by the vibration of an approaching train.

At the conclusion of the works inspection the company were entertained to luncheon in the Magnet Club by the General Electric Co.

Mr. Hirst on Cheap Electricity.

In reply to the toast of "The General Electric Company," proposed by Mr. S. T. Allen, Mr. Hugo Hirst, who presided, recalled the days of 1914, the last time that the I.M.E.A. visited Witton, when the whole world was suffering from a sickness from which it had not yet recovered. It would only recover when Britain recovered and it was therefore our duty for the sake of universal good to concentrate on our own recovery. In his opinion the only way in which we could recover was by the increasing employment of electricity. To that extent the aims of the Association and the G.E.C. were identical. To produce cheap electricity wherewith to inoculate England would strengthen the electrical industry and every other industry that depended on cheap power, so giving employment and increase of strength. It must be realised that there could be no more living for ourselves. It was the aim of the G.E.C. to build up a concern as large as any and the I.M.E.A. could help them by placing at their disposal the cheap unit which was the most essential raw material for fighting the competition from abroad.

Annual Dinner.

In the evening the annual dinner of the Association was held at the Royal Field Artillery Headquarters, Mr. S. T. Allen being in the chair. A large number of members and guests were present, including Mr. J. S. Highfield, the Mayor of Wolverhampton and Dr. S. Z. de Ferranti.

Replying to the toast of "Our Guests" proposed by Mr. R. A. Chattock, Dr. Ferranti said the convention gave an excellent opportunity for renewing old friendships and making new ones. He referred to a visit he had paid forty-one years ago to Wolverhampton in connection with the lighting of the Ironmasters Exchange The effort of keeping the lights going on that occasion had been so worrying that he had decided he must give up electrical engineering if he could not worry less, and in any event he had had no opportunity of seeing the beauties of the town. He was only too pleased to endorse the remark that Mr. Hirst had made that afternoon that we required far more electricity. The country was in a difficult position and there was no surer way to success than by increasing the use of electricity for every possible purpose. The I.M.E.A. had the great responsibility of being the trustees for electricity users and that great responsibility could only be met by endeavouring greatly to increase the use of electricity. It was true there were difficulties in the way but there must be no waiting for perfection. Electricity could, and should, be used for every purpose for which combustible was now employed, for in every case electricity did the work much better than anything else. It was really a question of salesmanship for there could be no better thing to sell than electricity and we must therefore increase its sales by pushing it for all it was worth and by getting together and devising means for bringing about this result.

In proposing the toast of the "Incorporated Municipal Electrical Association," Mr. J. S. Highfield said that municipalities were at present engaged in a great electrical work. Such stations as Nechells, Dalmarnock and Barton made it certain that municipal electricity supply was going to endure. On the Tyneside they could see the work of private enterprise and that was also going to endure. To bring about the position that Dr. Ferranti had outlined the first matter of importance was to realise that companies and municipalities must assist each other, and if they would only work together Dr. Ferranti's dreams might well have a chance of coming true.

The toast was responded to by Mr. S. T. Allen who said he would like to reply to the complimentary things that had been said about the municipalities by referring to the position of the Institution of Electrical Engineers which was known and respected throughout the world. As he had already pointed out, the I.M.E.A. was the oldest municipal association, and it was therefore a pleasure to have with them to-night representatives of similar associations in Australia and South Africa.

Friday, June 23.

This morning the annual general meeting was held in the Grand Theatre, Wolverhampton. The proceedings opened by the President reading a telegram from the Prince of Wales, expressing his thanks for the Association's message of congratulation upon his return from the East.

The New President.

The President next announced that there was only one nomination for the office of President, and he therefore declared Lieut.-Col. W. A. Vignoles (of Grimsby) duly elected.

Lieut.-Col. W. A. Vignoles, in thanking the members for his election, asked them to support him by reading the monthly report that was sent to them and answering the conundrums which appeared therein.

The President said there was also a single nomination for the Vice-Presidency, and he declared Mr. S. E. Britton, of Chester, duly elected.

The Hon. Solicitor (Mr. P. M. Heath), the Hon. Treasurer (Mr. H. Faraday Proctor), and the Hon. Secretary (Mr. A. C. Cramb) were re-elected unopposed.

The President read a resolution electing Mr. F. Ayton, Past President, an Honorary Member.

The Expenses Problem.

Mr. Faraday Proctor, at the request of the President, dealt with the question of the payment of the expenses of members attending Council meetings. The expenses of the Association were at present about £1 500 per annum, and the expenses of individual members of the Council in travelling to London and the provinces were another £1 500, so that if the Association were to pay the whole of those expenses, the total would be about £3 000, but if it paid the travelling expenses only, the amount required would be £550 less. The Council put forward a scale for drawing from the individual undertakings 1d. for every £20 of gross revenue, which would bring in £3,000 per annum. An alternative was to obtain income by the same means, with a maximum of £30 instead of £50. That would mean that about 16 of the largest undertakings would pay £30, whereas under the first alternative they would pay £50. The contribution of the other undertakings would be 1d. per £20 of revenue, subject to a minimum of £5. The balance of the letters received by the Secretary expressed disapproval of any alteration.

Mr. A. C. Cramb said the Municipal Tramways Association considered this question last year and turned it down. Their subscriptions, however, were two to three times those paid by members of the I.M.E.A.

Mr. S. J. Watson (Bury) said the expenses of the Council of the Borough Treasurers' Association were met out of the borough funds.

Coun. V. Blessley (Hampstead) agreed that the expenses of the Council should be borne by the authorities generally, but it seemed an unfair way to meet the expenses by charging so much on every £20 of gross revenue. He proposed that the contributions paid by local councils should be increased by 100 per cent. with a limit of £50.

Ald. A. Senington (Bristol) seconded Mr. Blessley's amendment.

Coun. E. H. King (Islington) moved that the question be deferred until next year. Some Councils would leave the Association if the matter were pushed now.

Ald. R. Dalton (Carlisle) said he seconded this amendment. To put a limit of £50 on the large undertaking was not fair to places like Carlisle.

Mr. W. C. P. Tapper (Stepney) said the figures put forward by the Council would not involve a very large increase for a small undertaking, but the proposal of Mr. Blessley would have that effect.

Mr. Hinnell (Willesden) thought the Association should fall into line with other associations that paid the expenses of their executives. The Council should divide into three or four panels, each panel meeting for three or four months of the year, and that the whole Council should only meet about once a quarter. A committee of two or three always did better work than one of 20 or 30. His proposal would cut the expenses by about 40 per cent.

After further discussion, the amendment (that nothing be done for 12 months) was carried.

The Annual Report.

Mr. A. S. Blackman (Sunderland) moved the adoption of the Council's report and the accounts, of which we give an abstract below:

The Council, in submitting their 27th annual report, state that the work of the Association has progressed satisfactorily during the last twelve months, and that the results attained show that it is being relied upon more and more to look after the interests of municipal electricity supply authorities in many directions.

Membership.

The total number of municipal electricity supply undertakings belonging to the Association is now 206, representing a population of 19 665 270. This represents 81 per cent.

of all the undertakings eligible. Of the 47 municipal authorities which have not yet joined the Association, 43 are in the provinces, and represent a total population of only 788 746. Four London municipalities are not yet members, but the difficulty which precluded them from belonging in the past has now been removed under Section 30 of the Electricity (Supply) Act, 1919. The Council would be glad if members would use any influence they may have with the undertakings referred to above in order that this small minority may be induced to join the I.M.E.A., and thus pay their share, in the form of the annual subscription, towards the expenses which are incurred for the benefit of all municipalities.

During the year applications for membership were received and accepted from Long Eaton, Stafford, Cheadle and Gatley, Swinton and Pendlebury and Cambuslang, and the Council have extended to them a very hearty welcome. It is to be regretted that Great Yarmouth and Morley have resigned membership.

Under the Articles of Association the Bootle Corporation is no longer eligible for membership owing to its electricity undertaking having been transferred to Liverpool Corporation.

Committee Work.

A section of the report amounting to three-fifths of the whole is devoted to drawing attention in great detail to the nature and number of the various Committees upon which members of the I.M.E.A. have been actively engaged during the past year. These include the five standing Committees of the Association, and special Committees on agreements, and with the B.E.A.M.A., the E.L.M.A. and the E.C.A. The Association is also represented by one or more members on the B.E.D.A., the various Sub-Committees of the British Engineering Standards Association, the Electric Vehicle Committee, the Revising Committee of the I.E.E. Model General Conditions of Contract, the I.E.E. Committee on Overhead and Underground Conductors, the I.E.E. Wiring Rules Committee, the National Proving House Committee and the Railway Rates Joint Conference.

Charges for Tramway Supply.

The Council were asked to investigate the charges for tramway supply laid down in the I.M.E.A.-M.T.A. Joint Report of 1911, but after a *questionnaire* had been circulated, it was decided to take no further action for the present.

The Subscription Question.

At the last Annual General Meeting, the Council were requested to make arrangements for the expenses of members of the executive attending meetings to be borne by the whole of the undertakings who benefitted from the work of the Council. An investigation of the matter shows, however, that this would cost £1 500 per annum, if all expenses were covered, and that it would not be possible to do this without increasing the subscription, a policy which is not wise at the present time. The matter was discussed at the Annual General Meeting as reported above.

Marking Underground Cables.

The difference of opinion between the Association and the G.P.O. on the question of marking underground cables is mentioned as are also the important provisions contained in the Grimsby Corporation (Omnibus Act), 1921.

As regards the maximum repayment periods at present allowed for apparatus to be let on hire, the Electricity Commissioners were informed that as much apparatus now on the market was not standardised, the Association did not press at the moment for any extension of the seven years period.

The Minimum Charges Clause.

In connection with the interpretation of the wording of the Minimum Charges Clause in Provisional Orders, the Commissioners stated that they would recommend the Minister of Transport to circulate an explanatory memorandum pointing out that the clause was intended to cover any case where no units were registered on the consumer's meter. The Honorary Solicitor also recommends that it would be advisable to regard 92 days as being the shortest period for which a minimum charge could be made. Manufacturers are going into the matter with a view to meeting the demand for a meter that will read below 2·5 A.

Stand-by Supplies of Electricity.

Members have frequently drawn attention to the unfairness of Section 15 of the 1909 Electric Supply Act, which, from the legal aspect, does not cover those premises which have a private or independent source of electric supply, and require a stand-by supply of electricity from the public mains. In many areas the difficulty has been overcome by the insertion of a clause in a private Act to cover all cases of stand-by supplies. The Council took up the matter with the Electricity Commissioners in January last, and obtained a promise that steps would be taken to insert a clause in the Electricity (Supply) Bill, 1922, so as to make it perfectly clear that a sufficient income should be obtainable to cover capital charges, etc. This point is dealt with in the Electricity (Supply) Bill, 1922, now under consideration by Parliament.

Financial Position.

The annual accounts show that the Association is financially in a satisfactory position. The total receipts for the year were £2 090, and the total amount expended £1 808.

In a discussion on the report, Mr. F. W. PURSE (West Ham) said he was a whole-hearted supporter of compulsory wiring regulations. The power companies as a rule were opposed to compulsory rules, and quite a number of municipal authorities were equally opposed.

The Monthly Report.

Referring to the monthly reports, which were sent out to members, Mr. S. J. WATSON said he commended their usefulness. He appealed to engineers and chairmen to obtain the necessary quantities of these reports and circulate it at least among the members and the Committee. It would be of assistance in enabling them to understand and appreciate many of the difficulties they were up against.

Mr. A. C. CRAMB, as responsible editor of the monthly reports, invited chairmen and engineers to criticise them, adversely or otherwise, and let him have any information of interest to other readers.

The New Council.

The PRESIDENT then announced the result of the ballot for the election of new members of Council. The members elected were: *Committee Representatives*—Ald. A. Wilkinson (Luton) and Ald. H. Leese (Stoke-on-Trent). *Engineers (Large Towns)*—Mr. R. B. Mitchell (Glasgow), Mr. W. H. J. Wood (Bolton), and Mr. H. R. Burnett (Barrow-in-Furness). *Engineers (Small Towns)*—Mr. T. Hall (Burton-on-Trent).

Mr. N. STANILAND proposed that the Electricity Commissioners be informed that the Association is desirous that the Institution Rules, when adopted by any supply authority, should be enforceable on contractors.

Mr. A. DE RENZI (Newcastle-under-Lyme) seconded the motion, and it was carried.

Mr. L. L. ROBINSON suggested that the Council should arrange in the autumn of this year an excursion to the capital station at Gennevilliers, which was to supply Paris.

The PRESIDENT said the matter would be considered by the Council.

The Commissioners' Expenses.

Mr. F. NEWINGTON (Edinburgh) moved a resolution that "in the opinion of this Association the expenses of administration of the Electricity Commissioners should be a national charge."

Mr. F. L. R. STEWART (Rawtenstall) seconded the motion, and said there were amendments down in the House of Commons for modifying the 1919 Act by making the Electricity Commissioners' expenses a national charge. A resolution by that Association supporting such amendments would help a great deal.

Mr. F. W. PURSE said that Treasury control would mean more red tape than ever.

It was ultimately agreed to refer the matter to the Council for consideration and report.

Votes of Thanks.

Votes of thanks were accorded the President and Council, and to the Lord Mayor and Corporation of Birmingham and the Mayors and Corporations of Wolverhampton and Stoke-on-Trent for the assistance they had given in making the Convention a success, and the Mayoress of Wolverhampton received a special tribute for her assistance.

On the motion of Coun. THICKETT (Gt.-Grimsby) the members passed a vote of sympathy with Lady Wilson in her bereavement by the murder of her husband, Field Marshal Sir Henry Wilson.

This concluded the business in the Convention. In the afternoon parties visited the Wolverhampton Corporation Generating Station, and thus brought to an end a successful, if somewhat tiring, meeting.

Correspondence.

THE INTERNATIONAL RAILWAY CONGRESS.

To the Editor of THE ELECTRICIAN.

SIR,—In his article in your issue of June 2, 1922, Mr Roger Smith seems to indicate that the choice of system for railway electrification depends appreciably on the mode of generation, and instances hydro-electric stations as being suitable for supplying low-frequency, single-phase current, whereas steam turbine, 50 cycle stations would lead to the adoption of the direct current system. The suggestion is interesting, but does a broad view of the situation really support the contention? Thus the $16\frac{2}{3}$ cycle railways in Germany, namely the Dessau-Bitterfeld and the Silesian lines, are supplied from steam stations; likewise the 25 cycle, Hamburg-Altona line. In U.S.A., the Norfolk and Western, the New York, New Haven and Hartford, and the Pennsylvania Railroads are worked with single-phase current at 25 cycles supplied from steam stations. Similarly the Brighton line in Great Britain.

In another place, we read: "Those countries like Belgium, Holland and Great Britain . . . have adopted 1 500 V direct current"; but later, "The Advisory Committee to the Ministry of Transport very properly left an open door in the matter of choice of system"—let us hope the latter is the correct statement.

I can agree with Mr. Roger Smith, however, when he says: "People have talked system so long that they have forgotten that the differences in the cost of working one system, as compared with any other system at present in use, do not exceed one or two per cent. on the total cost of running the railway." In this country the coal pits will probably have to be much deeper before main-line electrification becomes a domestic problem. Instead of worrying so much about "system" therefore, it would be better to encourage our manufacturers to lay themselves out to get whatever work there is to be had. In this respect it seems to me that the policy of the Swiss electrical firms who supply any type of equipment is a much better example to follow than that of the American General Electric Co., which advocates so persistently the direct current system. Ought we not to encourage the North-Eastern Railway to proceed with their direct current project and the Brighton Railway with their single-phase project in order to try out things for ourselves and to give our manufacturers the necessary experience?

STANLEY PARKER SMITH.

City and Guilds (Engineering) College,
Exhibition Road, S.W.7,
June 27, 1922.

Electricity Supply in Victoria.

The Electricity Commission of the State of VICTORIA is developing its policy in a systematic way, and a survey of all fuel resources is to be made, though for the moment attention is being concentrated on the Morwell brown coal scheme. In a recent lecture, the chairman of the Commission (Sir John Monash) pointed out that there was no effort in which co-operation was so beneficial as in the generation and distribution of electricity, because the needs of the community were always less than the sum of the needs of the individual consumer. That was why the generation and distribution of electricity had been declared a public utility in Victoria. When the Commission was first appointed its first duty was to survey the electrical resources of the State. The sources of generation were threefold, namely, black coal, brown coal and water power. Victoria's black coal resources were at present very meagre, so the choice lay between brown coal and water power. There was no doubt that the state was very rich in water power resources, but the territory was almost inaccessible, and little was known of the behaviour of its streams throughout the year. Before electrical schemes could be carried out, accurate information would have to be obtained. Want of knowledge, coupled with the possession of rich brown coal deposits, made them decide upon a scheme for using brown coal. Deposits of the latter pervaded practically the whole of Gippsland. There were three open-cut areas (at Morwell, Traralgon and Welshpool), about 30 square miles in area in each. The coal was from 160 to 600 ft. thick. In one corner of the Morwell area, where minute exploration had been made, one square mile contained more coal than Victoria could use in 150 years.

He did not altogether exclude black coal from the power schemes of the future, because there were no doubt fields to be discovered, and water power would take its place in the scheme in the not distant future; but whatever happened there would only be one State electricity scheme. He condemned the suggestion put forward for a flat rate to be charged for all power sold by the State electricity scheme. The cost of electricity was governed by the length of transmission.

N.A.S.E. Smoking Concert.

There was a large gathering of members of the NATIONAL ASSOCIATION OF SUPERVISING ENGINEERS at the smoking concert held on June 15 at the St. Bride's Institute, London, on which occasion the President, Major T. Vincent Smith, who has been obliged to resign on account of ill health, formally introduced the new President, Mr. W. E. Highfield.

Major Smith accompanied several members in their songs, and the rest of the entertainment was provided by Mr. Alfred Stone's Concert Party. Just before the interval the President addressed the gathering.

He had just completed his year of office as President, and during that time had enjoyed the most loyal co-operation of the members in carrying out the necessary work connected with the position. Unfortunately, he found he was unable to devote the time and energy necessary to maintain the duties of an active President, and as he did not want to be a sleeping partner, he was reluctantly obliged to resign from the position. However, his retirement enabled him to introduce the President-elect, Mr. W. E. Highfield, who was the most suitable man the Association could possibly have found. In conclusion he wished the Association every prosperity in the future, and if there was any way in which he could further help them, he would be only too pleased to do so. Mr. Highfield was then welcomed as the new President of the Association and took the chair.

In his opening speech the incoming President said he highly appreciated the privilege of becoming the President of such an Institution and would do his very best to help to justify their choice. The Association was really one of the most important in the country, as it represented the best brains and work of an industry that it was now impossible to do without. He only hoped his own experiences would be of some use.

Australian Wireless Services.

The shareholders of the AMALGAMATED WIRELESS (AUSTRALASIA), LTD., have sanctioned an amendment of the company's articles of association in order to comply with the terms of the agreement entered into with the Commonwealth Government. The chairman (Sir Thomas Hughes) explained that the agreement with the Commonwealth was the outcome of at least three years' effort on the part of the Government and the company to establish an effective commercial wireless service between Australia and Great Britain. An exhaustive series of experiments had been carried out by the company in Australia, and they had an experimental station able to receive messages direct from Europe and the Atlantic Coast of America at all hours of the day at speeds up to 30 words a minute. The Commonwealth Government had operated a number of short-range stations for communication with merchant ships round the coast of Australia, but the service had involved the Commonwealth in a heavy annual loss, because in its present condition it could not possibly become profitable. It was possible to eliminate the loss by installing more modern apparatus and merging that service with a properly organised commercial service for communication with countries overseas. The co-operation of the Government and the company was therefore necessary. The company's capital would be increased to one million pounds, and the Commonwealth would subscribe for 500,001 shares. The Commonwealth would appoint three directors and the private shareholders would also have the right to elect three directors. The six directors would mutually select a seventh.

The company will proceed at once with a comprehensive plan of development, including a direct commercial service between Australia and England; direct commercial service between Australia and North America; and feeder stations in each capital city. The existing coastal service of the Commonwealth will be taken over by the company. During the period of reconstruction the company is guaranteed against any loss on conducting existing services, but when the new stations are ready the combined services will be carried on as one undertaking and the revenue from the coastal service will be a valuable contribution to the total revenue.

The chairman stated that when their first programme was completed they would have one of the most efficient high-power wireless stations in the world, capable of sending and receiving messages simultaneously between Australia and England at high speed. The main trunk station would be situated near Sydney or Melbourne, but the operating staff would be in the city. The capitals of all the States will be able to send and receive their messages by wireless direct to and from the main operating centre. A rapid press service will also be organised. The company will carry all classes of Anglo-Australian messages at $33\frac{1}{3}$ per cent. reduction on existing charges, so that full-rate and code messages will be 2s. per word, deferred messages 1s., and week-end messages 6d. per word.

The United Fruit Co., of Boston, have placed an order with CAMMELL, LAIRD AND CO. for three insulated motor ships. The vessels are to be of about 4 000 tons gross, and will be propelled by electric motors, the current being generated by Camellaird-Fullagar Diesel engines. It is claimed that by the adoption of this combination of machinery there is an enormous reduction in fuel consumption, and greatly increased cubic space and dead-weight capacity, while the machinery lends itself to the greatest flexibility of control.

The "Magnet" Club and Electric Cooking.

The Witton factory of the General Electric Co. is distinguished not only for its engineering productions, but for the social work which is undertaken for the good of those there in employment. A standing monument to the interest which the firm take in their employees' welfare is the magnificent club house which was erected by the company in memory of many who went from Witton to the front and did not return. Some details of these premises have already been given in

FIG. 1.—GENERAL VIEW OF KITCHEN.

THE ELECTRICIAN, and those attending the I.M.E.A. Convention last week were given an opportunity of inspecting them for themselves.

A Satisfactory Answer.

The first question that we hope most readers of THE ELECTRICIAN ask when they are shown a kitchen in an electrical factory is: "Is electric cooking used?" We are glad therefore to record that the Magnet Club possesses an up-to-date electric kitchen, the whole of the equipment for which was manufactured at the company's Heating and Cooking Works, at Birmingham. The kitchen was planned for the supply of meals to a staff and employees approximating 2 000, and has now been in operation for over eighteen months with complete success. The main equipment comprises four ranges, each fitted with three ovens, grillers, steaming ovens, vegetable boilers, fish fryers, stock-pots, hot cupboards, saucepans and boilers, together with the necessary control gear.

In considering the planning of the kitchen, it had to be borne in mind that whilst large numbers had to be catered for, there was no need to make provision for great variety in the type of meal. Any portion of the plant for cooking in any particular way had to be capable of providing for the full number of diners at any one time. In the design of the whole of the appliances, the guiding principle adopted was simplicity of construction, so that access could be easily obtained to any particular part. In the ovens the whole of the electrical portion can be readily removed, leaving an entirely free space for cleaning. There are no crevices for fat or dirt to accumulate, and all seams are welded.

With the exception of the stock pots, all appliances have self-contained elements, the problem of vegetable boiling has been successfully solved by providing such loading that an ample reserve of heat is available to raise the temperature quickly to the boiling point.

The following details of the equipment are of interest:—

Ovens. Four ranges are provided, each fitted with three ovens of 2 cub. ft. capacity, wired for 5 kW maximum consumption, with low heats of 2⅜ kW and 1¼ kW. They are operated by series parallel switches, the elements being of the Firenza type. On two of the ranges plug receptacles are provided for separately heated utensils.

The grillers are arranged with hot-cupboards above and below, the upper ones receiving the heat from the actual grilling elements. Each half of the griller is wired to consume 8 kW, and is sub-divided again so that only a quarter of the total grilling area need be in use if so desired.

The steaming ovens are double cased and lagged, and the doors are arranged with steam-tight joints. Constant water level attachment is fitted, to avoid the possibility of boiling dry. The current consumption 5 kW maximum, with low heats of 2½ and 1¼ kW.

The vegetable boilers are each of 30 gallons capacity, and are made in heavy copper, double cased. The loads are 6 kW, 3 kW,

FIG. 2.—ANOTHER VIEW IN THE KITCHEN.

and 1½ kW, and they are fitted internally with the usual wire baskets and strainers, etc.

The fish-fryers are made with welded steel pans 36 in. by 18 in. by 8 in., the current consumption to each section 6 kW, with low heats of 3 kW and 1½ kW.

The stock-pots are made of heavy copper, and the heating elements are not self-contained, but the stand is provided with hot-plate 20 in. square loaded to 5 kW maximum, with low heats of 2½ kW and 1¼ kW.

The hot-cupboards and carving tables are each provided with three carving wells, heated separately, the consumption for each being 500 W. The hot-cupboards have a maximum consumption of 3 kW.

The saucepans and boilers are all fitted with self-contained heating elements, with series parallel control. Pilot lamps are fitted near the plug receptacles to which they are connected.

The series parallel principle of control has been adopted throughout the whole of the cooking apparatus in the canteen, and pilot lamps fitted to every circuit. The internal connections in the apparatus are almost entirely of stiff strip metal, and the use of beads is almost eliminated. Mica insulation is adopted throughout, except where red-hot coils are used.

FIG. 3.—VIEW OF THE OVENS IN THE "MAGNET" CLUB KITCHEN.

Usco Ash Conveyor at Wolverhampton.

One of the more important economic and engineering problems connected with modern central stations is that of ash disposal. There are those who would take the heroic course in this matter by using oil and doing away with coal altogether but for many reasons the system employed at the Wolverhampton Corporation Electricity Works has more to recommend it.

THE "USCO" ASH COFVEYOR.

The ash conveyor here installed is of the continuous action water-trough type, supplied by the UNDERFEED STOKER CO., and in principle consists, as shown in the illustration, of a horizontal water-filled trough containing a conveyor chain of special construction. The trough is situated below the boiler furnaces and receives the ash direct from the grates through chutes terminating below the water level in the trough. The cool damp ash is removed from the trough by the conveyor to any desired point. It should be pointed out that the action of the conveyor being continuous the load is handled in most economical manner, while other features of this system are its automatic action and the way in which it eliminates manual labour. The power absorbed in running the conveyor is said to be extremely small, while a perfect air seal preventing the admission of air to the combustion chambers is maintained. There is an absence of dust, heat and fumes in the ash tunnel and the storage of hot ashes in hoppers under boilers is avoided.

These Usco conveyors may be installed in any arrangement of boiler house whether with or without basement and are in fact now installed and in continuous use working under a wide range of conditions.

At Wolverhampton the conveyor is set in a basement under a line of six boilers. The trough is built in concrete with cast iron bottom plates and the chain returns inside the trough, the ash dropping through it on to the operative portion of the chain. The continuation of the trough is formed by an elevator inclined at 35 deg. to the horizontal, up which the chain carries the ashes and delivers them into a 50-ton capacity concrete storage hopper from which carts are loaded. The overall length of the conveyor is 225 ft., the trough being 153 ft. long. The conveyor is driven by an electric motor through worm and spur reduction gear and final chain drive. The power absorbed being approximately 2½ H.P. The load handled is about 4 tons of ash per hour.

A Safeguarding of Industries Order.

The draft of the new Order under the SAFEGUARDING OF INDUSTRIES ACT schedules a number of articles on which a duty of 33⅓ per cent. is payable on importation if manufactured in Germany. The articles include illuminating glassware for use with artificial light, not including electric incandescent lamp bulbs, miners' lamp glasses, or oil lamp chimneys.

The list does not, however, include any article of glassware (whether domestic or illuminating) which is only pressed, or any article composed of fused silica, vitreosil, or similar material.

The Order will remain in force until August 19, 1924.

Confirmation of Electricity Schemes.

The Ministry of Transport has made Provisional Rules relating to the procedure in connection with the confirmation of Orders approving schemes of electricity supply under sec. 7 of the Electricity (Supply) Act of 1919.

Under the rules, before the Minister of Transport confirms an Order he will publish, in such a manner as he may think best adapted for informing persons affected, notice of the proposal to confirm the Order, and of the place where copies of the Order may be obtained.

Any person desirous of objecting to the confirmation of an Order must do so by a memorial, addressed to the Minister of Transport, written on one side only of foolscap paper.

Any memorial objecting to the confirmation of an Order must be sent by registered post, addressed to The Secretary, Ministry of Transport, and posted not later than the date mentioned in the notice and a copy of the memorial must be sent in like manner to The Secretary, Electricity Commissioners, Gwydyr House, Whitehall, London, S.W.1.

Every such memorial must be sealed or signed by the person objecting or by some responsible and duly authorised person on his behalf, and must state:—(*a*) The Order or portions of Order objected to, (*b*) the specific grounds of objection, and (*c*) the omissions additions, or modifications asked for.

Not less than 10 clear days' previous notice in writing, addressed to the persons objecting to the confirmation of the Order or their Agents, and to any other persons (or their Agents) whom the Minister of Transport considers to be affected, will be given of the time and place of any inquiry which the Minister of Transport may direct to be held.

The costs of any such inquiry shall, unless otherwise directed by the Minister of Transport, be paid by the parties appearing at the inquiry, or by such of them and in such proportions, at such time and in such manner as the person holding the inquiry may direct.

L.C.C. Tramway Accounts.

The total receipts of the LONDON COUNTY COUNCIL TRAMWAYS DEPARTMENT for the year ended March were £5 160 320, compared with £4 904 427 in 1920-21, and the working expenses were £4 386 891, against £4 623 654, leaving a surplus of £773 429 (against £280 773), or £570 581, after charging proportion of renewals (£202 848).

These figures include revenue from and cost of operating the Leyton Tramways from July 1, 1921, and the amount payable to Leyton Council is £3 599, after deducting income tax, thus reducing the surplus to £566 982. After deducting interest (£293 964), redemption of debt (£353 636), income tax, &c., there is a deficit of £88,757. In the past year the cost of track renewals has been charged equally to capital and maintenance account, but it is anticipated that in the current year the tramways revenue will be sufficient to defray the whole cost of all renewals. The total gross debt was £15 616 069, but £6 713 048 has been paid off, leaving £8 772 227 as the outstanding debt.

A Mercury Turbo-Generator Plant.

The HARTFORD (CONN.) Electric Light Co. has ordered a COMMERCIAL MERCURY BOILER AND TURBINE PLANT for its Dutch Point generating station. The unit, which will be of 2 000 kVA capacity, is claimed to be the first of its kind in the world. Fuel oil will be used, and it is expected to cut down the fuel consumption for the generation of current by 50 per cent. The *Electrical World* states that it is intended to instal a mercury turbo-generator on the top of an oil-fired mercury boiler containing a charge of about 30 000 lb. of mercury. The turbine will be operated by the mercury vapour at rather low pressure, and the exhaust from the mercury turbine generates steam in a modified water tube boiler.

I.E.E. War Memorial.

On Wednesday the memorial, erected in the entrance hall of the Institution of Electrical Engineers' building, to the memory of the members of the Institution who fell in the Great War, was unveiled by Air Chief Marshal Sir H. M. Trenchard, Bart., K.C.B., D.S.O., and dedicated by the Right Rev. Bishop Ryle, K.C.V.O., D.D., Dean of Westminster. The choristers of H.M. Chapel Royal, Savoy, under the direction of Dr. Bromley Derry, and a section of the band of the Royal Engineers, Chatham, attended, and led the singing of "Oh, God, our help in Ages Past" and the National Anthem.

A fuller report of the ceremony will appear in our next issue.

The hand of the assassin has been busy during the last week. Great Britain loses, through the dastardly act of two wretched miscreants, a distinguished soldier and statesman in FIELD-MARSHAL SIR HENRY WILSON; while Germany is deprived by a somewhat similar crime of DR. WALTER RATHENAU, an able engineer and industrial magnate as well as a statesman of some standing and character. As our readers know, Dr. Rathenau was chairman and head of the well-known Allgemeine Elecktricitäts Gesellschaft, of Berlin. In the past we have sometimes criticised the policy of the company, but we regret it has lost its guiding hand, especially under such tragic circumstances.

Parliamentary Intelligence.

S.E. and C.R. Electrification.

Mr. HANNON asked the Chancellor of the Exchequer (House of Commons, June 20) whether the Trade Facilities Committee had undertaken to guarantee capital expenditure and interest of six and a half millions by the South Eastern Railway Company, such expenditure including an amount of about one and a half millions for the erection of a power station for the sole use of the South Eastern Railway Company; and, seeing that such outlay upon a power station by the South Eastern Railway Company would defeat the objects of the Electricity Supply Act, 1919, and of the Electricity Supply Bill now before the House, that the South Eastern Railway Company had undertaken to keep the capital cost of its power station apart from other capital expenditure under its scheme, and also keep separate accounts of costs of generation, so that the travelling public might not suffer from undue capital expenditure and abnormally high costs of generation, and that in the public interest one superstation, as contemplated in the 1919 Act, would more adequately meet the transport and power and lighting needs of the areas affected, whether he would inquire further into this matter?

Sir J. BAIRD, in reply, said: The Treasury have expressed their willingness on the recommendation of the Advisory Committee under the Trade Facilities Act, to guarantee the principal and interest of a loan of £6 500 000 to be raised for the purpose of electrifying the suburban service of the South Eastern and Chatham Railway Company, and for the erection of a power station. As regards the erection of the power station, the recommendation of the Advisory Committee has been given subject to the approval of the Electricity Commissioners, who are holding an inquiry into the applications which have been made by the South Eastern and Chatham Railway Company and other parties for permission to erect a station in the area concerned.

Mr. WISE asked the Chancellor of the Exchequer what is the security the Government would hold against the advance to the South Eastern Railway Company under the Trade Facilities Act?

Sir J. BAIRD: The hon. Member is under a misapprehension. No advances are made by H.M. Government under the Trade Facilities Act which is limited to guarantees of loans raised by the parties concerned. The South Eastern and Chatham Company have undertaken to make annual payments sufficient to cover the service of the guaranteed loan.

Electricity Commission.

Sir JAMES REMNANT asked the Parliamentary Secretary to the Ministry of Transport (House of Commons, June 26) whether, under the Electricity (Supply) Act, 1919, the salaries of the Electricity Commissioners, their staff, office, and other expenses, had to be paid by the authorised undertakers supplying electricity throughout the country; what these salaries and expenses for the year 1921 amounted to; and whether he was aware that a compulsory levy was now being made on the undertakers to recover them?

Mr. NEAL: The answers to the first and third parts of the question are in the affirmative. The net cost of the Electricity Commissioners in the financial year 1921-22 is, approximately, £40,000.

Sir J. REMNANT: Is the hon gentleman aware that since the introduction of this Bill something like £250,000 has been spent by the Electricity Commissioners, which is charged to the authorised electricity authorities throughout the country; and, if that is so, how can he expect, with these expenses being piled on them, that they can reduce the price of electricity?

Mr. NEAL: I cannot accept those figures.

Sir J. REMNANT: They are absolutely correct.

In reply to a further question by Sir J. REMNANT, Mr. NEAL said he understood that the Electricity Commissioners had no information as to the cost incurred by the authorised undertakers supplying electricity in the proposed London and Home Counties Electricity District of the public inquiry held in June and July last. As the result of the inquiry the Commissioners issued in December last a statement of their decision, which was circulated to all interested parties, and were now engaged upon the preparation of a draft special Order.

Sir J. REMNANT: Is it not a fact that the cost of the London inquiry has been definitely fixed and levies have been made on the authorised undertakers for repayment?

Mr. NEAL: No, sir, certainly not.

Electric Power Charges.

In the House of Commons last Thursday, replying to Lieut.-Col. ARCHER SHEE, who asked the Parliamentary Secretary to the Ministry of Transport if he would state why the charge for electric power supplied by the County of London Electric Supply Co. still remained at 1½d., plus 90 per cent., in view of the reduction in the cost of material and labour, and whether he was aware that there was a general feeling of dissatisfaction among the consumers of this company's electricity owing to the fact that the high cost was detrimental to the revival of trade, Mr. ARTHUR NEAL said the Electric Lighting Orders under which the company was authorised to supply electricity fixed the maximum price which might be charged to consumers. The price mentioned in the question was within such maximum. He had no knowledge as to any general feeling of dissatisfaction.

Empire Wireless Scheme.

Mr. PIKE PEASE (Assistant Postmaster-General), in reply to Mr. Hurd (House of Commons, June 20), said the British Post Office had no share in the arrangement made between the Australian Government and the Marconi Australian Wireless Co., except to the extent that the contract contemplated communication with a station in this country, and that for the erection of such a station the co-operation of the British Post Office in some form or other was necessary. The bearing of the contract upon the Empire wireless scheme was under the consideration of the Government. The Canadian Government would shortly send two technical representatives to discuss the scheme with representatives of his Majesty's Government, and after these discussions had taken place it would be possible to describe the relationship of Canada towards the Empire wireless scheme.

Water Power Undertakings.

Mr. MILLS asked the Parliamentary Secretary to the Ministry of Transport (House of Commons, June 20) whether, in view of the continued problem of unemployment and consequent unproductive expenditure on unemployment pay and local relief, he would reconsider his decision not to proceed with the recommendations of the Water Power Resources Committee appointed to consider the utilisation of water power for electrical generation?

Sir W. MITCHELL-THOMSON, who replied, referred the questioner to the answer given to the hon. Member for the New Forest Division (Mr. Perkins) on March 13, but added that legislative authority had recently been obtained in one case, and in two other cases was being sought in the present Session by the promoters of water power undertakings.

Monte Video Trams.

In the House of Commons last week COLONEL NEWMAN asked the Under-Secretary for Foreign Affairs whether he had been successful in his efforts to obtain for the British-owned tramway undertaking at Monte Video the return of its property and funds sequestrated some time back by the national or local authority.

MR. HARMSWORTH (in reply) said that since the date of the hon. member's last question on this subject the Bill for the increase in tariff on the tramway had passed the Chamber of Deputies and gone up to the Senate. The appeal of the company against the action of the municipality was now before the Uruguayan Courts. Pending a decision of the Senate in the one case and the Courts in the other, representations by H.M. Government would be out of place.

Electricity Orders Confirmed.

On the motion of Mr. NEAL (Parliamentary Secretary, Ministry of Transport), the Special Order made by the Electricity Commissioners under the Electricity (Supply) Acts, 1882 to 1919, in respect of the parishes of Anlaby, North Ferriby, Melton, Welton, Waudby, Swarland, Willerby, Halternprice, Kirkella, and Westella, in the rural district of Sculcoates, in the East Riding of the County of York, and for the amendment of the Kingston-upon-Hull Electric Lighting Act and Orders, 1890 to 1915, was approved on Friday.

Private Bills.

The Court of Referees of the House of Commons have allowed a *locus standi* to the Aberdare and Aberaman Consumers Gas Co. and other gas companies to oppose the Bill of the SOUTH WALES ELECTRICAL POWER DISTRIBUTION CO., which confers further capital and other powers upon the company.

Electrical Vehicles for Municipal Work.

An interesting discussion took place at the annual conference at the INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS at Cardiff on Friday on a paper by Mr. R. B. MITCHELL, electrical engineer to the Glasgow Corporation, entitled, "Electric Vehicles for Municipal Work."

Mr. E. J. ELFORD, Cardiff, the newly-elected president of the Institution, was in the chair, and Mr. W. J. STEELE, Newcastle, opened the discussion. Mr. Steele contended that whilst electrical vehicles proved the best in certain districts, over long distances they were not so useful as steam. In an experiment over six months they found that steam was slightly cheaper than petrol.

Mr. H. G. WHYATT, Grimsby, said he noticed that Mr. Mitchell did not think that for Glasgow electric vehicles were an advantage over horse vehicles. His experience in Grimsby was that they saved 2s. 7d. per ton by using electric vehicles. These vehicles were bought about 18 months ago, and the total cost of collecting by them was 8s. 11¾d. per ton, whilst by their own horses the cost was 11s. 6¾d., and by other horses which they hired, 6½d. per ton more.

Mr. J. A. DAWES, Inspector of Cleansing, Ministry of Health, mentioned that his data showed that up to a distance of a mile the horse vehicle was quite satisfactory, but after a mile, especially where they had what was called kerb collections, the electric vehicles were cheaper. For longer distances the heavier vehicle answered best, and for distances of three miles or more steam was to be preferred.

The PRESIDENT was of the opinion that they could not get a proper basis of comparison if they put one vehicle on a short distance and another on a longish haul with different kinds of refuse. He thought the loading line was a very important question, and that many of the standard vehicles of the manufacturers were a good deal higher than they need be.

Mr. Mitchell was not present to reply to the discussion, but wrote stating that he would be pleased to supply any member with whatever information he had in his possession.

During the conference demonstrations of a number of electrically-driven appliances were given.

Legal Intelligence.

Welding Patent Litigation.

Last week Mr. Justice Eve heard a somewhat unusual action brought by Weldrics, Ltd., against the Quasi Arc Co., Ltd., for an injunction to restrain defendants from threatening them by means of circulars, advertisements or otherwise with legal proceedings or liability in respect of falsely alleging infringements of patent rights, of which defendants claimed to be the owners or were interested in. Defendants denied there was any threat to plaintiffs.

Sir Duncan Kerly, K.C., and Mr. C. Terrell appeared for plaintiffs, and Mr. J. Hunter Gray, K.C., and Mr. J. Whitehead for defendants.

In opening plaintiff's case, Sir Duncan Kerly said defendants had not suggested that plaintiffs had infringed their patents. Their case, in reply to the plaintiffs' charge of threats, was that there was no threat, but only a warning. Both plaintiffs and defendants made welding electrodes. In that case the electrode weld was covered with asbestos. Defendants were possessed of certain patents, but so far as the present case was concerned only one of them was of importance. That was a patent which was an improvement on an earlier patent. The original patent was that the electrode should be laid out for the purpose of welding along a groove. By way of improving it the patentee said he had discovered that the better way was, instead of putting it in a groove, to put it on an incline and that the covering should be of blue asbestos fibre. The first patent to be referred to was 1 274 of 1912, and the later one was 11 079 of 1912, which amended the previous one with a view to reducing the oxidising of the metal. Some time after this defendants commenced an action against a Mr. Scott Anderson and as the result of negotiations he elected not to defend the action, which came on undefended. Defendants obtained a judgment against Mr. Anderson which counsel contended was too wide in its terms. They got an injunction against Anderson restraining him from infringing the patent or from selling "any metal electrode covered wholly or partly with blue asbestos." These last words, counsel said, were quite unnecessary. Having got the injunction defendants proceeded to issue circulars to the trade in which they stated that all electrodes covered with blue asbestos were infringing patents held by them. This, later on, came to the knowledge of plaintiffs, and it was seriously interfering with their business. There were only a few firms engaged in making asbestos covered electrodes, and at least one firm was "bluffed" by defendants' circular and they ceased manufacturing them. In July, 1921, plaintiffs, having heard of the circular, wrote to defendants asking whether their electrode infringed the defendants' rights, and the latter having seen samples replied that plaintiffs' covering material appeared to be applied as a paste and in their view did not interfere with their patent rights. In November, 1921, however, defendants wrote to the Rose Street Foundry and Engineering Co., of Inverness, enclosing a copy of the circular and pointing out they were using blue asbestos. The Rose Street Co. were plaintiffs' manufacturers and their case was that this amounted to a threat against them of legal proceedings in connection with defendants' patents.

Mr. Samuel H. Gordon, of the Rose Street Foundry, gave evidence of the receipt of the letter enclosing the circular of which plaintiffs complained.

Mr. Andrew Stewart, a director of the Pneumatic Consolidated Tool Co., said the company proposed to take up an agency for plaintiff's goods, but learning of the circular about the blue asbestos he was unable to do business with them.

At the close of plaintiff's evidence, Mr. C. Terrell suggested that the sending of the letter and circular to the Rose Street Co. was intended to frighten plaintiffs, as defendants must have known the company were making plaintiffs' electrodes, and that amounted to a threat, as alleged in the action.

Mr. J. Hunter Gray, K.C., who opened the case for defendants, said he was of opinion the warning issued by defendants had overstated what was the judgment against Anderson, and he had advised his clients to modify it. They did not propose to send out any similar statements in that form. Those remarks, however, did not prejudice defendants in the present action, and he submitted that plaintiffs had no cause of action, and, further, that the circular was in no sense a threat, but a general warning to the trade.

Mr. Charles Henry Champneys, chairman and joint managing director of defendant company, stated that the Rose Street Company were customers of defendants, but he was not aware till the correspondence in connection with the action that there was any working connection between them and plaintiffs. In cross-examination (by Sir Duncan Kerly), witness said he thought he had the sole right to use blue asbestos. He was inclined to say he had a monopoly in the use of blue asbestos.

After further evidence was given, his Lordship, in giving judgment, said the case presented a great deal of difficulty. The facts were not really in dispute. In 1921 plaintiffs discovered it was possible to utilise blue asbestos after pulverisation and making it into a paste for the purpose of covering electrodes. Defendants got to know that these were being put on the market, and in July of that year plaintiffs took a strong but perfectly straightforward course by writing asking if they were infringing defendants' patent. Eventually defendants wrote that the paste did not come within the scope of their patent rights, not knowing that the paste was made of blue asbestos. Later in the year they found that the Rose Street Co. were dealing in blue asbestos, but did not know that company were intimately associated with plaintiffs. The result was the defendants wrote that the paste was not an infringement, but if blue asbestos was used they would stand upon their rights and take proceedings. Under those circumstances, his Lordship said he did not see how it was possible to hold that plaintiff company were aggrieved. The circular was a general warning that they intended to assert their rights if there was any infringement of their patents. The action failed, and would be dismissed with costs.

Postmaster General v. Liverpool Corporation.

The Court of Appeal (Lords Justices Bankes, Scrutton, and Atkin) delivered their reserved judgment on Monday upon the appeal of the Liverpool Corporation from a judgment of a Divisional Court reversing a decision of the Liverpool County Court judge who had found against the Postmaster-General upon his claim against the Corporation for the agreed cost (£40 8s. 7d.) of repairing damage done to the Post Office telephone plant by an electric light main belonging to appellants.

The electric light cable had been laid in 1889, enclosed in an iron cable. The telephone wire, laid in 1903, was in an iron pipe, and was adjoining and underneath the electric cable On August 6, 1918, there was an escape of electric current causing an explosion, which damaged both the electric light cable and the telephone wire. Contrary to the views expressed by the County Court judge, the Divisional Court held that both on the ground of nuisance and on the ground of debt the Postmaster-General was entitled to succeed, and from this result the Corporation appealed.

Lord Justice Bankes, in giving judgment allowing the appeal, after setting out the facts and referring to the material statutory provisions cited during the arguments, said that upon the facts the Postmaster-General could not, in his opinion, occupy any other position in regard to the telephone wire than that of a mere licensee. He thought, therefore, that he could not succeed in his claim. Having regard to the finding of the County Court judge the Postmaster-General must be regarded as a licensee with knowledge of the facts and of possible damage from the electric main. The damage arose from deliberately putting the telephone cable in immediate contact with the electric main. For these reasons he thought the appeal must be allowed, with costs there and below, and the judgment of the County Court judge in favour of the Corporation restored. (Lord Justices Scrutton and Atkin concurred.)

Electric Lamp Patents.

Last week Mr. Justice Astbury heard a motion on behalf of the British Thomson-Houston Co. for judgment in four actions in respect of patents. The defendants were H. Bake and Co., Childs Thomann, and the Empire Electric Lamp Co.

Counsel said the judgment was drawn in the usual form, and his Lordship gave judgment for plaintiffs, as asked.

Personal and Appointments.

Alderman Hamilton has retired from the chairmanship of the Preston Electricity Committee.

The Council of the University of Leeds has appointed Dr. W. T. David, M.A. Cambridge, D.Sc., Wales, to be Professor of Civil and Mechanical Engineering, and to take up his duties next October on Prof. Goodman's retirement from the chair.

Mr. E. B. Pausey has resigned his appointment as power station superintendent at the Loughborough Corporation Electricity Works, having accepted a similar appointment at the Poulton power station of the Wallasey Corporation.

Readers of The Electrician will be interested to learn that The Metropolitan Electric Supply Company have appointed Major H. Richardson, O.B.E., M.C., Manager of the Electricity Undertaking of the Dundee Corporation, as General Manager of the Company in succession to Mr. W. R. Rendell, who has resigned on account of ill health. Major Richardson will take up his duties on 1st October next.

Sub-Station Fire on Metropolitan Railway.

A fire broke out at about 6.30 on Sunday evening at the Metropolitan Railway Company's Moor Lane sub-station, and did damage estimated at about £100 000. Traffic on the Metropolitan line from Aldgate to Baker Street, and on the Great Northern and City Railway from Moorgate to Finsbury Park was stopped during Sunday night, but was resumed on Monday.

We are informed that the fire was due to an internal short circuit in one of the transformers. The oil became ignited, burnt through the tanks and set fire to the building. There is no foundation for the statements in some of the daily papers as to overloading being the cause.

On the West Ham Borough electricity account there is a surplus for the year of £23,472.

Electricity Supply.

The Ministry of Transport has revoked the DEAL AND WALMER Electricity Order held by the Gas Co.

As from July 1 the charges for electricity at MANSFIELD are to be reduced from 150 per cent. to 100 per cent. above pre-war prices.

PRESTON Electricity Committee has decided to charge half lighting rates to private users of electricity for the decorations during Guild week.

EXETER City Council has reduced the charges for electricity by $\frac{1}{8}$d. per unit and the charge for power to the tramways from $2\frac{5}{8}$d. to $2\frac{1}{4}$d. per unit.

HEMEL HEMPSTEAD Rural Council has consented to an application by Watford Urban Council for an Order to enable them to supply electricity to Kings Langley and Bovingdon.

BARNSTAPLE Town Council have received a letter inquiring whether they are prepared to consider negotiations for the sale of the Corporation Electricity Works. A special meeting is to be held to consider the proposal.

DOUGLAS (ISLE OF MAN) Town Council has accepted the offer of the Manx Electric Railway Co. for electricity for the decorative lighting on the front up to September 30 at $6\frac{1}{4}$d. per unit up to 11 p.m., and 9d. per unit after that hour.

NORWICH Electricity Committee announce a reduction in the charges for electricity as from July 1. This will leave the advance in the charge for power at 50 per cent. above pre-war instead of 100 per cent., and bring the charge for lighting in combination with the assessment charge to 1d. per unit. The committee also propose to reduce the charge for public lighting from £3 per lamp per annum to £2 15s. The number of public lamps is 2 627.

At a meeting of the FAVERSHAM Town Council, on June 20, Councillor Clark proposed that the municipal electricity undertaking should be disposed of, on the grounds of the cost to the ratepayers, the deficiencies aggregating upwards of £17 000 in 17 years, and that a large capital expenditure was necessary to put cables in order. It was stated that £14,133 had been repaid off loans, and that the largest loan of £18 000 would be repaid in six years. The motion was defeated by 6 votes to 4.

HAMMERSMITH Borough Council have received the formal sanction of the Electricity Commissioners to the borrowing of (*a*) £17 735 (on account of £27 000), in connection with the supply of electricity to the Wormholt Housing Estate, repayable as to £15 155 (mains and services) within 25 years, £420 (switchgear) within 20 years, and £2 160 (meters) within 10 years; (*b*) £16 894, for general main extensions, etc., repayable as to £8,494 (mains and services) within 25 years, £5 423 (transformers, etc.), within 20 years, and £2 977 (meters) within 10 years.

For some time past the Light Railways and Electric Lighting Committee of SOUTHEND Town Council have been considering alternative schemes to meet the future demands for electricity in the town. At their meeting last week they decided to recommend the Council to adopt the scheme submitted by the consulting engineer, Mr. C. H. Wordingham, who advocates the generation of electricity by means of turbo-alternators, the scrapping of the existing works in London Road, and the sub-stations, and the establishment of a generating station on a site outside the borough. The estimated cost of the scheme is £409 000. The alternative scheme recommended by the borough electrical engineer (Mr. R. Birkett) recommends the continuance of the present works, and the installation of additional Diesel plant, at an estimated cost of £240 000. A special meeting of the Town Council is being held this week, when the report and recommendations of the Committee will be considered.

Business Items, etc.

ELECTRIC LAMP FACTORS, LTD., have removed to larger premises at 44, Berners Street, London, W. 1. Telephone: Museum 6886.

Mr. ROBERT LEACH has been appointed sales engineer to FERGUSON, PAILIN LTD., for Lancashire, Yorkshire and North Wales areas.

It is announced that HEAD WRIGHTSON AND CO. have taken over the interest of the amalgamated industries in Whitwell and Co., Ironworks, Thornaby.

F. W. PARKES AND CO. announce that they have removed from 65, Dame Street, Dublin, to larger premises at Faraday House, Temple Lane, Dame Street.

RADIO INSTRUMENTS, LTD., announce that the address of their company is 12A, Hyde Street, New Oxford Street, W.C.1, not 18A, Hyde Street, as stated in our issue last week.

The Birmingham sales office of CALLENDER'S CABLE AND CONSTRUCTION CO. is now at Daimler House, Paradise Street, Birmingham. The company's representative at this office is Mr. J. M. Dunkeley.

The business offices and manufactory of the BRITISH CLIP CO., makers and patentees of the "Whippet" Clip, have been transferred to more central premises at 146, Blackfriars Road, S.E.1, to which address all communications should be sent.

Electric Traction.

By 52 votes to 28 GLASGOW Town Council last week decided to offer £250,000 for the purchase of PAISLEY District Tramways Co.

HAMMERSMITH Borough Council recommend that the original penny fare stages on the London United Tramways system be reintroduced.

DEWSBURY Town Council has applied to the Ministry of Transport for an extension of two years for carrying out the work authorised by the Tramways Order, 1911.

The WESTON-SUPER-MARE and District Electric Supply Co., have applied to the Ministry of Transport for an extension of time until August, 1924, for the completion of the tramways authorised by the order of 1900.

After fully considering the position with regard to the tramways, trolley 'bus, and motor-'bus undertakings of the Corporation Keighley Town Council have decided that for the present at any rate, a £40 000 scheme for the reconstruction of the tramway track must be shelved. An electric arc welding plant is to be purchased at an estimated cost of £316 for welding up tram rails where the foundations are good, also a rail grinder, at an estimated cost of £150. These steps are only palliative, and the bigger problem of dealing with those portions of the track which are in a very unsatisfactory state will have to be dealt with later.

With regard to the motor-'bus and trolley-'bus services the Council is faced with a serious position, due to the heavy losses of the trolley 'busses, caused largely by constant failures of the mechanism. The tramways department have, it is stated, at least half a dozen vehicles which are not fit to run at the present time, and the repairs have not been worth the money spent upon them. The greatest difficulty has been with regard to the motors, which are an integral portion of the rear wheels, but now the committee has obtained the sanction of the Council to carry out a conversion from the present wheel drive to a back axle drive, the cost being estimated at £525.

The HULL members of the Tramwaymen's Union are greatly disturbed at the proposals of the Corporation Economy Committee. These have not yet been publicly disclosed, but it is understood that a sum of £30,000 is to be saved. At a meeting held on Friday a resolution was passed by which the men pledged themselves to resist to the uttermost any attempt to economise at the expense of the men employed in the undertaking, which would obviously curtail the efficiency of the service, and in turn cause the public further inconvenience. The meeting also discussed the competition of motor 'buses with tram cars, and it was suggested that privately-motor-owned 'buses should not be licensed by the Corporation, unless the persons employed on such vehicles are working under trade union conditions as to pay and hours. The tramwaymen were advised that they had no power to enforce this; but they passed a resolution, pointing out that with proper tramway organisation private 'buses could not carry passengers within the city boundaries.

Wireless and Telegraph Notes.

At the request of the German Chamber of Commerce at COLOGNE, the postal authorities have agreed to the appointment of officials at the main Cologne telegraph office who have a thorough knowledge of French and English.

A Reuter's message from New York states that Signor Marconi has announced the invention of a WIRELESS SEARCHLIGHT, by which wireless waves, reflected like light waves, may be sent in any direction in a beam instead of being scattered in all directions.

Considerable acceleration of the commercial wireless service between ENGLAND AND SPAIN has been secured by the recent transfer of this service from the Poldhu station to a new Marconi station at Ongar. Under the new conditions messages to Spain, marked "via Marconi," instead of being relayed by long land line circuits to Cornwall are transmitted direct by distant control from Rio House, London, to the receiving station in Spain.

American data is now added to the COLLECTIVE EUROPEAN WIRELESS WEATHER REPORT which is transmitted daily at 11.30 a.m. (Greenwich Mean Time) from the Eiffel Tower. The observations circulated consist of the reading of the barometer and the direction and force of the wind at 1 a.m. (G.M.T.) on the day of issue at about thirty places scattered over the Continent, including Bermuda, Chicago, Cleveland, Denver, Cape Hatteras, Salt Lake City, San Francisco, Washington, and Winnipeg. Approximate positions of the centres of cyclones and anticyclones are also indicated.

On July 24 the EASTERN ASSOCIATED TELEGRAPH COMPANIES will celebrate the FIFTIETH ANNIVERSARY of their incorporation at a banquet and fete, to be held in the gardens of the Royal Botanical Society, at which the Duke of York has promised to be present. The staffs of the companies are marking the occasion by a presentation to the chairman, Sir John Denison-Pender, of a bound volume containing the signatures of nearly 8 000 subscribers, and the reproduction in platinum, set with brilliants, of the Stars of the Insignia of the Orders of K.C.M.G. and G.B.E. In addition they are permanently endowing a bed in St. Bartholomew's Hospital to the memory of Lady Beatrice Katherine Denison-Pender (the chairman's late wife).

Miscellaneous.

The J. S. Fry and Sons, Ltd. Colston Research Fellowship, which provides for payment of fees and a maintenance allowance of £150 a year, at Bristol University, has been awarded to Mr. Francis Baliol Wrightson, a student in the Faculty of Engineering.

The District Industrial Council for Electricity Supply Industry (West Midlands area) notifies a further reduction of a halfpenny per hour in the wages of employees as from July 1 next. The revision is based upon the average of the cost of living figures for the three preceding months, the agreement providing that there shall be an increase or decrease of one half-penny per hour for every completed six points variation. The average of the figures for April, May and June shows a decrease of nine points.

We are asked by the Institute of Physics to mention that a great many persons who have received a copy of the preliminary number of the proposed Journal of Scientific Instruments, and who may wish to support it have not yet filled in the form inserted in the Journal. It is hoped that all who intend to subscribe will inform the Institute without delay so that an estimate may be formed of the support which may be relied upon. Sufficient support must be forthcoming before it is possible to issue the Journal.

A new scheme for the development of British chemistry and science has been put forward by Sir William Jackson Pope, Prof. of Chemistry at Cambridge University. He proposes the immediate establishment of an Advisory Science Committee to the Board of Trade. Extravagance and muddling could be saved once and for all, he maintains, by the establishment of an advisory body of about twelve scientific and chemical experts, which would meet at stated intervals and give expert guidance to the Government in all matters concerning the nation's scientific welfare. As it would not be a part of the Government machine, the cost of maintenance would be negligible, and the saving it could effect in national expenditure would be incalculable.

Companies' Meetings, Reports, etc.

Shropshire, Worcestershire and Staffordshire Electric Power Co.

The ordinary general meeting of the Shropshire, Worcestershire and Staffordshire Electric Power Co. was held on June 22, at Electrical Federation Offices, 88, Kingsway, W.C., Mr. Wm. L. Madgen (chairman and managing director) presiding.

The chairman, in moving the adoption of the report and accounts, said that a great change had recently taken place in connection with electric supply undertakings. When most of the undertakings were established, a few years before the beginning of the present century, there was a marked difference between distribution companies and power companies. Whereas distribution companies were liable to be purchased by the local authorities after a term of years, usually about 22 years—20 of which had already elapsed—power companies had a perpetual tenure and were not subject to expropriation. It was now to be observed that the progress of electric supply although very slow to commence, had during the past few years undergone a remarkable change, both in the use for power and for domestic purposes.

Past Year's Working.

With regard to their own company, the volume of business done and the net profits obtained during the year 1921 had not been so large as in the previous year. The obvious explanation was that the coal strike had suspended industrial operations and inaugurated a severe depression in trade generally. The figures for the past year were better than those for 1919, but they expressed only a small part of the improvement that had taken place. The sale of electricity for power purposes was in their area an accurate barometer of the general state of trade; therefore they were probably dependent to a larger extent for their profits on general industrial conditions than many other electricity supply undertakings. This was brought out very clearly by the number of potential consumers on their mains. During the last few years they had connected up a large number of new consumers, and old consumers had increased their equipments for the employment of electricity; there was a larger potential demand on their generating plant than at any previous period. But notwithstanding all this, the output of electricity from the company's generating station at the present time was only about 50 per cent. of the generating plant installed, showing clearly that the prosperity of the company was very largely dependent upon the state of trade in the district.

Improved Financial Position.

A comparison of the balance sheet now presented with the preceding balance sheet showed a marked improvement in the financial standing of the company. They had paid off many of their liabilities; had improved their reserves and increased their available cash resources. They had been enabled to do this by the issue made during the past year of £300 000 7½ per cent. ten-year guaranteed convertible debenture stock. The issue was oversubscribed, and had enabled the company to put its finances on a satisfactory basis. The loan from the Ministry of Munitions had been reduced by the agreed annual instalment of £13 066, which made with previous instalments a total amount repaid of £62 867, leaving a balance outstanding and repayable by annual instalments during the period of twenty years from 1921 of £257 133. The reserve fund now stands at £86 310, after applying the amount appropriated from the sinking fund under the first debenture trust deed.

A sum of £48 617 was expended during the past year upon buildings, plant, machinery and mains. They had, however, about reached the practical limit of extensions on the site of their power station at Smethwick, and contemplated that their further requirements would have to be met by means of an additional power house of considerable magnitude at Stourport on the River Severn.

The S.W. Midlands District.

During the past year an inquiry had been held in the district by the Electricity Commissioners for the delimitation of the company's area with a view to the constitution of a joint electricity authority for the district.

The company, in association with the city of Birmingham, had made an alternative proposal to the effect that an advisory committee should be constituted to administer the supply in the South-west Midland area, including a portion of their own statutory area and of the Parliamentary area of the city of Birmingham. The Commissioners had acceded to that suggestion. If the scheme was confirmed at a second inquiry, to be held on the 29th inst., it would probably be put into effect immediately after the passage of the Electricity (Supply) Bill now before Parliament. Application had been made to the Treasury to guarantee the expenditure involved for the erection of the above-mentioned power station on the Severn, and a decision might shortly be expected, in which case a meeting of the shareholders would be called to authorise the constitution of the undertaking of the power-house as a separate undertaking.

The report and accounts were adopted.

The General Electric Co. (of New York) announce a dividend of 2 per cent. on capital stock, payable on July 15.

At a general meeting of the Allgemeine Elektricitats Gesellschaft last week, it was decided to increase the capital by an amount up to 250 000 000 marks.

The directors of the India Rubber Gutta Percha and Telegraph Works announce that they are unable to recommend an interim dividend on the ordinary shares.

After providing for interest on and redemption of debentures the accounts for 1921 of the Lisbon Electric Tramway Co. show a loss of £29 184, which increase the debit carry forward to £48 455.

The directors of the Eastern Extension Australasia and China Telegraph Co. have declared an interim dividend for the three months ended March 31 last of 5s. per share, payable free of income tax, on the 15th prox.

Edgar Allen and Co. report a net profit for the year of £25 238. The directors propose a final dividend on the ordinary shares of 6d. per share, making 5 per cent. for the year, tax free, carrying forward £20 067, compared with £30 240 brought in.

The directors of the Metropolitan-Vickers Electrical Co. announce their intention to increase the sinking fund for the redemption of the six per cent. prior lien debentures by setting aside this year the additional sum of £131 233, and that the whole of the above-mentioned debentures will be paid off at par on January 1st, 1923.

The Eastern Telegraph Co. announce the payment on July 15, of dividend at the rate of 3½ per cent. per annum less income tax on the preference stock of the company for the quarter ending June 30, 1922, and a first quarterly interim dividend of 2½ per cent. on the ordinary stock, free of income tax, in respect of profits for the year ending December 31, 1922.

Subscriptions are now invited for the expected issue of £2 500 000 in 4½ per cent. second debenture stock by the Underground Electric Railways. The loan, £1 000 000 of which is on behalf of the London Electric Railway and £1 500 000 for the City and South London Railway, is issued at £94, and is guaranteed as to principal and interest by the Government under the provisions of the Trade Facilities Act. The proceeds of the issue will be applied towards the construction and equipment of the Edgware and Hampstead Railway, forming an extension from the terminus of the section of the London Electric Railway at Golders Green to Hendon and Edgware, the construction of connecting railways at Camden Town to enable a through service of trains to be worked between the City and South London Railway and the London Electric Railway, the enlargement of tunnels and improvement of stations on the City and South London Railway, and the provision of new rolling stock and equipment.

The profit of J. G. White and Co. for the year ended February 28 last was £11 154, plus £13 193 brought in, making available £24 347 which has been used in pursuance of the scheme for reduction of capital. The nominal capital was reduced from £500 000 to £350 000 by writing off from each of 200 000 issued ordinary shares of £1 each the sum of 15s. per share. The sum of £150 000 was written off from the debt due by J. G. White Commercial Co. and £100 000 has been received from that company in cash, reducing the balance of its debt to £84 000. Investments now stand in the books at £304 887, after deduction of reserve of £50 000, balance on profit and loss account above-mentioned, and £5 149 available on revaluation of office furniture, plant and instruments, making total deduction of £79 497. As a further part of the scheme for the reduction and reorganisation of capital, 50 000 of unissued ordinary shares of £1 each were sub-divided into 200 000 ordinary shares of 5s. each, and these shares, since the date of the balance sheet, have been allotted at par. Preference shareholders have accepted the arrangement waiving their cumulative rights for a period of three years ending August 31, 1923.

H

Tenders Invited and Accepted.

UNITED KINGDOM.

Gellygaer Urban Council, July 4.—Transformer plant, e.h.t. and l.t. switchgear, steel poles, h.d. copper wire, cable and boxes, etc. Specifications from the Electrical Engineer and Manager, Bargoed.

Wimbledon Corporation, July 10.—Four 1 000 kVA, 10 000/2 000 V transformers. Specification from the Borough Electrical Engineer.

Torquay Corporation, July 12.—One 3 000 kW turbo-alternator and condensing plant. Specification, etc., from the Borough Electrical Engineer.

Navan Urban Council, July 12.—D. c. main switchboard, d.c. generators, mains, oil engine set, house service meters and fuses, public lighting fittings and brackets, lamps, cables, insulators, etc. Specifications from Mr. J. J. Woods, Clones, co. Monaghan.

Connahs Quay Urban Council, July 14.—Sub-station equipment, overhead and underground mains, public lighting, etc. Specifications from Mr. A. J. Leigh, 122, The Albany, Old Hall Street, Liverpool.

Gravesend Corporation, July 17.—Five thousand kW turbo-generator, condensing plant, switchgear, mains, artesian well and automatic stokers. Specifications from the Borough Electrical Engineer.

London County Council. July 24.—H. T. Switchgear at the Central Repair Depot, Charlton. Particulars from the Clerk of the Council, County Hall, Westminster Bridge, S.E.1.

London County Council, July 31.—Four electric lifts for the Council's tramways central repair depot, Charlton. Particulars from the Clerk of the Council, County Hall, London, S.E.1.

Dublin Corporation, August 1.—Two sets of electrically-driven sewage pumps, each capable of dealing with 18 million gallons per day. Specifications from the City Engineer or Mr. J. S. Alford, 11, Victoria Street, Westminster, S.W.1.

AUSTRALIA.

Postmaster-General's Department, Brisbane, August 9 *—Protective apparatus (Stores Schedule No. 563)

Postmaster-General's Department, Perth, August 9* :—Telephone and telegraph apparatus, testing instruments, and protective apparatus (Schedule No. W.A. 734).

Commonwealth of Australia, August 22.—Silk and cotton-covered switchboard cable (Schedule 35). July 25.—Paper-insulated and lead-covered submarine cable (Schedule 42). October 17.—Automatic c.b. telephone equipment (Schedules 39 and 40). August 9.—Protective apparatus (Schedule 563). Specifications, etc., from the Supply Officer, Room 101, Australia House, Strand, London, W.C.

INDIA.

High Commissioner of India, July 21.—(1) Automatic telephone sets, desk and wall; (2) cards for telephone switchboards, etc.; (3) cells of various descriptions for accumulators. Particulars from the Director-General, India Store Department, Belvedere Road, Lambeth, S.E.1.

Hammersmith Borough Council have accepted the tender of the Clay Cross Co., for a "Green" economiser at £1 550.

Barnes Urban Council have accepted the tender of the Pirelli General Cable Co. for 1 750 yd. of cable, £520.

Hebburn-on-Tyne Electricity Committee recommend the Council to accept the tender of A. Reyrolle and Co. for nine e.h.t. panels, £3 100.

Ayr Corporation have accepted the tender of Callender's Cable and Construction Co. (lowest tender of two received), for cable to Allaway, at £4,791 0s.

Doncaster Town Council has accepted the tender of Babcock and Wilcox, Ltd., for two water tube boilers, with economisers, induced draught plant, and steel chimney, at £21 663.

Rugby Urban Council has accepted the tender of W. T. Henleys Telegraph Works Co. for 1 050 yards of l.t. three-core cable; and that of the British Thomson-Houston Co., for three transformers.

Dover Corporation have accepted the tenders of Callender's Cable and Construction Co. for service cables for Carr House, Arksey, at £685 19s. 8d.; and Johnson and Phillips for e.h.t. switchgear, £96.

Douglas, I.O.M. Electricity Committee has decided to accept the tender of Siemens Bros. and Co. for lighting equipment at £8 237, subject to the consent of Tynwald being obtained to borrow the money.

London County Council have accepted the tender of E. Bennis and Co. (lowest complete tender received) for an ash conveyor for Greenwich power station at £2 874 18s. (10 complete tenders received; highest £6 164); and the same firm's tender for an ash hopper at £2 409 (13 complete tenders received, varying from £1 989 to £3 277).

* Particulars from the Department of Overseas Trade.

Glasgow Corporation are recommended to accept the following tenders for plant required at the Provan Chemical Works:—Bruce Peebles and Co., 60 h.p. totally-enclosed motor; McFarlane Engineering Co., 10 h.p. ditto; J. Bennis, Ltd., 15 cwt. electric-driven lime and ash hoist; Paterson Hughes Engineering Co., electric crane; W. Weir, electric lighting work of Blackfriars Church (£252).

Sunderland Corporation have accepted the following tenders:—Steel, Peech and Tozer, tramway rails; Ferranti, Ltd., 108 d.c. meters; Pirelli General Cable Works, l.t. cable; Consolidated Pneumatic Tool Co., electric blower; W. G. Allen and Sons, two ½-ton soot waggons; Callender's Cable and Construction Co., 7 a.c. disconnecting boxes, 9 d.c. disconnecting boxes; Henley's Telegraph Works Co., 1 feeder pillar.

Bradford Corporation have accepted the following tenders:—Cole, Marchent and Moreley, 20 tons brake shoes, £245; Reyrolle and Co., e.h.p. switchgear for two 1 500 kW motor converters at Bolton Road sub-station; Bertram Thomas, d.c. switchgear for two 1 500 kW motor converters; English Electric Co., 150 kVA special testing transformer; Metropolitan-Vickers Electrical Co., control gear for a.c. motors for No. 4 boiler-house, at Valley Road station; Landis and Gyr, Ltd., 600 single-phase a.c. house service meters; British Insulated and Helsby Cables, Ltd., overhead line from transformer chamber in Thornton Road to York Street.

Arrangements for the Week.

MONDAY, JULY 3rd.

Royal Institution of Great Britain.

5 *p.m.* At Albemarle Street, Piccadilly, London, W.1. General meeting.

TUESDAY, JULY 4th.

The Institute of Physics.

5.30 *p.m.* At the Institution of Electrical Engineers, Victoria Embankment, London, W.C.1. Lecture on "The Physicist in Engineering Practice." By Sir J. Alfred Ewing K.C.B., F.R.S.

SATURDAY, JULY 8th.

Electrical Power Engineers' Association (Derby and District Section).

5 *p.m.* At the Queen's Hotel, Bridge Street, Burton-on-Trent. Address on "Economy in Mains Laying," by Mr. T. A. G. Margary.

Prices of Metals, Chemicals, etc.

Sulphur (Flowers)—Ton £10 15s.

,, (Roll-Brimstone)—per ton £10 15s.

Sodium Bichromate.—Per lb. 5¼d.

Boric Acid (Crystals). Per ton £60.

Sodium Chlorate—Per lb. 3¼d.

Sulphuric Acid (Pyrites, 168°) per ton, £9.

Copper Sulphate.—Per ton £26 15s.

Rubber.—Para fine, 9¾d.; plantation 1st latex, 7¾d.

The metal prices are supplied by British Insulated & Helsby Cables, Ltd., and the rubber prices by W. T. Henley's Telegraph Works Company.

COMMERCIAL INTELLIGENCE.

RECEIVERSHIPS.

BROTHERTON EDISWAN TUBES AND CONDUITS, LTD.—R. H. Johnston, of 49, Queen Street, Wolverhampton was appointed receiver and manager on June 14th, 1922, under powers contained in debentures dated April 7, 1921.

REEVE AND BAYMAN, LTD.—E. H. Hawkins, of 4, Charterhouse Square, E.C., was appointed receiver on June 13th, 1922, under powers contained in first mortgage debenture dated December 7, 1921.

Mortgages and Charges on Limited Companies.

[NOTE.—The Companies Act of 1908 provides that every Mortgage or Charge, as described therein, created by a Company after the commencement of the Act, shall be registered within 21 days after its creation, otherwise it shall be void against the liquidator and any creditor. The Act also provides that every Company shall, in making its annual Summary under the Companies Act, specify the total amount of debt due from the Company in respect of all Mortgages or Charges which would, if created after the commencement of the Act, require registration. The following Mortgages and Charges have been so registered. In each case the total debt prior to the present creation, as specified in the last available Annual Summary, is also given—marked with an *—followed by the date of the Summary, but such total may have been reduced since such date.]

ELCO ELECTRIC MANUFACTURING CO., LTD., Bristol.—Registered June 15, £4 500 debentures; general charge. *Nil. February 22, 1921.

FELLOWS MAGNETO CO., LTD., London, N.W.—Registered June 16, £60 000 debentures; general charge. *Nil. August 12, 1921.

STELLA LAMP CO., LTD. (late Harlesden Lamp Co., Ltd.), London, N.W.—Registered June 14, £23 500 debentures; general charge. *——. February 17, 1921.

Private Meetings, etc.

[*Inclusion under this heading does not necessarily imply failure. Many private meetings are called merely for the purpose of the debtor consulting his creditors as to his position when he may not be insolvent.*]

W. WATKIN AND SON, LTD. (in voluntary liquidation), 181, Queen Victoria Street, London, E.C., electrical engineers, etc. At a recent meeting of the principal creditors, held prior to the company meeting to wind up, a committee was appointed consisting of Ashby and Sons, Grimwood and Co., H. P. Smith, Ltd., the National Radiator Co., and Woodworkers, Ltd. At the statutory meeting of creditors last week, Mr. A. Quaife, whose appointment as liquidator was confirmed, stated that an approximate statement of affairs presented at the preliminary conference showed that there were unsecured liabilities amounting to £10 903, while a partly secured creditor, the bank, claimed £765 17s. 8d. This creditor held a charge on certain contracts, valued at the same amount, which concerned an electrical job at Aldershot. He, the liquidator, had been going into the figures, and it was difficult to see how this job would work out, but the architect had recommended a payment of between £500 and £600 on account of the contracts, and the War Office, for whom the work was undertaken, had refused to pay a penny, because of the unsatisfactory nature of the work. With regard to the assets, he thought that if they produced in all something like £1 500, or at the very outside £2 000, it was as much as the creditors could expect to receive in the course of the realisation. The company was registered on April 12, 1921, with a nominal capital of £5 000, and the directors were Mr. Sandiford, Mr. Munro, Mr. Bearfoot, Mr. Lewis, and Mr. H. C. Wood. The object of the company was to take over the business of engineers which had been carried on by Mr. Sandiford. The misfortunes of the company seemed to have grown out of the fact that the business, which was originally connected with electrical and general engineering, etc., was extended to embrace building, and the unfortunate part was that this latter branch of the business was not sufficiently understood to enable the directors to cope with the contracts which were undertaken with any hope of success. It was not intended that the business should be in any way continued. The following are creditors: Baxter and Caunter, Ltd., £108; Butterfield, H., £257; Credenda Conduits Co., Ltd., £320; Farmiloe, Geo., and Sons, Ltd., £149; Fell, Anderson and Co., Ltd., £316; Grimwood and de Geus, Ltd., £520; General Electric Co., Ltd., £91; Henley's, W. T., Telegraph Works Co., Ltd., £46; Heywood and Bryett, Ltd., £306; Kartret Engineering Co., Ltd., £433; Morgan and Son, Ltd., £72; Fenwick, J. Owen and Son, £173; Sharman, P. R., £244; Watshams, £105; Woodman, G., £130.

London Gazette.

The following information is taken from printed reports, but we cannot be responsible for any errors that may occur.

Companies Winding Up.

HUBERT D. CARTER (BANGOR), LTD.—Voluntary winding-up to be continued, but subject to the supervision of the Court; G. G. Poppleton, of Birmingham, and A. T. Eves, of Manchester, appointed joint liquidators in place of W. R. Redwood.

Companies Winding-up Voluntarily.

CHASE, A., AND CO., LTD.—A. M. Cole, of Fairfax Road, Teddington, appointed liquidator.

TREDEGARS, LTD.—Norman Bell, of T. Fuller, Carter, Son and White, and B. B. McCallum, of Tansley Witt and Co., 5, Chancery Lane, W.C.2, appointed joint liquidators. Meeting of creditors at the Institute of Chartered Accountants, Moorgate Place, E.C., on Friday, June 30, at 12.30 p.m.

Bankruptcy Information.

GILL, Frederick John, 26, Hardwick Street, Buxton, electrical engineer. Receiving order, June 19. Debtor's petition.

HENSON, Leslie Rowland, 23, Greenlanes, Islington, London, electrical engineer. Receiving order, June 23. Debtor's petition. First meeting, July 6, 11 a.m., and public examination, July 28, 11 a.m., Bankruptcy Buildings, Carey Street, London, W.C.2.

WYNESS AND BALE, 13, Commercial Street, Brighouse, York, electrical engineers. Receiving order, June 23. Creditor's petition.

Notice of Dividend.

GOSS, Frederick Charles, 32, Windsor Road, St. Andrews Park, Bishopston, and 71, North Road, Bristol, electrical engineer. Amount per £, 2s. 6¼d. First and final. Payable, June 30, 26, Baldwin Street, Bristol.

Notice of Intended Dividend.

LUDLOW, Jesse Frederick, and LUDLOW, Robert Redvers, in co-partnership as LUDLOW BROTHERS, 196, Church Road, Redfield, Bristol, electrical contractors. Last day for receiving proofs, July 8. Trustee, F. W. Darley, 36, Baldwin Street, Bristol.

LIDDELL, Robert Henry, under the name of LIDDELL AND McINNES, 4, The Crescent, Carlisle, electrical engineer Last day for receiving proofs, July 14. Trustee, K. J. Hough, 34, Fisher Street, Carlisle.

Dublin Gazette.

Notice is given, that the partnership between BRABANTS, Jules and O'CALLAGHAN, John, electrical and mechanical engineers, 16, Queen Street, Cork, under the style of BRABANTS, O'CALLAGHAN AND CO., has been dissolved by mutual consent, as far as regards J. Brabants. Debts received and paid by J. O'Callaghan, who will continue the business under the present style.

Bankruptcy Proceedings.

ROTHWELL, Herbert, WATSON, Stanley James, and JINKS, Francis Cecil (sued as the VULCO MAGNETO CO.), 11, Long Acre, W.C. In this bankruptcy the Official Receiver has now issued to the creditors a summary of the debtors' joint statement of affairs, which discloses ranking liabilities £2 076, and assets nil. The separate estate of the debtor Watson shows liabilities £34 775, of which £10 317 are expected to rank, and estimated net assets £2 793. In his observations the Official Receiver reports that the debtor Watson has stated that in May, 1910, he was appointed sole representative and agent in the United Kingdom for a German company carrying on business as manufacturers of electric parts, magnetos, etc., and on the outbreak of the war he assumed the proprietorship of the business. In the early part of 1915 he took premises at 37, Sheen Road, Richmond, for the purpose of manufacturing electrical goods required for war purposes. The debtor Rothwell states that in January, 1918, he and another person began business at 11, Long Acre as electrical and mechanical engineers, and carried it on under the style of the Vulco Magneto Co. In November, 1918, his partner retired, and the debtor then took into partnership the debtor Watson, who provided £700, of which £350 was treated as a personal loan. In May, 1919, they were joined by the debtor Jinks, who paid £800 for a one-third share in the business. The first year's trading, to November 30, 1919, produced a small profit, but the trading was afterwards conducted at a loss, and in October, 1920, Jinks severed his connection with the business, and the debtor Watson expressed his inability to provide further capital. The partnership then for all practical purposes came to an end, although no formal dissolution took place. The debtor Rothwell afterwards transacted, but in the name of the firm, what business was done, although he was mainly engaged in realising the firm's assets. Eventually a creditor who had obtained a judgment against the firm presented the petition on which the receiving order was made. The debtor Rothwell attributes the failure and insolvency of the Vulco Magneto Co. to lack of working capital to pay wages and other outgoings, to the firm's inability as a consequence, and also because of the non-delivery of necessary parts to complete certain work on hand, as a result of which there was a heavy trading loss, and to liabilities for breaches of contract and law costs. At a sitting of the London Bankruptcy Court last week, the public examination of the debtor Watson was adjourned and that of his late partners concluded.

Patent Record.

SPECIFICATIONS PUBLISHED.

The following abstract from some of the specifications recently published have been specially compiled by Messrs. Mewburn, Ellis & Co., *Chartered Patent Agents, 70 and 72, Chancery-lane, London, W.C.*

Complete Specifications.

173 878 Scott, J. L. Electrical contact makers for use with the steering-wheels of motor-vehicles. (9/10/20.) (Addition to 134 973.)
173 886 Igranic Electric Co., Ltd. (Cutler-Hammer Manufacturing Co.). Electric regulating systems. (12/10/20.)
173 889 Jhamuotila, K. R. Disposition of safety devices and connexions in multiphase or polyphase generators and other electrical apparatus. (12/10/20.)
152 352 Kominik, O., and Nossic, J. Electric fuses or cut-outs. (10/3/19.)
152 358 Pelizzola, M. Sparking-plugs. (14/10/20.) (Convention date not granted.)
173 905 Baker, P. W. Thermally-actuated electric switches. (18/10/20.)
173 916 Igranic Electric Co., Ltd., and Yerger, C. W. Control of electric circuits. (25/10/20.)
173 922 Railing, A. H., Garrard, C. C., and Wilson, W. Means for interlocking electric switches. (29/10/20.)
173 933 Schmidt, J. (Buckholtz and Co., A. R.). Electric torches for medical purposes. (3/11/20.)
173 934 British Thomson-Houston Co., Ltd. (General Electric Co.). Incandescent lamps. (4/11/20.)
173 948 Bassett, E. Electric iron for domestic purposes. (26/11/20.)
173 950 Fletcher, G. H., and Metropolitan Vickers Electrical Co., Ltd. Systems for controlling electric motors. (30/11/20.)
155 830 Veifa-Werke Vereinigte Electrotechnische Institute Frankfurt-Aschaffenburg, and Dessauer, Dr. F. High-tension electric transformers. (29/9/15.)
156 099 Vogeli, F. Apparatus with electric arrangement for the generation of steam. (18/7/18.)
173 969 Callender's Cable and Construction Co., Ltd., and Watson, J. F. Manufacture of electric cables and apparatus therefor. (31/12/20.)
173 976 Watkinson, J. Resistance switches for controlling the intensity of electric currents. (5/10/20.) (Cognate application 2 114/21.) (Divided application on 173 613.)
173 977 Gundry, W. L. D., and Lord and Shand, Ltd. Lighting gas by electricity. (15/1/21.)
158 245 Koppensteiner, Dr. K. Electric distribution systems. (31/12/19.)
162 642 Siemens and Halske Akt.-Ges. Mercury vapour jet pumps with electric arc. (24/4/20.) (Addition to 157 118.)
173 986 Mead, A. G., and Mead and Jeffery, Ltd. Electric incandescent lamps. (15/2/21.)
174 001 Reodie, L. N. (Consorzio per Elettrotrazione). Means for the suspension of electric contact wires. (15/4/21.)
169 442 Latour, M. Thermionic transmission systems for wireless telephony. (20/11/16.) (Divided application on 19 760/20.)
174 093 Furnival, J. M. Microphones or telephone transmitters. (20/10/20.)
174 094 Lee, F. W. R., Lee, E. R., and Golledge, V. F. H. Thermal switches for electrically-heated apparatus. (20/10/20.)
147 145 San Giorgio Soc. Anon. Industriale. Electro-hydraulic steering apparatus. (17/9/18.)
147 612 Schuchhardt Berliner Fernsprech und Telegraphenwerk. F. Device for strengthening telephone currents and other electrical oscillations. (14/5/17.) (Addition to 147 579.)
147 865 Columbia Graphophone Manufacturing Co. Dies or moulds for duplicating gramophone records and for like purposes. (14/8/16.)
148 182 Ges. fur Drahtlose Telegraphie. Reception of continuous electric oscillations. (15/10/15.)
148 380 Day, A. van T. Electric high-frequency signalling. (17/7/16.)
148 801 Huth Ges. Dr. E. F., and Kuhn, Dr. L. Apparatus for rhythmically influencing electric waves produced by cathode tubes. (3/4/19.)
148 804 Huth Ges, Dr. E. F. Switching arrangement for wireless signalling, particularly for aeroplane sets. (8/9/16.)
148 992 Ges. fur Drahtlose Telegraphie. Electro-magnetic wave-receiving arrangements. (8/2/16.)
149 011 Huth Ges, Dr. E. F. Wireless telephony. (31/12/17.)
149 013 Loewe, Dr. S. Installation for the operation of Röntgen tubes. (5/3/19.)
149 014 Huth Ges, Dr. E. F. Arrangement of connections for generating and receiving electrical oscillations. (2/5/19.)
149 195 Huth Ges, Dr. E. F., and Loewe, Dr. S. Method of connection to produce oscillations with vacuum tubes. (16/7/17.)
149 197 Huth Ges, Dr. E. F., and Rosenbaum, B. Antenna for wireless telegraphy. (14/7/15.)
149 198 Huth Ges, Dr. E. F. Connection for sending and receiving electric waves. (13/10/17.)
149 209 Huth Ges, Dr. E. F. Combined wireless transmitting and receiving arrangement. (15/12/17.)
149 211 Huth Ges, Dr. E. F. Electric discharge vessels. (29/12/17.)
149 214 Loewe, Dr. S. Wireless telephone transmitters. (29/10/18.)
149 215 Huth Ges, Dr. E. F., and Rosenbaum, B. Arrangements for the combined transmission and reception of wireless signals. (28/8/17.)
149 235 Huth Ges, Dr. E. F., Rosenbaum, B., and Loewe, Dr. S. Process for wireless telegraphy and telephony. (18/8/17.)
149 237 Loewe, Dr. S. Thermionic receiving-apparatus for wireless signalling. (18/4/18.)
149 240 Huth Ges, Dr. E. F. Thermionic receiving-systems for wireless and wired wireless signalling. (13/10/17.)
152 311 Loewe, Dr. S. Vacuum tube. (20/4/18.)
174 118 Line, W. J., and Tucker and Co., Ltd, J. H. Mounting clips for electric switch gear. (10/9/20.)
174 134 Taggart, J. Scott, and Radio Communication Company, Ltd. Negative resistance devices particularly for electro-magnetic wave systems and the like. (30/9/20.) (Cognate application 17 839/21.) (Patent of addition not granted.)
174 137 Painter, F., and Idge, G. H. Electric switches. (7/10/20.)
174 149 British Thomson-Houston Company, Ltd. (General Electric Company). Electron discharge devices for use as valves or oscillators. (13/10/20.)
152 355 Haddan, R. (Neumeyer Akt.-Ges. F.). Electric starters for internal-combustion engines. (13/10/20.) (Convention date not granted.)
174 156 Oldham, O., Oldham, G., and Oldham, J. Magnetic locks. (14/10/20.) (Cognate application 32 248/20.)
174 163 Glaser, W. H., Wickens, A. L., and Glaser, Ltd., W. H. Brush-gear for electrical machinery. (15/10/20.)
174 185 Oliver, V. F. M. Device for testing the electric ignition of internal-combustion engines. (19/10/20.)
174 192 Parson, Sir C. A., Bennett, E., and Rowe, H. Searchlight and other projectors. (20/10/20.) (Addition to 152 728.)
174 202 Hadwen, H. E., and Willis, H. Drop electric lamps. (23/10/20.)
153 002 Schaeffer, E. Method of operating vacuum tubes. (26/8/19.)
153 003 Schaeffer, E. Method of operating vacuum tubes. (24/10/19.) (Addition to 153 002.)
174 223 Igranic Electric Company, Ltd. (Cutler-Hammer Manufacturing Company). Electro-magnetically operated circuit-controlling devices. (2/11/20.)
154 582 Betulander, G. A. Call distributing arrangements for telephone plants. (22/11/19.)
174 242 Amberton, R., and Bray, E. N. Loose-handle electric circuit breakers, current limiters, overload releases, prepayment meter switches, and the like. (10/11/20.)
167 446 McKenzie, Holland, and Westinghouse Power Signal Company, Ltd. Alternating current relays. (6/8/20.)
156 496 Eustice, A. L. Renewable electric fuses. (31/3/19.)
174 279 Hodges, H. C. Fusible cut-outs and distribution fuse-boards for electric circuits. (6/1/21).
158 238 Soc. des Ateliers de Constructions Electriques du Nord et de l'Est. Electric systems of ship propulsion and the like. (25/5/15.)
174 298 Taylor, A. R. Means for supporting thermionic valves. (12/3/21.)

APPLICATIONS FOR PATENTS.

June 12, 1922.

16 199 W. G. Brown. Joint boxes for cables.
16 202 A. M. Taylor. Electric transmission systems.
16 226 E. W. Powell. Detachable filament for wireless valves, etc.
16 243 R. A. Jouaust. Reception of undamped oscillations. (22/6/21, France.)
16 249 G. C. Snijders. Telephone exchange systems. (14/6/21, Holland.)
16 268 Skywing Aircraft Corporation. Electric ignition devices. (1/12/20 United States.)
16 276 British Thomson-Houston Company. Motor control mechanism.
16 277 British Thomson-Houston and H. W. E. Liddiard. Control of electrical machines.
16 284 W. F. M. Rose. Mechanical transmitter for wireless telegraphy.
16 301 H. D. Nyberg. Galvanic cells. (28/3/22, Sweden.)
16 302 Scintilla. Lighting plants of motor vehicles. (13/6/21, Switzerland.)
16 303 Scintilla. Windings of electro-magnets. (9/7/21, Switzerland.)
16 305 W. H. Wilson. Radio communication, etc.

June 13, 1922.

16 351 A. Jones. Electric furnace.
16 362 W. B. Sayers. Electric conductors.
16 370 M. Plohl. Production of compensation voltage by self-induction and capacity.
16 376 Morkrum Company. Printing telegraph receiver. (13/6/21, United States.)
16 382 A. E. White (Elyria Iron and Steel Company). Electric cutt-welding machines.
16 398 L. Frost and W. Stubbs. Electric heaters. (13/7/21, Australia.)

June 14, 1922.

16 420 J. B. Tucker. Quick make-and-break switches.
16 434 A. E. Roberts and L. H. Thompson. Hornless cabinets for wireless recorders.
16 442 British Insulated and Helsby Cables, Ltd., and F. Mercer. Rendering line capacity of telephone cables uniform.
16 443 British Insulated and Helsby Cables, Ltd., W. Holttam, and F. Mercer. Elimination of overhearing or cross-talk in telephony.
16 447 W. Gee. Electrical device for giving set speeds to gramophones.
16 448 W. Gee. Revolving disc for electric motor and foot switch for dental purposes, etc.
16 450 A. S. Cubitt. Electric switches.
16 455 E. Curtis. Automatic electric signalling system.
16 472 L. G. Preston and G. Shearing. Signalling in wireless telegraphy.
16 477 Western Electric Company. Electric wave filters.
16 478 Western Electric Company. Automatic telephone switches. (21/7/21, United States.)
16 491 Siemens und Halske Akt. Ges. Telephone systems. (15/7/21, Germany.)
16 492 H. Barkes. Pipe and socket coupling for electric connections.
16 498 H. and O. Lucas. Automatic electric switches.
16 499 H. and O. Lucas. Brush-holders for electric machines.
16 518 Pittsburgh Transformer Company. Polyphase transformers.
16 530 R. S. Clay. Transmitting pictures by telegraphy.

June 15, 1922.

16 537 W. J. Polyblank. Electric couplings.
16 557 H. North. Electric lighting devices.
16 575 Sir O. J. Lodge and E. E. Robinson. Wireless telegraphy.
16 576 A. Orling, M. Compare and G. A. O'Hanlon. High-frequency selective wireless receiving apparatus.
16 577 A. Orling, M. Compare and G. A. O'Hanlon. Low-frequency selective wireless receiving apparatus.
16 578 A. Orling, M. Compare and G. A. O'Hanlon. Secret wireless intercommunication.
16 591 F. E. Pernot. Electric signalling.
16 614 W. J. Evans and E. F. Joyce. Portable electric boring machines.
16 626 Metropolitan-Vickers Electrical Company, J. P. Campbell, L. Miller, and F. B. Holt. Electrically operated valves.
16 642 Quarzlampen-Ges. Electric heat radiator for therapeutic purposes. (15/6/21, Germany).
16 649 Skywing Aircraft Corporation. Ignition systems. (1/12/20, United States.)

June 16, 1922.

16 664 F. Lehner and I. Rosenstok. Two-piece glow lamp bulb.
16 665 G. Frieman and A. H. Kirby. Telephone transmitters, etc.
16 668 H. S. Jones. Apparatus for cutting off electric supply at a given time.
16 671 W. T. Turner. High-tension magneto electric machines.
16 677 Veritys, Ltd., and F. W. Thorpe. Anti-vibration fittings for electric lamps, etc.
16 682 Electric Control, Ltd., and O. Ellefsen. Electric transforming machinery.
16 701 S. T. Hosken. Electric signs.
16 702 Norwest Electrical Manufacturing Company. Safety device for electrical apparatus.
16 709 British Thomson-Houston Company (General Electric Company). Insulators.
16 713 A. A. Price. Generating sets.
16 716 P. G. A. H. Voigt. Attachments to valve detectors for wireless telegraphy, etc.
16 717 O. Morduch. Rotating electric machines.
16 718 C. Davis. Wireless direction finding apparatus.
16 733 Peckham Truck and Engineering Company and S. Thomas. Trucks for tramcars, etc.
16 747 Soc. Anon. Electricite et Electromechanique. Electric welding. (11/5/22, Belgium).

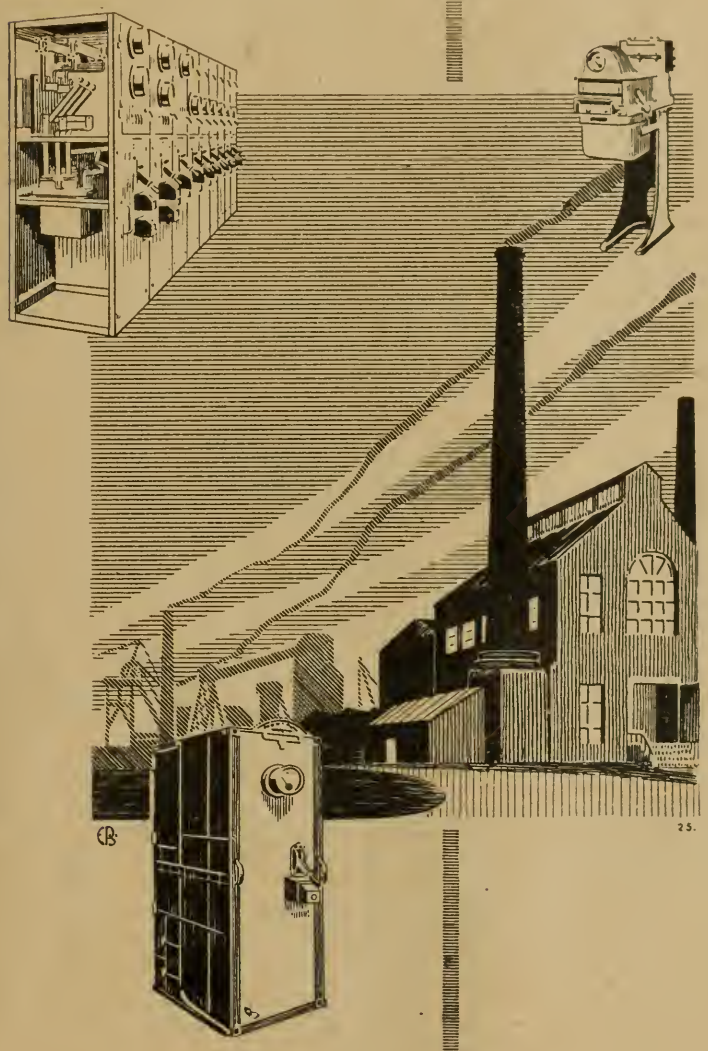
June 17, 1922.

16 757 W. W. Wilson. Electrodes for welding, etc.
16 758 A. R. Angus. Telegraph and telephone devices.
16 776 J. H. Parr. Electromotors.
16 794 T. G. Hodgkinson. Oscillatory electric circuits.
16 796 British Thomson-Houston Company (General Electric Company). Incandescent arc devices.
16 797 L. Vallino. Overhead switches for electric trolley conductors. (18/6/21, Italy).
16 804 Erda Ges. fur Wissenschaftliche Erderforschung, R. Ambronn. Devices for locating masses of dissimilar electric conductivity over the earth, etc. (17/6/21, Germany.)
16 821 Sir C. A. Parsons and J. Rosen. Electric machines.
16 826 Siemens-Schuckertwerke. Electrical metal-vapour apparatus. (18/6/21, Germany.)
16 827 J. C. W. Drabble and L. G. Preston. Receiving arrangements for wireless telegraphy and telephony.

The Editorial, Advertisement and Publishing Offices of "The Electrician" are at 8, Bouverie Street, London, E.C. 4. Telegrams: Benbrotric, Fleet, London. Telephone: City 9852 (6 lines).

The subscription to "The Electrician" is £1 5 0 per annum in the United Kingdom and £1 10 0 per annum Abroad. Advertisement Rates can be obtained on application to the Manager. Advertisement copy and blocks should be received on the Friday preceding date of publication.

SWITCHGEAR



"THE PROOF OF THE PUDDING"—

F.P. Switchgear installations elicit many gratifying testimonials :

"We have used a very considerable number of your cubicles.

"The behaviour of your gear, at all times, has been exceedingly satisfactory, and the general finish and substantial character of the cubicle and its contents have given us complete satisfaction.

"We are convinced of the general superiority of your proposition"

—A Northern Corporation Electricity Dept.

"Very satisfied with the appearance and workmanship."

—An Eastern Counties Corporation Electricity Dept.

"Very pleased with the general appearance and standard of work."

—A Midland Corporation Electricity Dept.

Thirty H.T. remote control switches, after 10 years' service during which many short circuits have been successfully dealt with, still stand up to the work satisfactorily in spite of the load having trebled.

—Précis of a letter from a North-Western Corporation Electricity Dept.

"As good a job as I have yet seen."

—A comment by a very well-known engineer on the sixth extension to a 40,000-volt F.P. installation in North Wales.

"Real top-hole stuff—about the best switchgear made."

—A prominent engineer's opinion of F.P. Switchgear.

"Very high-class quality. . . Do not recollect ever seeing a better turned out job."

—A large electric supply corporation in Australia.

F.P. Switchgear comprises :

SWITCHBOARDS.

CUBICLE SYSTEM : Sheet Steel, stone work or trunk types; L.T. to E.H.T.

UNIT SYSTEM : Industrial and mining pattern for wall or floor mounting.

PANEL SYSTEM : Open type for all outputs. Factory and Ship patterns.

COMPONENT EQUIPMENT.

SWITCHES : Isolating switches, knife switches, ironclad switches, and fuses.

OIL SWITCHES AND CIRCUIT BREAKERS.

PILLARS : For equalising, exciting and regulating, or synchronising.

REACTANCE COILS.

EARTHING RESISTANCES.

CABLE BOXES AND ADAPTERS.

The services of our staff engineers, with long experience and specialised knowledge in switchgear problems, are always at your disposal.

We invite your enquiries.
Our prices are competitive.
